W. H. CAMP[1] has given powerful voice to the view that the species and other categories below the rank of family recognized in the codes of zoological and botanical nomenclature may well prove unserviceable as an instrument to describe the rich complexity of the units revealed by modern studies in micro-evolution and experimental taxonomy. "Our present system of nomenclature," he wrote, "was designed to fit a concept of static genera and species. Tinker with it as we will, we cannot re-tailor this mouldy shroud into something which will serve as an adequate nomenclatural covering for the complex, living groups which we are now beginning to realize must be defined. No one knows exactly what this system will be; as yet, one can see only a general outline, for our knowledge is too scant to permit a filling in of all the details."

In a communication to the British Association at Edinburgh in 1951[2] I strongly supported this view, and in a more recent paper[3], Prof. J. Heslop Harrison and I have put forward a tentative scheme, based on the suffix 'deme', for a new system of categories to express the findings of experimental taxonomy. In this last paper, the position of the species in relation to the deme terminology was briefly discussed. We stated that, in constructing our terminology, we had "rigidly excluded the categories of orthodox taxonomy", but we emphasized this did not mean that "we regard the terms genus, species, etc., as in any way outmoded. On the contrary, they will continue to remain essential as expressing the basic outline of living things and as a framework into which other classifications can be fitted". This view was further developed by both of us at a conference organized by the Botanical Society of the British Isles in 1954[4].

In the present article, I want to discuss more fully this question of the position of the species in relation to a system of categories for experimental taxonomy, and to put forward suggestions as to the future role of the species concept in biological taxonomy.

The term 'species' was first used more or less in its modern sense during the seventeenth century, and John Ray, in 1674, was among the earliest to lay down criteria for the assessment of specific differences. During succeeding years the concept gradually became stabilized to denote the basic units of biological classifications—the units, in fact, on which classification operated. These units were regarded by the great majority of biologists as static entities, created once and for all; the task of the systematist was to look for them, to recognize them for what they were, and to group them into higher categories. John Lindley, who took a more naturalistic view of plant classification than many of his contemporaries and who described "genera, orders, classes, and the like, as mere contrivances to facilitate the arrangement of our ideas with regard to species", looked upon species themselves as "created by Nature", and this view, with varying degrees of theological adornment, may be taken as typical of the pre-Darwinian systematic biologists. The idea of species as discrete, specially created, entities was no doubt unconsciously reinforced by binary nomenclature with its superficial resemblance to personal human names like John Smith, and, by the middle of the nineteenth century, the species had become unshakeably enthroned in the centre of taxonomic thought.

With the general acceptance of the theory of evolution during the second half of the nineteenth century the history of the species concept entered a new phase—a phase from which it has not yet emerged. In view of its firm entrenchment, it was inevitable that the term species should have become at once accepted for the basic unit of evolutionary change—an acceptance that was, of course, of great value during the formative years of evolutionary theory and without which the theory could scarcely have developed.

It was not long, however, before it became clear that the species of pre-Darwinian taxonomists represented a number of very different types of unit from an evolutionary point of view. The existence of such different types had, of course, long been recognized, and the 'lumpers' and 'splitters' represented two extreme reactions to this fact; but it was not until the acceptance of evolution, and especially the development of genetics and cytology during the past fifty years, that the reasons for these differences began to be appreciated.

The reaction to this appreciation took the form of attempts both to define the species in modern evolutionary terms, and to set up new categories to supplement or replace it. With regard to the former, there has been a growing realization that, owing to the disparate nature of the units usually classed as species, it is not practicable to choose an evolutionary definition that is of use in more than a very limited sphere. For example, a definition based on inter-sterility leads, in some cases, to the separation of individuals practically indistinguishable morphologically. Such a definition clearly renders the species concept virtually useless to general biologists and others requiring an easily applicable and stable basic unit for taxonomy. These difficulties led to the second type of reaction, namely, the construction of special categories to express the new knowledge that was being accumulated. Such categories took the form either of modifications of the term 'species' (for example, Turesson's "ecospecies" and "coenospecies"), or of completely new terms (for example, Danser's "commiscuum", "comparium", etc.), but in either case their relationship to the species itself was far from clear and has led to much subsequent controversy.

In our paper on the deme terminology[3], Heslop Harrison and I gave reasons, based on the nature and purpose of classification in general, for favouring a complete separation between the categories of nomenclatural taxonomy and those of experimental taxonomy. This course has, I think, very definite advantages for both of the resulting category systems. With regard to experimental taxonomy, there is no doubt that the term 'species', however conscientiously one tries to forget its past associations and to adapt it to modern ideas, still comes to us trailing clouds of special-creation glory, which, as Camp has indicated, tend to bedevil its use in an evolutionary setting. It is largely these wisps from the past that have caused so much controversy over the relationship between nomenclatural and experimental taxonomy. The problem of whether to adapt or to abandon a particular term is a familiar one in the history of thought, and which course should be taken depends on the adaptability of the term and the extent of the change that has taken place. For example, the humours of medieval medicine developed quite happily into the present-day bad and good humour of our dispositions, whereas phlogiston, which could not be adapted to modern science, is dead—and the word 'dryads' is not now employed to explain the behaviour of *Quercus robur*. On balance, the abandonment of the term 'species' as a category to express the findings of experimental taxonomy, reflecting a clean break with the non-evolutionary past, would seem to be the right policy. The reluctance of geneticists and others to take this step is, perhaps, bound up with a lingering belief that species are, in some way, 'real entities', not 'artificial constructs of the human mind' as are other taxa. This belief makes it seem unthinkable to abandon the term for such an important branch of biology as the study of micro-evolution. If, however, 'real entities' and 'artificial constructs' are regarded, not as mutually exclusive, but as alternative descriptions, each valid in its own context, this difficulty disappears. Such an approach has recently been fully developed by R. Crawshay-Williams in a most stimulating book[5].

The policy I am advocating is strongly reinforced by a consideration of the continued use of the term in nomenclatural taxonomy. Clearly, there will always be a need for a general-purpose classification, based primarily on morphology, for those who require a broad map of the diversity of living things. For this purpose, the nomenclatural categories of genus, species, variety, etc., are excellently suited, and it would be a great advantage if they were not subject to continued attempts to bring them up to date and to re-define them in evolutionary terms. Let them be regarded, frankly, as mainly morphological categories based on degree of difference and they will perform their proper function in biological classification. Such a view would lead to a reduction in the number of name changes made for taxonomic, as opposed to nomenclatural, reasons. For if it was agreed that genera and species should be regarded as broad, flexible categories, with a considerable element in them of convenience, biologists would not be so constrained to alter the limits of existing taxa in order to fit them to a particular taxonomic theory. This policy will, I know, strike many biologists as lessening the stature and importance of nomenclatural taxonomy. This is true only in the sense that, at the specific, or in some cases the generic, level detailed micro-evolutionary knowledge, when available, would be embodied in special categories, leaving the nomenclatural categories free to give a general purpose account of the variation of the organisms concerned. This does not mean, however, that attributes such as intersterility and chromosome number would be rigidly excluded as criteria for the nomenclatural categories; if they can be incorporated as supplementary to morphology without destroying the general utility of the classification the additional information thus embodied would be, of course, a valuable asset.

The suggestions outlined in this communication are an attempt to crystallize into a definite policy some of the rather ill-defined ideas that are in the air on the defects of present-day taxonomic theory and practice. They are put forward in the hope that others will be stimulated to think about them and discuss them, too, with the view of evolving a generally agreed policy.

PHYSICS OF WATER AND ICE

THE discussion on "The Physics of Water and Ice", held at the Royal Society on November 14, was particularly timely. In the past two years there has been a renewed interest in both the experimental and theoretical aspects of ice and water in relation to their physical properties and their structure. On the theoretical side it has been evident for some time that the picture of ice and water as essentially regular and irregular arrangements, respectively, of water molecules tied together tetrahedrally by hydrogen-bonds is only a rough first approximation. Certainly it is inadequate for the degree of detail now required to define the properties of these substances. It is especially true for the properties that are so-called 'structure sensitive', that is, that depend on the variation of the crystalline material from its ideal state. At the same time, the practical interest in ice and water has been increasing from a number of fields, notably from glaciology, from the technical aspects of the icing of aircraft and aircraft engines, and perhaps most of all from meteorology, where it is now evident that the processes of conversion of water-drops into ice is fundamental for the phenomena of rain and thunderstorms. In the latter connexion it is interesting that a new type of interdepartmental co-operative research has now been going for three years at the Imperial College of Science and Technology, London, some of the main results of which were reported at the meeting. The meeting was not primarily concerned with the theoretical aspects of the hydrogen-bond, which had been recently covered in a discussion of the Section of Physical Chemistry of the International Union of Chemistry, at Ljubljana; nor with that of aqueous solutions, also recently dealt with at the Faraday Society meeting at Oxford. However, some of the leading Continental experts attending both those conferences also took part in the Royal Society discussion, and gave more details of their work in the field of pure water and ice.

Underlying all studies of ice is the knowledge of its structure at different temperatures. A critical survey of the data now available was given by Dame Kathleen Lonsdale (University College, London) in the opening paper, in which she discussed the results of the latest X-ray, electron and neutron diffraction experiments, both for ordinary and for heavy ice. Both substances show some degree of differential contraction along the a- and c-axes on cooling, tending to make all the intermolecular distances of the water molecules in ice more nearly equal at the lower temperatures. This result, however, seems to contradict that reported by Dr. R. W. Powell, of the National Physical Laboratory, on the basis of careful interferometric measurements of the coefficient of expansion of large single crystals of ice in two directions. Such discrepancies, however, are not unknown in other instances, and there seems to be a systematic difference between X-ray and macroscopic measurements of thermal expansion, possibly due to crystal imperfections. However, the work ought to be repeated by both methods, preferably on the same specimen.

The neutron-diffraction work of H. A. Levy, of which a report was heard at the Discussion, indicates an almost completely random position for the protons along the hydrogen-bonds, corresponding to the picture given by Pauling, but Dame Kathleen Lonsdale pointed out that slight deviations from randomness could not easily be detected by this method.

Dr. G. B. B. M. Sutherland reported studies on the infra-red absorption of single crystals of ice, which he had carried out in conjunction with Dr. Ockmann. Over most of the frequencies concerned there seem to be very little preferred orientation and this would also favour an almost isotropic random hydrogen-bond structure for ice.

Prof. W. C. Price (King's College, London) reported some infra-red absorption studies of water adsorbed on alkali halides. Observed shifts in the frequencies of the 3,000-cm.$^{-1}$ band were interpreted in terms of water molecules attached by hydrogen-bonds to the negative ions. With thicker layers of adsorbed water, bands appear in the 2,000-cm.$^{-1}$ region, corresponding to molecular deformation plus a libration of the molecule against the forces of association with other molecules. Body-centred alkali halides show additional bands which suggest attachment of water to positive ions.

Dr. G. J. C. Frohnsdorff and Dr. G. L. Kington, working in Prof. R. M. Barrer's department in the Imperial College, reported some interesting thermodynamic and spectroscopic properties of water contained in the pores of synthetic zeolites, where up to twenty-one molecules of water can be accommodated. Here a transition can be observed between a predominantly adsorbed pattern on slight hydration, to a water-like pattern occurring close to saturation.

An important paper was read by Dr. H. Gränicher, reporting the studies of the Zurich school on the relaxation process, particularly dielectric relaxation in ice. Dr. Gränicher attributes part only of these phenomena to the presence of hydrogen ions in the form of oxonium and hydroxyl ions. He also postulates the presence of what he calls L- and D-protonic defects in ice in which the oxygen atoms are only slightly displaced. L-defects consist of two neighbouring oxygen atoms between which there is no proton ; in D-defects two protons are more or less collinearly arranged between oxygen atoms. These types of defects are assumed to wander through the crystal structure, to be created and to neutralize each other. In this way good agreement is achieved with the new experimental results on the variation with frequency of the dielectric constant of ice at different temperatures. A theoretical treatment of lattice defects in relation to the mechanical relaxation of ice was given by Dr. R. Bass of Stuttgart.

The work of the Göttingen school was presented by Dr. L. De Mayer—Dr. M. Eigen, who is largely responsible for it, being unfortunately too ill to attend. It has long been known that the electrical conductivities of pure water and pure ice are of the same order of magnitude, and it is assumed that this is because the mechanisms operating in the two cases are similar. The Göttingen workers have managed to measure separately the number of ionic carriers, namely $(OH_3)^+$ and $(OH)^-$ groups, and their apparent velocities. They find that the number in ice is only a small fraction of that in water, and consequently the apparent velocity of hydrogen ions in ice must be many times as great as in water. As the velocity of hydrogen ions in water is already much higher than that of any other ion, and is clearly due, as Fowler and Bernal showed twenty-five years ago, by some form of relay mechanism, proton-transfer in ice must be by a similar mechanism, operating not over one hydrogen-bond but over a chain of hydrogen-bonds. This is very similar to electron-transfer in metals, and a close analogy exists between the two phenomena. It is even possible, by the introduction of fluorine ions, to produce what are equivalent to p- and n-junctions for ice, with protons taking the role of electrons in semiconductors. This work obviously opens up a very exciting field of theory which may have particular application in biology, following some recent suggestions by Szent-Györgyi.

Prof. H. S. Frank (United States) discussed the significance of some of the results already reported in terms of the nature of the hydrogen-bonds in water and ice, pointing out that the influence of the bond itself on the lone-pair electrons on the other side of the molecule leads to a general strengthening of the bond, and provides some explanation for the closer approximation of the properties along the a- and c-axes at low temperatures. This also goes some way to explain the very peculiar fact that the cubic form of ice, which has a diamond structure at first sight essentially similar to the wurzite structure of hexagonal ice, is not stable above − 110° C.

Turning now to the structure of water, Dr. C. L. van Pantaleon van Eck reported some very careful work recently carried out at Amsterdam on the X-ray diffraction patterns of water and on its infra-red absorption. His conclusions are that in the water-structure there are approximately six molecular neighbours at distances varying from 3·0 to 3·4 A. from any given molecule. It is not clear why this result is different from that obtained by Warren and Morgan in 1938, who found four molecular neighbours at 2·85 A. Dr. van Eck's interpretation would imply a collapsed tetrahedral structure not unlike that of metallic tin in relation to grey tin. He bases an independent calculation of the intermolecular distance in water on the absorption spectrum of HDO, in which the band at 3,500 cm.$^{-1}$, unlike the corresponding bands for ordinary and heavy water, is free from overlapping and permits an estimate leading to the value 2·85 A., as opposed to the hydrogen-bond distance of 2·76 A. found for ice. If this is the case then the hydrogen-bond in water would be considerably weaker than that in ice, of the order of 5 instead of 6 kcal./bond mole, and it would not be necessary to postulate any actual breaking of hydrogen-bonds on melting. These results throw open once more the whole question of the structure of water, and clearly much more experiment and calculation are necessary.

Dealing with the transitions from water to ice, and from water-vapour to ice, two papers were read by Dr. B. J. Mason, representing the work of the Imperial College group. In the first Dr. Mason gave a full acount of the extremely beautiful method which he has developed for growing small crystals of ice at controlled temperatures and water-vapour concentrations in a thermal-gradient air box. He has shown that temperature alone determines the particular habit adopted by ice crystals, except at high supersaturation when dendritic growth occurs. In the temperature ranges from 0° to − 3° C., from − 8° to − 12° C. and from − 16° to − 25° C., hexagonal plates are the rule. On the other hand, from − 3° to − 8° C., and below − 25° C., the predominant form is either the elongated hexagonal prism or the hollow prism which sometimes has a spiral structure. The fern-like dendritic crystals occur only between −12° and − 16° C. By growing crystals successively at different temperatures Dr. Mason has succeeded in producing combined forms which reproduce many of the beautiful effects long known in snowflakes, which may be interpreted as indicating the various temperature regimes through which the snowflakes moved during their formation. These observations are of fundamental meteorological importance and also of great physical interest, because until now very little work has been done on the influence of temperature on crystal-form, and it would appear that the sharp changes of habit with temperature indicate that we are dealing here with a thermodynamic phenomenon depending on the relative values of the free energy of growth in different habits, as Prof. J. D. Bernal suggested at the meeting.

Dr. Mason's other paper described a series of carefully controlled experiments, on the supercooling and freezing of water drops. He showed two curves relating the volumes of drops to the temperatures at which they froze—one for freezing induced by nuclei, and another for the case in which nuclei are absent. In the latter case supercooling for drops as small as 1μ in diameter can be effected down to − 41° C. and for 1-mm. drops down to − 33° C. Crystallization at these temperatures is an almost explosive process, resulting in the fracture of the frozen droplet and its shattering, a phenomenon which may be of great importance for the rapid spread of nucleation through super-cooled clouds in the atmosphere.

Dr. M. Blackman (Imperial College, London) reported a study by electron diffraction of epitaxial growth of ice on silver iodide crystals. Silver iodide is the only substance at present known to be capable of producing rapid nucleation of ice. By controlled growth of single crystals of ice, Dr. Blackman has been able to show the crystal formation of the ice with sufficient penetration to bring out the underlying silver iodide lattice.

J. D. Bernal

MIDDLE EAST TECHNICAL UNIVERSITY, ANKARA

By Dr. TURGUT YAZICIOGLU

THE foundation stone of the Middle East Technical University in Ankara was laid on October 3, 1957, in the presence of the President of the Turkish Republic, the Prime Minister, the Minister of Education, the heads of the foreign aid committees, the Ambassadors of Great Britain and of the United States of America and other distinguished guests.

The University has, in fact, been working temporarily in a building in Ankara for two years. In 1956 there were 175 students attending the Colleges of Architecture and Administration, and in February 1957 the College of Engineering was established, followed in September by the creation of a research department for nuclear physics.

Foundations for colleges of mining, geology, agriculture and forestry were laid in 1956, and in 1958 students of electrical engineering, mining and geology will be admitted.

There are at present five foreign professors at the University, but arrangements have been made for further staff to be recruited through the United Nations (including two professors of architecture and one of administration), through Unesco (including professors of construction engineering, and of machinery), and through the technical aid programme of the British Government (professors of physics and of electrical engineering).

Thus by this year there will be altogether twelve foreign professors on the University staff; the Turkish teaching staff will number thirty.

The site designated for the construction of the Middle East Technical University is about three miles from Ankara and covers an area of about 4,500 hectares (11,115 acres). The University campus will comprise, besides the college buildings, dormitories, faculty housing, libraries, a theatre, sports grounds, restaurants and other accommodation. All the plans and projects have been drawn up by the Turkish Ministry of Works in co-operation with the University of Pennsylvania.

According to the first ten-year programme, the University will have about 6,000 students, 2,500 teaching and research staff, and forty departments (including teaching and research units) at the end of the first decade.

During this ten-year period the Turkish Government is to make grants to the University totalling 265 million Turkish lira (about £33 million), of which almost half will be invested, while over the same period foreign aid will be available to a total of 26·5 million dollars. In addition, the British Ambassador, in his speech during the inaugural ceremony, promised a further sum of £25,000 from the British Government in the present year.

The University is designed to fulfil the need for an international centre of higher learning to serve the requirements of the developing Middle East. It is founded on the belief that the development of the region in a manner satisfying the demands of a progressive society requires the integration of techniques with human needs and aspirations. The University considers its major responsibility to be the training of a growing number of educated men and women, able to work creatively on the problems of the Middle East, using the most advanced techniques of our era.

History of the University

Constituted as a university only since January 13, 1957, the Middle East Technical University now has two faculties. From the single group of fifty students, with which the teaching programme opened in November 1956, the Government of Turkey plans that the University shall grow to major size, involving six faculties, with a complete research establishment matching the academic activities of each department with a programme of applied research and development work in industrial and agricultural problems. The University's teaching programme, conducted in English, with its emphasis on unity of thought and action, and on the correlation of teaching and research, should make it an institution unique in the Middle East.

The first step in the establishment of the University was taken in 1953, when a survey of building and planning legislation revealed the need for university-trained technical people in the professions. As a result of this survey, a school of architecture and town-planning was suggested, to be integrated with research institutes in building and planning. A complete programme for the school was prepared by a United Nations Mission, under the direction of Dr. G. Holmes Perkins, dean of the University of Pennsylvania School of Fine Arts.

The Perkins Committee received not only the enthusiastic and energetic support of the President of Turkey, the President of the Grand National Assembly and the Prime Minister, but also the effective co-operation of a committee for the school, headed by the Minister of Education, and having as members Mr. Vecdi Diker, Mr. Ahmed Tokus, Mr. Mihat Yenen and Mr. Adli Yener.

Following the Perkins Committee recommendations, a request was submitted to the United Nations for assistance in establishing the first faculty. In the autumn of 1956 the Committee was reactivated by the Minister of Education as an acting Board of Trustees. Under its guidance, the programme of the University has been developed and its teaching operations begun. Fifty students first received instruction in architecture on November 1, 1956, in a rented building at 18 Müdafaa Caddesi, in Ankara. The formal inauguration ceremony was held on November 15.

During the winter, plans were made for expansion of the teaching facilities and the acquisition of a campus. On January 13, 1957, a provisional law authorizing the establishment of the University was passed by the Grand National Assembly. The Minister of Education has set aside a magnificent site for the development of a teaching and research centre, and plans for the construction of University facilities are moving ahead at top speed.

Since the beginning of the spring term 1957 the second faculty, that of engineering, has been in operation. Its first Department, of Mechanical Engineering, was joined by a Department of Civil Engineering last autumn. At the same time, the faculty of administration was opened. Continuing to develop in this way, all six faculties with their research institutes will, it is hoped, be in existence within five years, permitting rapid expansion toward the goal set by the Government.

OBITUARY

Viscount Waverley, G.C.B., O.M., G.C.S.I., G.C.I.E., F.R.S.

There have been many tributes to the outstanding qualities of mind and character which made John Anderson, the first Viscount Waverley, one of the greatest, beyond all question, of the many great public servants of Great Britain. It may be doubted, however, whether any of the numerous accounts of his remarkable career have yet done full justice to the special nature of the service which he was qualified to render to the nation, especially in two world wars, by his experience as a student of science at Edinburgh and a postgraduate research worker at Leipzig, before he entered the Civil Service. It should be understood that this course of scientific studies and practice in research did not serve him as a mere introduction, or a stepping-stone, to an official and ministerial career of such extraordinary distinction, in which he became a permanent Under-Secretary of State (Home Office) by the time that he was forty, governor of Bengal ten years later, and then, as Member of Parliament for the Scottish Universities, Minister for Home Affairs and Home Security, Lord President of the Council and, finally, Chancellor of the Exchequer, during the Second World War. Through it all, and with his imperishable and comprehensive memory as a background, the supreme importance of scientific progress had remained with him a matter of central interest and conviction. It was no mere matter of curious coincidence that the subject for his postgraduate researches and Ph.D. thesis at Leipzig had been the chemistry of uranium, and that nearly forty years later, and behind the densest curtain of war-time secrecy, he had found himself charged with the chief responsibility, on behalf of the War Cabinet, for Britain's part in the development of researches on atomic energy—primarily, of course, for purposes of war, but with an ultimate view, even then, to peaceful applications.

My first encounter with the future Lord Waverley was soon after the outbreak of the First World War, in 1914. Sir Robert Morant, as chairman of the English Health Insurance Commission, had found himself suddenly faced with the abrupt disappearance of all the important drugs which had been obtained from Germany; and he promptly recognized that in John Anderson, a brilliant young Civil servant, with the then almost unique qualification of scientific training and experience, he had the man to deal with the position thus created. I had newly joined the scientific staff of the then embryonic Medical Research Committee (now Council), and its first secretary, Walter Fletcher, had asked me to act on its behalf with reference to the same emergency; so that Anderson and I naturally met and kept contact over problems of common interest and responsibility. He also became a member, and a most important one, of a Royal Society Committee, appointed to enlist scientific co-operation to meet sudden needs of the same kind. Thereafter he was swept away to heights of administrative promotion where I lost direct touch with him; and it was not, indeed, until the Second World War that I came again into even closer scientific and personal contact with him, and then mostly 'behind the scenes'.

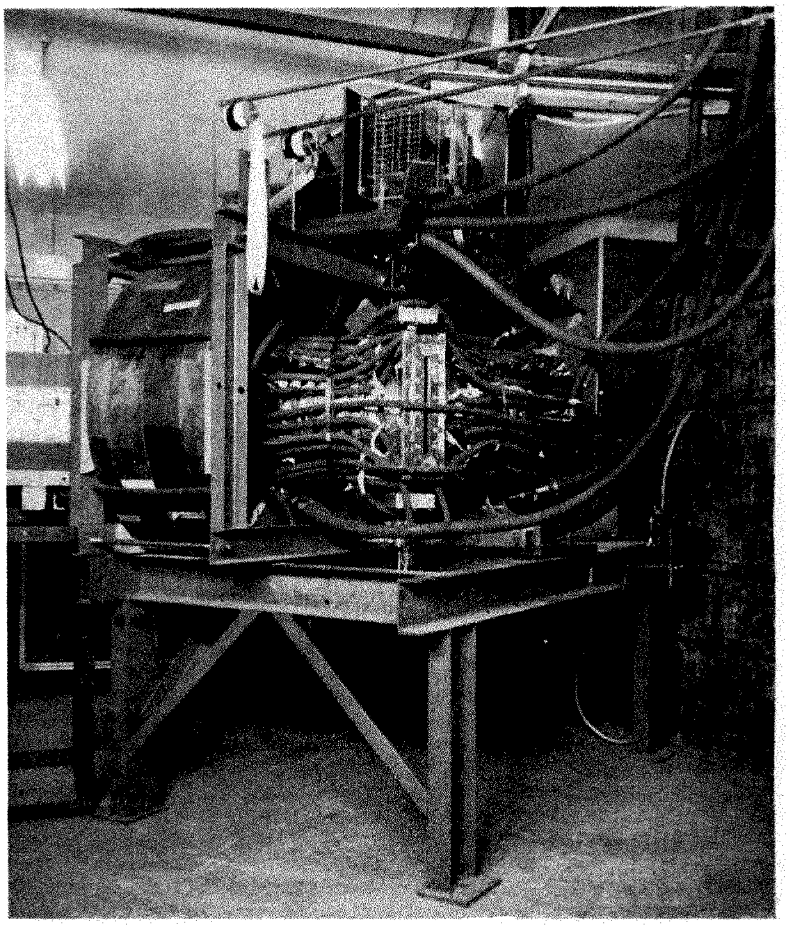
When the university memberships were abolished, Sir John Anderson, having no real interest in party politics, retired from parliamentary life until he entered the House of Lords. He became chairman for his remaining years of the Port of London Authority; and he continued to give practical evidence of his interest in scientific matters, not only as a director of Imperial Chemical Industries, Ltd., but also through a variety of honorary services to science, such as those of chairman of the Parliamentary and Scientific Committee, treasurer of the Lister Institute and president of the Research Defence Society. Nobody who was privileged to work closely with him could have failed, I think, to become aware that, behind the mask of his almost legendary reserve and quiet assumption of authority, Lord Waverley retained a generous and even emotional attachment to science and its claims, though an open display of such an enthusiasm was scarcely within his range.

H. H. Dale

NEWS and VIEWS

SCEPTRE III

Following the article by Allen, Allibone *et al.* in *Nature* of January 25, p. 222, we publish a photograph of SCEPTRE III. The photograph shows part of the 4-ton strip steel core threading the torus. Each half of the core has an eight-turn winding carrying 50 amp. d.c. to provide flux biasing. The primary, consisting of eight separate windings of eight turns each, is wound as uniformly as possible over the surface of the torus. The torus has a bore of 12 in. and is made of ½-in. thick aluminium in four quadrants, or sectors, separated by four straight sections each 6 in. long, which provide viewing and pumping facilities. The eight insulating gaps are protected by eight pairs of interlaced copper liners, and double vacuum gaskets made from indium wire are used throughout. Quartz-covered slits—one in the vertical plane and one horizontal—allow the discharge to be viewed by a high-speed rotating mirror camera. The primary windings are arranged to obscure these slits as little as possible. The toroidal magnetic field is created by providing a d.c. supply to 102 layer-wound coils placed around the torus perimeter beneath the primary winding, and at pumping and viewing ports the field is maintained constant by compensating coils. At the maximum B_z field of 1,000 gauss some 125 kW. are dissipated, and since these coils are not water-cooled the time of operation of the apparatus is limited by the temperature rise of these coils. The capacitors can be discharged into SCEPTRE III 40 times a minute, and about 100,000 discharges have been produced without noticeable deterioration of the torus lining. The terminating-circuit of the radio-frequency pre-ionizing supply is seen mounted above the core, and the water-cooling feed lines and a lead chamber containing the nuclear detectors are on the right.



Dr. J. R. Killian, jun.

As special assistant for science and technology to the President of the United States, Dr. James Killian brings to that post, specially created for him last November, a good deal of scientific and administrative experience. The position was described by President Eisenhower, in his address on "Science and National Security" on November 7, as one in which the incumbent, "aided by a staff of scientists and a strong advisory group of outstanding experts . . .", would "have the active responsibility of helping me follow through on the (scientific and development) programme". Thirty years ago, at the age of twenty-three, Dr. Killian took his degree of bachelor of science in business and engineering administration. The course for that degree covered many aspects of engineering and science and also comprised training in engineering and scientific management. Since then, his work in research and administration has won for him many honours and awards, including the President's Certificate of Merit in 1948, the Freedoms Foundation Award in 1952 and a Certificate of Appreciation from the Department of the Army in 1953.

Dr. Killian is a Fellow of the American Academy of Arts and Sciences and a member and former vice-president of the American Society for Engineering Education. In 1951, he was appointed chairman of the Army Scientific Advisory Panel and a member of the Scientific Advisory Committee of the Office of Defense Mobilization. Dr. Killian went to the Massachusetts Institute of Technology from Trinity College (now Duke University) in 1923, and while he was editing its newspaper, *Technology Review*, was made executive assistant to the Institute's president, the late Dr. Karl T. Compton. Two years after this appointment, in 1939, he was helping Dr. Compton to organize the Institute's vast programme of training and research for war purposes; ten years later, Dr. Killian succeeded Dr. Compton as president of the Institute.

College of Aeronautics, Cranfield : Prof. John Loxham

Mr. John Loxham has been appointed to the chair of aircraft economics and production in the College of Aeronautics, Cranfield. He will take up his appointment on April 1. Mr. Loxham, as managing director of the Sigma Instrument Co., Ltd., has been responsible for the development of a wide range of fine measuring equipment specially suited to the production methods of modern industry, and those of the aero-engine industry in particular. His work in this field has earned him an international reputation, and machines made to his designs are used in all the industrialized countries of the world. Before joining the Sigma Company in 1939, Mr. Loxham was head of the Engineering Production Department at the Northampton Polytechnic, London, where he established the first National Certificate course in production engineering, and set up the first technical college machine tool laboratory. He is chairman of the British Standards Institution Committee for Limits and Fits, and a member of several other committees. He has lectured in Great Britain and abroad on subjects associated with management, technical education and the control of quality in engineering production. In 1946, he was awarded the Sir Joseph Whitworth Prize by the Institution of Mechanical Engineers for his paper on "An Experiment in the use of a Standard Limit System", and the City and Guilds of London Institute has recently conferred upon him the Insignia Award in Mechanical Engineering for 1957 in recognition of his work in the field of precision engineering.

Horticulture at Reading : Prof. O. V. S. Heath

Dr. O. V. S. Heath, who has been appointed to the chair of horticulture in the University of Reading, graduated in botany in 1925 at the Imperial College of Science and Technology, London, and proceeded to the Imperial College of Tropical Agriculture, Trinidad, for a course in tropical crop botany. During 1927–36 he held the post of plant physiologist at the Cotton Experiment Station, Barberton, South Africa, and carried out developmental studies on cotton in relation to soil moisture, rotations, and cultivation methods. In 1936 he returned to the Imperial College as Leverhulme Research Fellow and began work on carbon dioxide assimilation in relation to stomatal aperture, and the mechanism of stomatal movement which from then on became his major field of work. In 1939, he was appointed to the staff of the Research Institute of Plant Physiology at the Imperial College and attained the rank of senior principal scientific officer. During 1940–45 he carried out research on morphogenesis in the onion plant, especially the effects of day-length and temperature on bulb formation and flowering. Techniques for producing onion sets and for preventing bolting by storage treatment were devised, and low-bolting strains selected. From 1945 onwards Dr. Heath resumed his stomatal investigations. The discovery of the effects of carbon dioxide concentration led to work on the minimum concentration of carbon dioxide in illuminated leaves. In the field of stomatal physiology Dr. Heath's work is unrivalled. His recent demonstration of the role of chelation in the action of growth substances has opened a new line of approach. He took an active part in the work of the department both as lecturer and supervisor of postgraduate students.

The Atomic Energy Authority

Replying for the Prime Minister to a question in the House of Commons on January 24, Mr. R. A. Butler said he had no reason to suppose that the Prime Minister would dissent from the action proposed by the Atomic Energy Authority in a letter received from its chairman. In that letter, of January 21, Sir Edwin Plowden said that the Authority endorsed and will follow the principles of organization laid down in the report of the Fleck Committee appointed to inquire into the organization of certain parts of the Authority, and it also accepts in general the scheme of organization recommended for the Industrial Group and expects, in large measure and over a period of time, to implement the Committee's recommendations. It will endeavour to approach as nearly as possible the organization visualized by the Committee, having regard to the individuals who hold or could be found to fill the senior posts. The Authority is already embarking on a programme of recruitment from outside and of transfer within its own organization. On January 27, Mr. Maudling, replying to a parallel question, said that the Government and the Authority are still considering the implementation of the recommendations of the report of the Fleck Committee which investigated the health and safety arrangements of the Authority.

In reply to a further question about nuclear power station contracts, Mr. Maudling said that besides the four consortia formed in the earlier stages of preparation for the nuclear programme and trained by the Atomic Energy Authority in collaboration with the Central Electricity Authority, a fifth consortium has since been formed and trained at its own request. For technical reasons the design and construction of a nuclear power station can best be undertaken at present by such groups of companies. No exclusive rights are granted to the use of the Authority's information. The system will be kept under review, and more conventional methods may be possible later.

Exchange of Information on Thermonuclear Fusion

A JOINT United States–United Kingdom conference to exchange classified information on research in the field of controlled thermonuclear reactions was held during February 3–5 at the Naval Research Laboratory in Washington, D.C. The exchange of information is under provisions of the agreement for co-operation on civil uses of atomic energy between the two countries. This is the sixth such meeting since the co-operative programme between the two nations was inaugurated in October 1956.

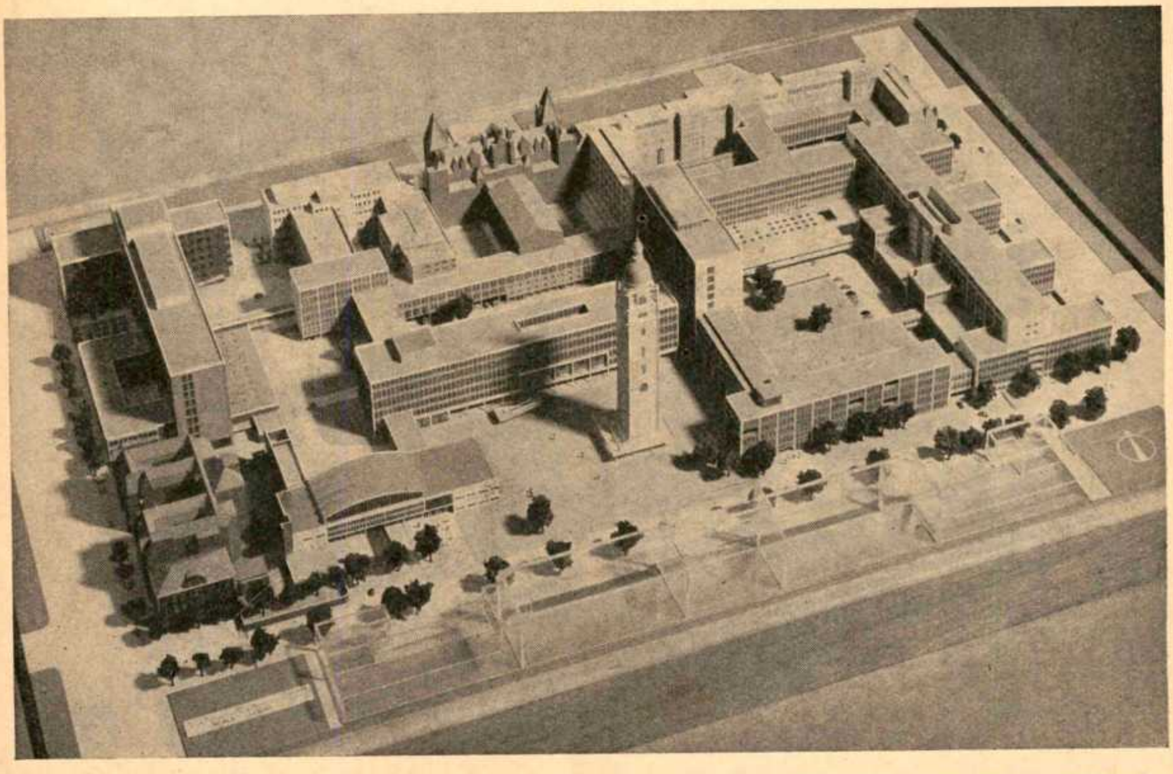
In the British delegation were: J. R. Bickerton and G. N. Harding, Atomic Energy Research Establishment, Harwell; R. F. Hemmings and B. S. Liley, Associated Electrical Industries, Aldermaston; H. Bodin, Atomic Weapons Research Establishment, Aldermaston. The United States were represented by teams of scientists led by A.E.C.-supported projects, including the Los Alamos Scientific Laboratory, Oak Ridge National Laboratory, Princeton University, the University of California Radiation Laboratory, New York University and the Naval Research Laboratory. Leaders of the groups attending were: Dr. James L. Tuck, Los Alamos Scientific Laboratory; Dr. E. D. Shipley, Oak Ridge National Laboratory; Dr. Lyman Spitzer, jun., Princeton University; Dr. Chester Van Atta, University of California Radiation Laboratory; Dr. H. Grad, New York University; Dr. W. R. Faust, Naval Research Laboratory.

Development of the Imperial College of Science and Technology

THE revised scheme for the development of the central site of the Imperial College of Science and Technology, London (see *Nature*, **177**, 723; 1956; and **178**, 123; 1956), in the rectangle bounded by Exhibition Road, Imperial Institute Road, Queen's Gate and Prince Consort Road, has now been placed before the London County Council for planning approval. The scheme retains the tower of the Imperial Institute Building, designed by Collcutt, as a central feature in the form of a free-standing campanile rising from the central court, in accordance with the recommendation of the Royal Fine Arts Commission. The Royal School of Mines building designed by Aston Webb, and the new building for the Departments of Chemical Engineering and Aeronautics designed by Norman and Dawbarn, have been incorporated into the scheme together with certain other buildings which do not form part of the College, notably the Royal School of Music on the northern side of the site. When completed, the new buildings will accommodate 3,000 students and will have a daily working population of more than 4,000 people. Work on the scheme, recently approved by the London County Council, for the development of Prince's Gardens, just off Exhibition Road, as halls of residence for the College is due to start this year. It will provide, in the first instance, residential accommodation for nearly 1,000 students. The plans embody a new conception of halls of residence, interpreting in contemporary terms the staircase system of the older universities.

Liberal Education in Technical Colleges

SOME useful suggestions about the place of liberal studies in technical education were made by Mr. A. A. Part, head of the Further Education Branch of the Ministry of Education, at King's College, Newcastle upon Tyne, on November 19. The education of a free man, he suggested, should be concerned with four



Model of the revised plan for the development of the Imperial College of Science and Technology: view from the south-west essential features. First would be the development of self-respect. Second would come the stimulation of independent thought, and thirdly, closely allied to it, the fostering of the spirit of enterprise and imagination. Fourthly, the free man, in the circumstances of to-day, when all activities are becoming increasingly complex, must be able to work as a member of a team. In addition, many people would consider that to be truly free, a man needs the support of religion; one of the greatest reforms of the Education Act of 1944 was to secure for every schoolchild the opportunity for religious worship and religious instruction in school.

Institute of Information Scientists

At a meeting held at the Institution of Electrical Engineers on January 23, which some 125 persons (mostly graduate information officers) attended, Dr. G. Malcolm Dyson took the chair, and opening speeches were made by Mr. J. Farradane (Tate and Lyle, Ltd.) and Mr. C. W. Hanson (British Scientific Instrument Research Association). The proposal "That a professional body be, and is hereby, set up to promote and maintain high standards in scientific and technical information work and to establish qualifications for those engaged in the profession" was carried. The new professional body has been named the Institute of Information Scientists, and a temporary working committee has been appointed to devise a constitution for approval by a later meeting, when the permanent officers will be elected. Further information about the Institute can be obtained from Mr. J. Farradane, "Torran", Crofton Road, Orpington, Kent.

International Instrument Show

The International Instrument Show will be held in Caxton Hall, London, during the last week of March, opening on March 24. It is expected that more than sixty factories from ten countries will be participating, and their products will include a number of the latest technical achievements in the fields of printed circuits, ultra-violet television microscopy, electron paramagnetic-resonance spectroscopy and telemetry. This year greater emphasis has been placed on the attendance of factory engineers. Normal day opening hours will be from 10.30 a.m. to 6.30 p.m., but to facilitate the attendance of parties of students and apprentices, the show will remain open until 9 p.m. on March 26 and also until 12 noon on the following Saturday morning. Admission is free to *bona fide* applicants. Tickets are available from the sponsors, B. and K. Laboratories, Ltd., 57 Union Street, London, S.E.1.

Humphry Davy Lectures

The London Section of the Royal Institute of Chemistry is sponsoring a new series of lectures, to be called the Humphry Davy Lectures. The first, entitled "Purity and Purification of Chemical Substances", will be given by Prof. Arne Tiselius (University of Uppsala) at the Royal Institution, 21 Albemarle Street, London, W.1, on February 19 at 6.30 p.m. The chair will be taken by the president of the Royal Institute of Chemistry, Prof. W. Wardlaw.

Dr. W. J. Jongmans

Prof. John Walton, of the University of Glasgow, writes: The obituary notice by Alan Wesley which appeared in *Nature* on January 18 gave an interesting account of the work of Dr. Jongmans, but it should also be recorded that Jongmans was largely responsible for organizing the very successful and memorable series of congresses on Carboniferous stratigraphy held at Heerlen in 1927, 1935 and 1951. The idea of holding such a Congress was the result of conversations between Jongmans, Prof. Armand Renier and Prof. Walther Gothan. Jongmans, however, was responsible for practically all the organization and the editing of the voluminous *Comptes Rendus*. The congresses brought together those interested in Carboniferous geology from many parts of the world and the delegates received much hospitality from the City of Heerlen and the State Mines. In 1938 the University of Glasgow conferred on Jongmans the honorary degree of LL.D.

Dose-Rate Effects in Radiation-induced Chemical Reactions

Referring to this article by Dr. H. C. Sutton and Prof. J. Rotblat (*Nature*, 180, 1332; 1957), Mr. J. P. Keene (Physics Research Department, Christie Hospital and Holt Radium Institute, Withington, Manchester 20) writes: "I have already published (*Rad. Res.*, 6, 424; 1957) an account of some measurements of G^{Fe} at 10^{10} rads/sec. The value obtained was 14·3, which is probably not significantly different from the value of 15·45 obtained by Schuler and Allen (*J. Chem. Phys.*, 24, 56; 1956) for dose-rates in the range 10^{2}–10^{6} rads/sec., and values in the region of 15 obtained by other workers at lower dose-rates. Thus we may conclude that most of the fall in the ratio $G^{\mathrm{Fe}}/G^{\mathrm{Ce}}$, due to electron irradiation in the range 10^{8}–10^{10} rads/sec. observed by Sutton and Rotblat was in fact due to an increase in G^{Ce}".

Announcements

Dr. G. E. R. Deacon, director of the National Institute of Oceanography since its foundation in 1949, has been elected a foreign member of the Swedish Royal Academy of Sciences.

Dr. Detlev W. Bronk, president of the U.S. National Academy of Sciences and also president of the Rockefeller Institute for Medical Research, has been awarded the Gold Medal of the International Benjamin Franklin Society.

A conference on "Fundamental Aspects of the Dehydration of Foodstuffs" will be held at the University of Aberdeen during March 25–27. Further information can be obtained from the Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

The Institution of Electrical Engineers Faraday Lecture for 1957–58 will be given at the Central Hall, Westminster, at 6 p.m. on February 12. The subject will be "The Electrification of Railways". The Lecture was prepared by the late Mr. G. H. Fletcher and will be delivered by Mr. R. Ledger. Admission is free, by ticket obtainable from the Institution of Electrical Engineers, Savoy Place, London, W.C.2.

The title of the book by L. Saunders and R. Fleming noticed in *Nature* of January 18, p. 147, was given incorrectly: it should read "Mathematics and Statistics for Use in Pharmacy, Biology and Chemistry".

FLOW NOISE

DURING the latter part of the last century, the great scientists who studied acoustics attacked and solved most of the problems of acoustic excitation and propagation, the one notable exception being that of sound created by moving air. Since that time, partly because of its relative unimportance, but chiefly because of its intractability, the acoustician has only tackled the problem in a physical manner to explain the discrete frequencies which occur when air blows over wires (aeolian tones) or on to a sharp edge (edge tones) and has not at any time appealed to mathematics to obtain quantitative solutions. Since the Second World War, the greatly increased power used in civil airliners, made possible by the invention of the jet engine, has brought forth a noise situation in which the enormous power developed has more than outweighed the inefficiency of conversion of kinetic energy and has precipitated a major conflict between the flying and non-flying public. A detailed study of jet noise has thus become urgent, and this has brought into the field of acoustics those scientists who have, by tradition, been most knowledgeable about the details of the source, namely, the fluctuating flow in the jet as it mixes with the surrounding air. Since the acoustic output of a typical jet engine consists of only one-hundredth of 1 per cent of the total engine-power, this has involved a highly mathematical treatment. Hence, in Britain, the acoustician with his physical interpretation and the aerodynamicist with his mathematical approach have tended to keep apart, even while dealing with the same problem.

Thus it was that, at the joint meeting of the Acoustics Group of the Physical Society and the North-eastern Branch of the Institute of Physics held in Newcastle upon Tyne during November 15–16 under the joint chairmanship of Prof. E. G. Richardson and Dr. O. P. T. Kantorowicz, the major outcome was the cross-fertilization of ideas arising from these two groups. Indeed, as Prof. E. J. Richards (Southampton) pointed out in his introductory address, noise suppression has now become a study of turbulent mixing and has moved some way from pure acoustics. Thus, whereas the two-day conference was split into sessions on noise in air and in water, respectively, the natural gulf was, in fact, that between papers on turbulence and on discrete-frequency sound.

In the first category, considerable interest was aroused by three papers concerned not with noise and its propagation but with the aerodynamics of jet flow. In his talk, Dr. G. M. Lilley (Cranfield) examined the terms of Lighthill's equations and from them put forward valuable ideas regarding the essential parameters on which jet noise is based. He also examined in more detail than in the past the nature of the turbulence of the stream and its significance in contributing to the quadrupole sources of sound. Probably his most interesting proposal concerned a suggestion recently made by Townsend, that eddies emanating from a jet can be likened to long vortices stretching downstream with their axes along the line of the jet. He speculated that since these supply the major energy-carrying eddies, they are probably the greatest sources of sound; the obvious corollary to this is, of course, that noise-suppression techniques should be based on the deliberate destruction of these toroidal vortices, presumably by cross-flows and quick mixing systems.

In this category of papers on turbulence and its relationship to noise were also two papers from the United States: Dr. R. H. Kraichnan, of the University of New York, talked about the pressure and sound fields of turbulence with high Reynolds number, while Dr. E. Skudryzk, of Pennsylvania State University, presented some most interesting results regarding the noise produced by the boundary-layer turbulence of a rotating cylinder. Undoubtedly these three papers, involving the relationship between wide-spectrum noise and turbulence, indicate the direction of future flow-noise researches at least for the next five years.

The other papers presented in this two-day conference dealt almost exclusively with discrete-frequency sound phenomena. Such phenomena are, of course, much easier to picture physically and were received with considerable interest by the less mathematical members of the conference. Edge tones in water were described by Mr. M. Gross (Newcastle). Dr. J. H. Gerrard (Manchester) described his experiments on the singing of wires (aeolian tones); the hydrodynamic oscillator was described by Dr. G. G. Parfitt (Imperial College of Science and Technology, London) and the effect of nicking on organ flue pipes by Dr. D. M. A. Mercer (Southampton). It is impossible in the space available to describe these interesting contributions, nor the general survey by Mr. M. P. Tulin of the water-noise researches being carried out in the U.S. Naval Research Laboratories, in any detail. Dr. Parfitt's description of the work at Harvard in developing a hydrodynamic oscillator which provides a sound level of 165 decibels in air for the expenditure of only 14 watts in energy shows how noise and pressure resonances, normally a nuisance, can also be harnessed to provide a very efficient means of energy-transfer.

As would be expected in the study of sound by aerodynamicists, optical schlieren techniques have become the accepted method of studying discrete-frequency phenomena. One of these phenomena arises from the sound which is given out when an eddy passes through a shock wave. Since this sound

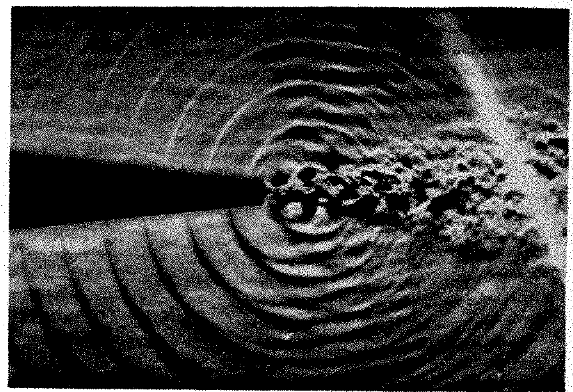


Fig. 1

wave proceeds upstream and produces a fluctuating flow, it is easy to see that for some frequency a self-sustaining system or resonance will occur. Two somewhat similar papers on this subject were presented at the conference, one by Mlle. Merle (Marseilles) and Mr. M. G. Davies (Liverpool). Both authors described their work on the 'back reaction' or resonance mechanism, Mlle. Merle showing a most interesting film of the cellular pattern in the jet. Mr. Davies gave more attention to the geometry of the system and a method of prediction of the frequency. The standard of photography was excellent in both cases; a typical photograph by Mr. Davies showing the sound waves emanating from the choked jet stream is shown in Fig. 1.

During the conference, members were conducted around the laboratories of the Pametrada Research Station and the cavitation tunnel at King's College, Newcastle. It is to be hoped that this meeting will be only one of a series drawing together workers in acoustics and aerodynamics, separated as they are now by the wide gulf of tradition.

ENZYME CHEMISTRY

An international symposium on enzyme chemistry organized by the Science Council of Japan was held under the auspices of the International Union of Biochemistry in Tokyo and Kyoto during October 15–23. The president of the symposium was Dr. Seiji Kaya, president of the Science Council of Japan, and Dr. Keizo Kodama was chairman of the organizing committee. The meeting was reported to be the largest international gathering of scientists held in Japan since the War, 108 non-Japanese from twenty-one countries and 816 Japanese being present. The attendance from Western European countries was regrettably small, about half the overseas visitors being from North America, eight from the Soviet Union and numbers of from one to four from other countries. The thoughtfulness of the Japanese in presenting their work for the most part in English went a long way towards overcoming the language barrier, and their friendliness and the very great care with which our Japanese hosts had evidently planned every detail of the excellent organization made for an exceptionally smooth-running conference. Both at the University Club at Tokyo and within the University buildings at Kyoto, large and well-equipped reception and meeting rooms were provided. All participants received on arrival a massive volume containing the text of some 150 communications; the printed proceedings are to be published later and will include the discussions which followed the presentation of these papers.

Special lectures were given by Britton Chance on cytochromes in living cells, by H. Tamiya on the koji as a source of enzymes in Japan, by W. A. Engelhardt on enzymology and mechanochemistry, and by F. Lynen on the phosphate cycle and the Pasteur effect. H. Theorell and F. Lipmann, who were to have delivered conference lectures, were, unfortunately, unable to attend.

The proceedings were grouped under four main topics: mechanism of enzymic group transfer; enzyme systems of hydrogen, oxygen and electron transfer; formation of proteins and enzymes; enzymes and industry.

It would be impossible to mention here more than a few of the individual contributions, most of which maintained a high scientific level. The enzymic synthesis of polynucleotides was described in papers by A. Kornberg and S. Ochoa; lipoic acid and its functions in keto-acid metabolism by L. J. Reed and I. C. Gunsalus; pyridoxal-catalysed enzymic metabolism of amino-acids by E. E. Snell, A. E. Braunstein and K. Ichihara and their colleagues. Japanese work on cytochromes was reported by K. Okunuki, M. Ishimoto and S. Minakami, among others. A striking feature of the exhibition held in connexion with the symposium was the display of crystalline cytochromes by Japanese workers. In the same exhibition was a surprising range of crystalline proteolytic and other enzymes, of which some were commercially available, large samples being generously presented to visitors. Japanese work of industrial importance on the fermentative production of adrenaline and glutamic acid was presented at the scientific meetings.

Further papers concerned oxidative phosphorylations, to which subject outstanding papers were contributed by D. E. Green, B. Chance, A. L. Lehninger and E. C. Slater; while various other aspects of phosphoryl group transfer were described by A. H. Ennor, H. Tamiya and O. Hoffmann-Ostenhof. Biosynthesis of peptide bonds in relation to cell-structure was described by N. M. Sissakian and by T. Peters, and W. E. Knox gave a valuable account of adaptive enzyme formation in animals. The three members from the United Kingdom (F. Dickens, M. R. Pollock and C. Rimington) also presented papers.

At the closing session, Prof. A. Akabori, chairman of the Executive Committee, to whom must go much of the credit for a splendid job of organization, summed up the events of the symposium, and Prof. M. Florkin as president of the International Union of Biochemistry eloquently put the appreciation of the Union. The thanks of non-Japanese members were expressed by Prof. A. K. Balls who, on their behalf, presented to Prof. Kodama an illuminated scroll containing the signatures of the overseas members together with a brief message of appreciation in Japanese, offering their thanks and congratulations on a remarkably valuable and enjoyable symposium.

A full and varied programme of social events was provided, including a number of receptions, displays of Japanese dancing, the tea-ceremony and other picturesque traditional Japanese customs. Many overseas visitors were also able to enjoy the unique experience of life in a ryokan, or Japanese-style hotel, a charming and restful contrast with the bustle and noise of modern Tokyo.

Very attractive glimpses of the beautiful Japanese countryside were provided by excellent rail and bus excursions to the National Park at Nikko, to the ancient city of Nara and to the extremely interesting pearl-fisheries at Kashikojima.

After the symposium, three short further meetings were held. In Kyoto, Prof. Yas Kuno presided over a first-class two-day conference on water-soluble vitamins, organized by the Vitamin B Committee of Japan, which was attended by about fifty people. This is, of course, a field of intense Japanese activity, and some good Japanese papers were presented.

In Osaka, a one-day meeting on starch and amylases was held under the chairmanship of Dr. Shiro Akabori. At another informal but valuable discussion, on "The Metabolism of Cyclic and Sulphur Amino-acids", also held at Osaka on October 26, the contributors included A. Braunstein, [the late] C. Fromageot, W. E. Knox and K. Ichihara. All three of these meetings served to confirm the strong impression already formed by the visitors of the great energy and numerical strength of biochemists in Japan, and of their often outstanding technical ability which enabled them triumphantly to surmount the rather widespread difficulties due to old equipment and laboratories, many of which were not really adequate as judged by current European and American standards. In spite of these handicaps, to which must be added the low salaries of academic workers and the difficulty experienced by younger scientists in obtaining suitable posts at home and, still more, grants for travel abroad, the visitor could scarcely fail to be filled with admiration on observing the tenacity with which the Japanese workers pursued their researches, undaunted by these somewhat formidable difficulties. I am grateful to my two English colleagues at the symposium for their comments on this necessarily incomplete report. On the whole, this was a most rewarding symposium and a unique experience for most Western visitors.

F. DICKENS

RESTORATION OF AGRICULTURAL AND OTHER SOILS

ONE of the problems in connexion with the restoration of soil that has suffered a major disturbance is the length of time which elapses before full fertility can be restored. Two papers dealing with aspects of this problem were read at a meeting of the Association of Applied Biologists in Leeds on September 19. The first of these was by R. Holliday and D. R. Hodgson on "Restoration of Land covered by Pulverized Fuel Ash". This paper dealt with investigations in progress at the University of Leeds under a research grant from the Central Electricity Authority, which is the main producer of fuel ash of this type.

The ash occurs in lagoons, into which it is washed after separation from the spent gases with which it is discharged. Utilization or disposal of this deposit after the lagoons are full is a major problem; its use for filling quarries involves costly transport, and wide-scale industrial use appears unlikely. Possible agricultural uses are therefore under investigation.

The agronomic problem posed is one of growing plants in material with the following properties: it consists mainly of spherical particles between 0·2 and 0·002 mm. in diameter, chiefly silica but with various metals incorporated; normal soil structure is lacking; it sets hard when dry but can be eroded by wind unless sealed with soil; the *p*H is high, varying between 8·5 and 10·5; it is deficient in plant nutrients and contains toxic ingredients; microbiologically it is completely sterile.

The problem of making it suitable for crop growth at a low cost is being investigated along these lines: reclamation through the use of a soil cover and fertilizer application; amending the ash as a growing medium by making up nutrient deficiencies, correcting toxicities and improving the structure; selection of crop plants tolerant to the adverse conditions.

Results are now available on soil cover trials using depths of up to 2 ft. of subsoil and 1 ft. of surface soil with four different surface concentrations of complete fertilizer. The crop-yield was affected with cover depths of less than 2 ft. of soil plus subsoil, but little beyond this level. The highest yields were obtained with a deep soil cover and a high fertilizer rate. Moderately good yields were obtained, however, from either a deep soil with moderate fertilizer rate or a shallow soil covering with a high fertilizer rate. Soil is often a scarce commodity and transport is costly, therefore the second alternative is more economical. All rates of fertilizer application gave poor results where no soil cover was used. The material was found to be deficient in nitrogen and phosphate, but potash is generally adequate.

Different crop plants have shown marked variation in the degree of root tolerance to the ash, but it is not clear whether this is a toxicity tolerance or a reaction to the physical structure of the growing medium.

Various methods to reduce alkalinity have been tried, in most cases with beneficial results. The question of cost, however, rules them out for large-scale use.

Dilution of the ash by the addition of bulky materials, including neutral and acid organic materials, shales and sewage sludge has given promising results in some cases.

Field trials on the capacity of various crops to grow in the ash have shown some plants of the orders Chenopodiaceae, Cruciferae and Leguminosae to be reasonably tolerant to the adverse growing conditions. Other crucifers and grasses have intermediate tolerance, while a wide range of economic plants, including cereals and pulse crops, are exceedingly sensitive. It has been shown that a period of weathering makes the growing conditions less unfavourable, and allows more of these plants to be grown with reasonable success on the ash.

The second paper, on "Some Biological Aspects of Opencast Coal Working", by H. W. Thompson, dealt with changes which occur in surface soil during opencast operations, resulting in lowered fertility and other undesirable qualities which persist for some years. Many factors are involved, some of which follow upon changes in the fauna of the soil.

Biological problems may arise in various ways. Many restored sites suffer from wetness, because permanent drains destroyed by opencast mining cannot be replaced until soil settling has ceased. Crops grown on undrained land frequently lack vigour and so are more liable to suffer pest injury, particularly by such pests as leather-jackets or slugs. Similarly, frit fly attack has often ruined spring oat-crops which, because of adverse soil conditions, have been slow in establishment, with poor capacity for producing tillers.

Serious loss of crops arising in this way can often be avoided by care in cropping or, where appropriate, by the use of insecticides. The wetness problem may be solved in some cases by mole draining until such time as permanent drains can be replaced.

A different type of problem occasionally arises through the introduction of harmful organisms to an area not previously affected. There is an obvious risk, for example, of cyst-forming eelworms being spread when infested and non-infested soils are stored together and later distributed. Cysts of some of these eelworms can survive for twelve years or more in the soil. This aspect is therefore being studied, particularly in the case of the potato root eelworm.

This problem is not common at opencast sites, but has arisen in Lancashire where opencasting is in progress in an intensive arable area. Potatoes are an important crop and fields free from infestation are therefore particularly valuable. The spread of infestation is being studied at one such site. Samples of all fields to be worked were taken before scraping commenced. These showed some fields to be free from measurable infestation while others yielded high cyst counts. These fields will be re-sampled after restoration has been completed.

It was thought possible that cyst viability falls off more rapidly under spoil heap conditions than it would normally in arable land, especially where storage continues for several years in large heaps. At one site there was a definite indication that this does occur. Hatching tests on cysts collected from the top foot of soil showed moderate viability; samples from 8 ft. depth yielded cysts of very low viability, and those from 3 ft. depth showed intermediate larval emergence. The evidence so far from this, and from other sites where soil from heavily infested fields was stored, shows that the risk of spreading serious eelworm trouble as a result of opencasting is not very great, especially in view of the long rest from potato growing which is involved.

Another factor which is regarded as very important in its effect on soil structure and fertility is the great reduction in numbers of earthworms brought about by opencast working. Work on this aspect was therefore started in 1956. The object is to study the number of earthworms during the operation itself and to continue to do so after restoration until fertility is restored or the earthworm population has reached stability. Earthworm collection is carried out by hand digging because of the unusual conditions prevailing in spoil heaps.

A site near Wigan is being used, the soil being a sandy loam with an earthworm population estimated at 609,800 per acre before stripping commenced in May 1956. Counts on two spoil heaps and on an unworked area alongside have been made at roughly monthly intervals since. One spoil heap with a surface area of 1·2 acres is made up of surface soil from 11 acres, and the second, of 0·61 acres, from 4·8 acres.

Estimates made in August—four months after heaping—showed a low survival of earthworms, but by the following March numbers had increased to an estimated 77,000 in heap 1, and 43,000 in heap 2. Apart from a fall during the hot, dry period in June, numbers have remained at a relatively high level since, the highest estimates in both heaps and in the control area being obtained in March and October. A more complete picture of earthworm survival will be available after restoration has been carried out.

The opportunity was taken to study the earthworm position at a Barnsley site restored in 1952 after opencasting and cropped since then under twelve experimental rotations. Counts made in 1956, that is, four years after soil replacement, indicated that an earthworm population that could be regarded as normal for this type of soil had become re-established. The highest estimates were obtained from grazed leys with a population of 315,800 worms per acre, and nine of the twelve series of plots had counts exceeding 150,000 per acre. The information obtained from this site therefore suggests that re-establishment of earthworms after opencasting can be much more rapid than is generally believed to be the case.

THE SCIENCE MASTERS' ASSOCIATION

ANNUAL MEETING

THE annual meeting of the Science Masters' Association, which was held during December 31, 1957–January 3, 1958, in the University of Leeds, was attended by more than five hundred science masters. Among those who came into residence in the University Halls were masters and students from Canada, South Africa, and Tasmania; the Royal Navy also sent its usual numbers from naval educational establishments.

The first evening began with the Association dinner, at which the toast of the Association was proposed by Prof. F. S. Dainton, chairman of the University School of Chemistry; this was responded to by the chairman of the Association, Mr. W. G. Rhodes, education and training officer of Arthur Lee and Sons, Ltd., steelmakers, of Sheffield. The members then assembled in the Parkinson Hall, where the presidential address was given by Sir Charles Morris, vice-chancellor of the University of Leeds.

Sir Charles was concerned with the fact that the external examinations undergone by schoolboys tend to be a test of the schoolmaster rather than of the pupils; a good master can cause indifferent pupils to pass; and he wondered whether science is not being taught too well. He thought also that too many facts are being taught, and that it is more essential to teach fundamental principles: as a philosopher, he thought that over-reliance on the memory is a very grave fault. This over-reliance is due largely to the great mass of facts which modern pupils are expected to assimilate: it is high time that dons and schoolmasters came together to reduce the content of the syllabuses. Sir Charles then dealt with the problem of what science should be taught to those who will not become professional scientists. Whereas the training in arts needed by the scientist is comparatively easily met by giving him a broad education in the use of language and the appreciation of literature, it is not so easy to determine the solution of the converse problem. It is not sufficient to let the non-scientist do badly some diluted version of the scientist's course; what is needed, it seemed to Sir Charles, is the philosophical approach, whereby the great steps in the history of science, the modern applications of science, and its future possibilities are all freely discussed. He thought that science teachers tend to like to teach what they know with certainty, and that they are "deeply unwilling to go outside the field of precise knowledge". It is most important that the misunderstandings between scientists and humanists should be recognized as a deep and serious problem of education; it is something that we had even begun to think about it.

The mornings of the three succeeding days were occupied by lectures. These were by Prof. J. G. Wilson on cosmic ray astronomy, by Prof. L. N. Pyrah on scientific methods in urological research, Prof. F. W. Spiers on "Radiation and Man", Prof. J. T. Whetton on science applied to mining problems, Prof. E. A. Spaul on hormones and behaviour, Prof. E. G. Cox on magnetism and chemistry, Dr. F. E. Hoare on low temperatures as a research tool, Dr. Dorothy H. Rayner on problems of palæontology and evolution, Prof. R. D. Preston on physics applied to botanical problems, and Prof. J. B. Speakman on the chemical revolution in textile technology. Guest lecturers from outside the University were Mr. A. B. Thompson, of the Imperial Chemical Industries Terylene Council, who dealt with the physico-chemical principles underlying fibre-making processes, and Prof. L. Rosenfeld, of the University of Manchester, who spoke on Hellenistic science; the growth of interest in the history of science was shown by the size and membership of his audience.

The second evening-lecture, held under the auspices of the Science and Civilization Lecture Fund, was given in the Parkinson Hall by Mr. Ritchie Calder, who spoke on "The Presentation of Science to the Public". Mr. Calder dealt first with his own experiences in Israel when he was engaged in making plain to the Israeli public that a costly research institution was an asset to the State, even at a time when the State was fighting for its existence, and when the value of the scientific work undertaken might not have been immediately obvious. He found that the research scientists themselves are all too apt to think that any indulgence in publicity would lead to a lowering of their scientific standards. He went on to give other instances, not in Israel, where famous scientists had to be persuaded that it was very well worth while to give accounts of their work which could be understood by the ordinary newspaper reader.

The afternoons were occupied by visits to university departments and to factories and other works near Leeds; there were twenty-four of these, a record number. On the third evening the University held a reception for the Association; at this some three hundred members and their ladies were welcomed by the Chancellor, H.R.H. The Princess Royal.

An exhibition by publishers, manufacturers, and members occupied a large space in the chemical and physical laboratories; there were also special exhibitions by the Atomic Energy Research Establishment, the Aluminium Development Association, and the Copper Development Association.

A programme of scientific films, rather larger than usual, included one entitled "Galileo's Law of Falling Bodies", made by Encyclopædia Britannica Films, Ltd., in the United States in conjunction with the Ford Foundation; this forms part of a filmed teaching course of physics, which will be obtainable in Britain from the Gaumont British Film Library.

The final morning session ended with a demonstration and a discussion, which, owing to limitations of time, had to be held simultaneously.

The very striking demonstration, entitled "Biology for Non-Biologists", was given by Mr. C. H. Bailey, senior lecturer in science at Didsbury Training College; his experiments were carried out with simple apparatus and are intended for those teaching in secondary modern schools, where only a minimum of equipment may be available.

The discussion was held by the Association's Science and Religion Group, and was initiated by the Rev. G. W. Burningham, who acts as chaplain to the Anglican students at the University of Leeds. He emphasized how much greater was the interest of students in religion than it was twenty years ago, and that, if anything, the science students were more keen than the others; there is now more realization of the interdependence of scientific discoveries and religious beliefs. The ensuing discussion ranged over such subjects as miracles, the nature of the soul, and definitions of Heaven and of eternal life.

At the business meeting, Sir Lawrence Bragg was elected president for the ensuing year, and Mr. Charles Holt, of Harrow Weald County School, was elected chairman. The treasurer, Mr. S. W. Read, reported a very favourable balance on the year's working; and it was announced that the next meeting would take place in University College, London, during December 30, 1958–January 2, 1959.

THE METEOROLOGICAL OFFICE

ANNUAL REPORT, 1956–57

SOME years ago a prominent authority was heard to suggest that the annual report of the Meteorological Office might well provide a splendid subject for discussion at a meeting of the Royal Meteorological Society; for every year it gives food for thought. Englishmen regard the weather as their common property; and informed scientists cannot but admire the determination with which the public service endeavours to remain free from perturbation, whatever difficulties attend their efforts to cope with the vagaries of atmospheric behaviour. The Meteorological Office, in the nature of things, is always on guard duty. Day by day its actions, like those of the sentries at Buckingham Palace, are subject to every variety of comment from the bystanders. Fortunately there are always some with enough knowledge to admire a difficult task well done; and to recognize that the demands of a modern community continue to add to the difficulties. Forecasting the winds for a jet bomber at 50,000 ft. is a requirement far beyond the conceptions of those who, sixty years ago, were willing to estimate in what parts of the country the term 'muggy' might apply, on the assumption that the oncoming depression would resemble Abercromby's classical model.

The annual report of the Meteorological Office for the year ended March 31, 1957*, shows admirably, with a subdued but unmistakable note of confidence, that the public service continues to make that sober progress which is to be desired on the part of those who study turbulent motion. As Sir Graham Sutton says, the meteorological problem is probably the most difficult in classical physics, and progress can only be made with the utmost diligence. Forecasting naturally attracts most attention; and efficient accomplishment in dealing with stupendous quantities of incoming factual material will be greatly aided as newly installed electronic computers come more into use. The development and direction of an active cadre of young research workers will ensure that in an accelerating world we shall not only keep up with our neighbours, but may here and there set the pace.

Readers of the report cannot fail to be impressed by the variety of services provided and by the diversity of research; for example, "experiments with the release of silver iodide from ground generators on Salisbury Plain continue with no result yet detectable". Elsewhere is mentioned the work on forecasting the outlook for periods up to a month ahead; "the outlook on this stubborn problem is rather brighter than hitherto".

The British business man is too often insufficiently aware of these public services; and the potential rewards of successful forecasting offer abundant temptation to incautious consultants. There are those who, to all appearance, gamble on sunspots; those who believe it has been given to them to discover periodicities of various sorts; those who think in terms of singularities, and perhaps some on the outskirts who appear to be best described as 'hunch-drunk', to use the delightful phrase coined by an eminent professional meteorologist. But how many of our would-be 'independent consultants' have the temerity to disregard the world synoptic charts, so efficiently assembled by the Meteorological Office working with other nations in an unostentatious but exhilarating daily display of international collaboration?

RÉAUMUR

BESIDES his thermometer, René-Antoine Ferchault, lord of the manor of Réaumur in the Vendée, and of Des Angles and La Bermondière, made many contributions to scientific knowledge. In 1708, at the age of twenty-five, he presented a memoir to the Academy of Sciences, and in 1709 two others concerned with general solutions of certain geometrical problems. Having justified his election as *élève* in geometry, he then turned his attention to natural history, and in some highly original observations demonstrated that the shells of molluscs grow by successive external additions of new parts rather than by the alternative process of intussusception. On the death of the geometer Louis Carré in 1711, he was promoted to *pensionnaire mécanicien* and put in charge of the work on trades, arts and crafts; he compiled volumes on the manufacture of anchors, of pins and of cast iron.

In the next few years Réaumur discovered an insect living as an internal parasite on the snail; he studied the movements of shell-fish, sea-anemones and starfish, and the great variety of organs of locomotion in shell-fish and their means of attachment to different solid bodies; he found a hitherto unknown fish that gave a purple colouring matter like the famous Tyrian purple of the ancient world; he demonstrated the correctness of the popular belief that crayfish, crabs and lobsters, having lost a claw, could grow another in its place; he studied the torpedo fish, or electric ray, known for its property of benumbing the hand or limb that touched it, and, while the usual explanation was that this was due to the emission of 'torporific corpuscles', he argued that it was produced by the speed and rapidity of the blow that the ray could inflict by means of its admirably constructed muscular system; he examined the native turquoises of Languedoc, showed that they were in no way inferior to those imported from Persia, supposed at that time to be the only source of these gems, and demonstrated by experiments that they were petrified fossil-bones coloured by a metallic ingredient dissolved in them by firing; he studied pearls and their production and falsification, considering the former as due to disease and showing that the colouring matter of false pearls was obtained from the scales of a fish known as the ablette (in English, the bleak); he examined the great bank of *falun*, or fossil shell-marl, in Touraine; he was interested in the nature and formation of flint, in the plant called *Nostoc* or star-jelly, in the luminescence of certain shell-fish, in the ease of magnetization of iron and steel by percussion, and in the recovery of gold from the sands of various French rivers; he had also already begun to reveal his active interest in the practical arts and their relation to the sciences, reporting to the Academy descriptions of the preparation of slate, and of the gilding of leather, of mining for iron-ore, of the manufacture of mirrors, of the drawing of gold-wire and the properties of paper and other bodies in preventing the passage of air and water.

Later, Réaumur published a paper describing the procedure for the conversion of wrought iron into steel: this is a landmark in the history of the iron and steel industry and effectively marked the introduction of the manufacture of steel into France.

Réaumur also rendered a similar service to the tinplate industry; he showed that vinegar was the cheapest and most effective solvent for the removal of the scale from the surface of the iron before tinning.

All this, as well as Réaumur's outstanding achievements with thermometers and in entomology, is described in a fascinating article by Prof. D. McKie published in *Science Progress* (45, No. 180; 1957). Besides this study of Réaumur, the journal contains an article by Prof. W. B. R. King on water supply and geology and one by Dr. G. H. A. Cole on the Earth and its magnetic field.

ORIGIN OF COMETS

"THE Distribution of the Directions of Perihelia of Long-Period Comets" is the title of a paper by J. G. Tyror in *Mon. Not. Roy. Astro. Soc.* (**117**, 4; 1957), in which he deals specially with Lyttleton's theory of the origin of comets (see *ibid.*, **103**, 465; 1948; and "The Comets and their Origin", Cambridge, 1953). This theory envisaged a process of accretion of dust particles by the Sun as it passed through interstellar dust clouds, and while it explained some of the observed features of comets and of their orbits, like many other theories it presented certain difficulties. If the theory is accepted, then comets must originally have come from preferred positions in the sky, and although the diffusion of the perihelion points of such a family would probably occur, it is considered that some traces of perihelion groupings, at least for families born during recent cloud passages, could be detected.

Mr. Tyror examines the distribution of perihelion points of long-period comets with the object of determining whether there is any evidence of such grouping. Previous investigations by W. H. Pickering and others suggested that there was some evidence of the grouping of aphelion points, but it has been considered advisable to revise these results in the light of additional information which has appeared since the completion of their work. The present survey does not include short-period comets and periodic comets because planetary perturbations would have eradicated reliable evidence of any original grouping; while it is true that all orbits would have been affected to some extent, the investigation has been carried out only for comets suffering slight perturbations. The whole subject is beset with difficulties because it is inevitable that available data must suffer to some extent from observational selection. A detailed description of the contents of the paper is quite impossible in a short note, and it will suffice to deal with the data utilized and the conclusions that have been reached.

Investigations of the positions of 448 comets with periods greater than 200 years were made, and of these 67 had calculated eccentricities greater than 1, 263 equal to 1, and 118 less than 1. There is evidence that the perihelion points of long-period comets tend to be distributed non-randomly, and it is pointed out that this tendency may be due to observational selection or to a real grouping phenomenon, or even to a combination of both. The first of these has undoubtedly played a prominent part in the discovery of comets, and other vitiating factors in the analysis are mentioned. The conclusions are summarized at the end of the paper and are briefly as follows.

The departure from randomness in the observed distribution of perihelion points of the comets considered is strongly suggested, and there is evidence indicating a preference for the perihelion points to lie near a particular great plane. In addition, the centre of the observed distribution appears to be significantly displaced towards a point on the celestial sphere. The identification of the plane with the plane of the Galaxy and of the point as that lying in a direction opposed to that of the Sun's motion cannot be considered unreasonable. These suggestions may be interpreted in the light of Lyttleton's accretion hypothesis, according to which the perihelion positions of comets should show a tendency to lie near the apex of the Sun's motion relative to the local interstellar cloud, and further, the distribution of perihelion points would have a preference for lying near the galactic plane.

QUALITY IN MEAT

NOW that the supply of meat is approaching the level of demand, quality is again assuming economic importance. Definitions and tests of quality have been examined by D. M. Joubert of the Department of Animal Husbandry, University of Pretoria, who has also examined the economic consequences which follow from changed attitudes towards quality (*Colonial Plant and Animal Products*, 6, No. 2; 1956).

Only a few decades ago quality in beef meant well-marbled meat covered by a thick layer of fat. Not only did the average consumer during those times demand more fat owing to the bodily needs imposed by hard manual labour, but also excess fat was used for other purposes, chiefly cooking. At present, cooking fats can be obtained from cheaper sources, the consumers perform less manual labour and are better protected in their homes against cold conditions, and consequently demand the minimum of fat with their beef. Since butchers are concentrating on carcasses of young animals, it is not unlikely that the optimum carcass weight will become even lower in future.

When considering quality in the case of mutton and lamb, the size factor is of primary importance. With the size of the average family decreasing all over the world and with cooking facilities less spacious than they used to be, the general demand is for small joints. Preference is given to a whole joint of small size over half a large one since the latter, because of its cut surface, does not retain its succulence so well and leads to greater wastage through exudation. As in beef, a minimum of fat is preferred. With the rapid development of the dairy industry in recent years and with progress in the manufacture of margarine, the excess fat is no longer widely used as a substitute for butter and goes to waste.

Definition of quality in mutton is particularly complicated because of the differences in the taste of individuals in respect of flavour. Mutton produced from early-maturing sheep (as, for example, Southdown, Suffolk) raised and fattened in stalls may appear extremely attractive and, therefore, be labelled as of high quality. On the other hand, mutton produced from late-maturing sheep breeds (such as Scotch Blackface, and even possibly Merino) off extensive pastures may, by comparison, appear unattractive and may be labelled as being of low quality.

The quality of pork is determined primarily by the amount and nature of the subcutaneous back fat. The amount of fat preferred with pork by consumers in Britain at present is considerably less than a few decades ago, while in South Africa, for example, a large amount of fat has never been tolerated except where it was required for purposes other than eating. It was not realized that lean pork can be produced provided the right type of animal is used and that correct feeding is practised, and the consumption of pork in South Africa remained extremely low until quite recently. On the contrary, in certain Continental countries the general taste demands rather more fat with pork, and a certain amount of excess fat is required by butchers for the production of a great many varieties of sausage and salami. Consequently the type of pig raised in the central European States (such as Germany and Hungary) differs markedly in its conformation from that which is considered as the ideal type in Great Britain and South Africa.

The final factors determining the quality of a piece of meat, and one which often nullifies all factors considered prior to its cooking, centre around the purely human element, namely, the ability of the cook—either to spoil the good qualities of meat through inefficiency, or to improve to such an extent the quality of a poor sample of meat through skill and knowledge of cooking, *per se*, that its pre-cooked quality remains unquestioned.

ASSAY OF VITAMIN A OILS

By Prof. E. BRUNIUS

National Institute of Public Health, Tomteboda, Sweden

IN 1954 a Vitamin Assay Commission was set up by the Food Division of the Applied Chemistry Section of the International Union of Pure and Applied Chemistry.

The official members of the Vitamin Assay Commission are: Prof. E. Brunius (Sweden, chairman), Dr. W. F. J. Cuthbertson (Great Britain), Dr. M. Kofler (Switzerland), Dr. B. L. Oser (United States) and Prof. H. Simonnet (France). The Commission has held four Conferences: in London 1954, Zurich 1955, Amsterdam 1956, and Paris 1957. In all the Conferences, besides members of the commission, the following participated: Dr. D. W. Kent-Jones (Great Britain, honorary secretary of the Food Division), Prof. R. Nicolaysen (Norway, member of the Food Division), Mr. E. Hayes (Great Britain), and Mr. R. J. Taylor (Great Britain). In addition the following were present at the Amsterdam conference: Dr. J. Straub (The Netherlands, member of the Food Division), and Dr. C. Engel (The Netherlands); and at the Paris Conference: Dr. K. Dürrenmatt (Switzerland, chairman of the Food Division), Prof. J. Brüggemann (Germany), Dr. C. Engel (The Netherlands), Dr. A. François (France), and Dr. J. Tiews (Germany).

One of the Commission's tasks was to develop a standardized method for the assay of vitamin A oils which would be acceptable in international trade.

Current vitamin A assay methods are based on the recommendations made by the Subcommittee on Fat-Soluble Vitamins of the World Health Organization. In its report[1] the International Unit of vitamin A potency is defined in terms of the activity of crystalline all-*trans* vitamin A acetate, and the conditions for the spectrophotometric assay of the vitamin are broadly set down. The elaboration of methods in different countries, however, has led to divergences in the assessment of vitamin A potency, and this has given rise to difficulties in the international trade in vitamin A oils. It was therefore considered an urgent task for the Commission to attempt to develop a standardized method of assay.

Vitamin A oils vary widely in quality and potency. At the outset the Commission decided, on the evidence available, to consider them in two categories according as their spectrophotometric characteristics approached those of pure vitamin A or not. For oils in the first category (comprising most fish-liver oils and vitamin A concentrates) a correction procedure based on the Morton–Stubbs principle[2] was considered sufficient. For oils in the second category (comprising whale-liver oils and other oils having a high proportion of irrelevantly light-absorbing materials) a chromatographic step should precede the determination of extinction and the application of correction. All measurements should be made on the unsaponifiable matter of the oils. It was suggested that this should be isolated by the method described in the United States Pharmacopeia.

The Commission organized three collaborative experiments, in which laboratories in Europe, Japan and the United States co-operated. Thirty-seven laboratories participated in the first experiment, thirty-four in the second and nine in the third.

The main purposes of the experiments were: (1) to ascertain the loss of vitamin A in isolating unsaponifiable matter of oils according to the method of the United States Pharmacopeia; (2) to investigate whether *iso*propanol and absolute ethanol could be used as alternative solvents in measuring extinction; (3) to determine the constants for a correction formula based on the Morton–Stubbs principle[2]; (4) to ascertain the loss of vitamin A in a chromatographic method suggested for samples in the second category; (5) to investigate the selectivity of this method; (6) to compare two techniques for following the movement of vitamin A through the chromatographic column; and (7) to estimate the experimental errors in the vitamin A potencies of oils in both categories as assayed by the procedure suggested.

A vitamin A reference standard containing all-*trans* vitamin A acetate in vegetable oil (nominal potency 100,000 I.U. per gm.) and samples of oils belonging in the second category were used as test materials.

In the chromatography, the unsaponifiable matter of the sample was passed through a column of weakened alumina and the vitamin was eluted with mixtures of light petroleum and ether. The movement of the vitamin was followed by testing aliquots of the eluate with antimony trichloride solution and, in the third experiment, alternatively by observing the column in weak ultra-violet light. Two different samples of alumina were used by most participants.

A statistical screening procedure, based on Chauvenet's criterion[3], was applied to the results.

The main outcome of the experiments can be summarized as follows. The average loss of vitamin A in isolating the unsaponifiable matter of the vitamin A reference standard was found to be 1·2 per cent in

College of S

the first experiment and 1·2–1·5 per cent in the second. *Iso*propanol and absolute ethanol could not be recommended as alternative solvents, because the respective E_{310}/E_{325} and E_{334}/E_{325} ratios differed significantly in the two solvents, which gave rise to systematic errors when correction was applied. The correction formula derived for *iso*propanol from the results of the first and second experiments was:

$$E_{325}\text{ corr.} = 6{\cdot}815\,E_{325} - 2{\cdot}555\,E_{310} - 4{\cdot}260\,E_{334}$$

The average loss of vitamin A in chromatographing the unsaponifiable matter of the vitamin A reference standard amounted to 2·4 per cent irrespective of the kind of alumina used. The average total loss of vitamin A, that is, the losses in isolating and chromatographing the unsaponifiable matter, was 3·5–4 per cent. After chromatography the samples of oils belonging in the second category readily met the specifications laid down for oils in the first category. The two procedures for following the movement of vitamin A through the column were equally efficient and could thus be recommended as alternative techniques. The inter-laboratory error (s) at $P = 0{\cdot}95$ for a duplicate assay of vitamin A potency was estimated at 6–8 per cent for an oil in the first category and at 10–14 per cent for an oil in the second category. The error of the mean of assays performed at n different laboratories—each of them making a duplicate assay—will accordingly be $s/\sqrt{n}$.

For vitamin A oils showing negligible amounts of irrelevant light absorption, the corrected E value should theoretically be identical with the uncorrected E value but, because of the experimental error due to the correction procedure, positive corrections must sometimes be encountered. About half the assays on the vitamin A reference standard in the first and second experiments showed positive corrections. In the first experiment 14 out of 15 positive corrections did not exceed 2·5 per cent and in the second 29 out of 30 positive corrections did not exceed 3·5 per cent.

The Commission now makes the following recommendations for the assay of vitamin A oils:

1. All oils shall be saponified, and the assay made on the unsaponifiable matter.

2. The unsaponifiable matter shall be isolated by the method of the United States Pharmacopeia XV [4].

3. All spectrophotometric measurements shall be made in *iso*propanol as solvent.

4. Oils shall be considered in two categories:

Category 1: those oils the unsaponifiable matter of which has an absorption maximum lying within the region 323–327 mμ and an extinction ratio E_{300}/E_{325} not exceeding 0·73.

Category 2: those oils the unsaponifiable matter of which has an absorption maximum lying outside the region 323–327 mμ or an extinction ratio E_{300}/E_{325} exceeding 0·73.

5. For oils in category 1, the E_{310}, E_{325} and E_{334} values of the unsaponifiable matter shall be measured and a correction applied according to the formula:

$$E_{325}\text{ corr.} = 6{\cdot}815\,E_{325} - 2{\cdot}555\,E_{310} - 4{\cdot}260\,E_{334}$$

6. For oils in category 2, the unsaponifiable matter shall be chromatographed according to a prescribed procedure. Provided the chromatographed unsaponifiable matter satisfies the criteria for category 1 oils, its E_{310}, E_{325} and E_{334} values shall be measured and a correction applied as directed under 5.

7. Corrected E_{325} value shall be used for calculating vitamin A potency, except in the cases mentioned under 8.

8. A corrected E_{325} value which lies within ± 3·0 per cent of the uncorrected value shall be regarded as equal to the uncorrected value for the purpose of evaluation, and the uncorrected value shall be used for calculating vitamin A potency. A corrected E_{325} value which is greater than 1·030 times the uncorrected value shall be re-determined and, if confirmed, treated as a special case between buyer and seller.

9. The E_{325} value is converted into $E^{1\%}_{1\text{cm.}}$ 325 mμ. The vitamin A potency of the sample, expressed in I.U. per gm., is obtained by multiplying the $E^{1\%}_{1\text{cm.}}$ 325 mμ value by 1830 [5], that is, the factor of the reference quoted, taken to three significant figures.

Detailed reports of the Commission's collaborative work and of the recommended procedure for assay will be published elsewhere.

CORRECTION FOR THE GAMMA-RAY SENSITIVITY OF THE BETA-COUNTER IN THE STANDARDIZATION OF COBALT-60 BY THE BETA–GAMMA COINCIDENCE METHOD

By B. OWEN and R. A. LLOYD

National Physical Laboratory, Teddington, Middlesex

THE standardization of radioactive isotopes by the beta–gamma coincidence method involves correcting the observations to obtain the true disintegration rate[1,2]. Some of these corrections, such as the natural backgrounds in the beta- and gamma-counters, can be determined without difficulty. The correction for the γ-ray sensitivity of the beta-counter, however, is usually made by screening the counter from the source by placing between them an absorber of such a thickness that it absorbs all the β-radiation. The objection to this method is that the absorber usually alters the γ-ray sensitivity of the beta-counter.

In an attempt to solve this problem for cobalt-60 we have incorporated a pulse-amplitude analyser following the β-ray detector of the beta–gamma coincidence-counting equipment. This equipment[3] consists essentially of two scintillation counters, one containing a thin anthracene crystal as the beta-counter and the other a thick crystal of activated sodium iodide as the gamma-counter.

Pulses lying within a voltage-range V to $(V + \Delta V)$ are passed by the analyser to the coincidence unit, and finally counted in the β-scalers. As V is varied, the β-counting rate will alter in a manner similar to the energy distribution of the original β-particles.

The beta-counter will also detect secondary electrons caused by the interaction of the cobalt-60 γ-rays with the crystal and surrounding material. It is the detection of these secondary electrons which gives rise to the 'γ-ray sensitivity of the beta-counter'. For cobalt-60 the energies of these electrons range from zero to 1·33 MeV., which is the energy of the higher of the two γ-rays. The β-particles range in energy from zero to 0·3 MeV. An absorber thick enough to absorb electrons up to 0·3 MeV. will cut off the β-radiation, but the residual counting rate with the absorber will not necessarily be the same as the γ-counting rate without the absorber.

We have measured the pulse-output distribution from the beta-counter, both with and without an absorbing screen in front of the anthracene crystal. Fig. 1 shows the result obtained. Without an absorber, a curve resembling the usual β-spectrum is obtained; with an absorber, the distribution appears flat. Measurements above the end-point energy of the β-spectrum shows that the γ-efficiency is increased by the interposition of an aluminium absorber 0·5 mm. thick between the source and the counter. This would also probably be the case when the analyser channel is set to record β-particles. That is, the standardization of cobalt-60 with this equipment, using a conventional absorber, will be erroneous because the γ-ray sensitivity of the counter is increased by the use of an absorber.

It is reasonable to assume that because the pulse distribution appears flat with an absorber, it will also be flat without an absorber (although not the same in magnitude). If this were so, then a variation of the analyser channel position would vary the β-efficiency of the beta-counter, but its γ-efficiency would remain constant (channel width ΔV and amplifier gain constant). This can be shown to be one of the conditions for the β-counting rate to be a linear function of the coincidence-counting rate.

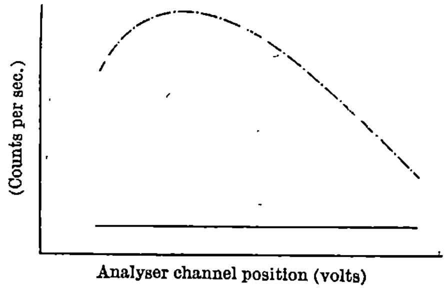

Fig. 1. Output of the anthracene β-detector with (full line) and without (pecked line) an absorbing screen

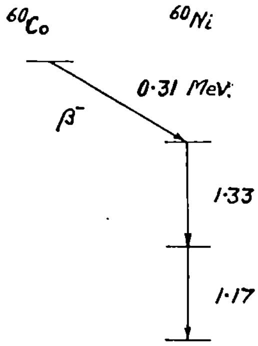

Fig. 2. Cobalt-60 decay scheme used for equation 5 (neglecting the weak β-branch)

For, considering the decay scheme shown in Fig. 2, if $(N_\beta + N_{\gamma\,\text{in}\,\beta})$ is the β-counting rate for any particular setting of the analyser channel, e_β the efficiency of the beta-counter for the β-rays, and $(e_1 + e_2)$ the efficiency of the beta-counter for the two γ-rays from cobalt-60, then

$$(N_\beta + N_{\gamma\,\text{in}\,\beta}) = N_0' e_\beta + N_0 (e_1 + e_2) \qquad (1)$$

where N_0 is the true disintegration rate.

Similarly,

$$N_\gamma = N_0 (E_1 + E_2) \qquad (2)$$

where N_γ is the counting rate from the gamma-counter, the efficiency of which is $(E_1 + E_2)$ for the two γ-rays from cobalt-60. In the experiment, $(E_1 + E_2)$ is kept as constant as possible, that is to say:

$$N_\gamma = N_0 (E_1 + E_2) = \text{const.} \qquad (3)$$

If $(N_{\beta\gamma} + N_{\gamma\gamma})$ is the counting rate from the coincidence circuit,

$$(N_{\beta\gamma} + N_{\gamma\gamma}) = N_0 e_\beta (E_1 + E_2) + N_0 (E_1 e_2 + E_2 e_1) \qquad (4)$$

A re-arrangement of equations (1), (2) and (3) gives

$$(N_{\beta\gamma} + N_{\gamma\gamma}) = (N_\beta + N_{\gamma\,\text{in}\,\beta})(E_1 + E_2) - N_0 (E_1 e_1 + E_2 e_2) \qquad (5)$$

Equation (5) expresses the relation between the β-counting rate $(N_\beta + N_{\gamma\,\text{in}\,\beta})$ and the coincidence counting rate $(N_{\beta\gamma} + N_{\gamma\gamma})$. It is assumed that the usual corrections for backgrounds, accidental coincidences and dead-time losses have already been made to the observations.

Equation (5), expressed in the form $y = mx + C$, will be linear when the terms corresponding to m and C are constant. It is arranged experimentally that $m = (E_1 + E_2)$ is constant; but in the case of $C = N_0 (E_1 e_1 + E_2 e_2)$, N_0 is a constant, allowing for radioactive decay during the measurement, therefore the required condition is that $(E_1 e_1 + E_2 e_2)$ must be constant. If $(E_1 e_1 + E_2 e_2) = \text{const.}$, all terms are finite and E_1 and E_2 are constant, then either $\Delta e_1 / \Delta e_2 = - E_2 / E_1$ or $(e_1 + e_2) = \text{const.}$ If, therefore, the γ-spectrum of the beta-counter is indeed flat, then one of the conditions for $(N_\beta + N_{\gamma\,\text{in}\,\beta})$ to be a linear function of $(N_{\beta\gamma} + N_{\gamma\gamma})$ is realized. Furthermore, the slope $(E_1 + E_2)$, in conjunction with the γ-counting rate, will give N_0 without any necessity for using an absorbing screen. Fig. 3 shows a hypothetical plot of this linear function. The straight-line plot extends from $e_\beta = 0$ to an upper limit determined by the apparatus.

Measurements on cobalt-60 so far have shown that this line has a slight curvature, the slope varying by about 3 per cent over the range of measurement. A

Fig. 3. Illustrating equation 5 when $(N_{\beta\gamma} + N_{\gamma\gamma})$ is a linear function of $(N_\beta + N_{\gamma\,\text{in}\,\beta})$

least-squares analysis of the points on the line gives a standard deviation of ± 0·5 per cent for the slope, but in view of the curvature, the disintegration rate cannot as yet be determined to better than ± 1·5 per cent. The curvature appears to be influenced by several experimental variables which are at present being investigated.

Equation (5) can be investigated by other methods for varying e_β. For example, it is possible to vary e_β by placing absorbers of various thicknesses in front of the beta-counter, and it can now be seen that a measurement with an absorber which cuts off all the β-radiation represents only one point on this line; a measurement without an absorber constitutes another point, and the usual method of evaluating N_0 from these two measurements is really a determination of the slope of this line. The apparent disintegration rate is less or greater than the true one according to whether the absorber increases or decreases the γ-efficiency of the beta-counter. This can be shown in a similar way to the argument involving equations (1) to (5), except that now the γ-efficiency of the beta-counter $(e_1 + e_2)$ is changed by the absorber to $(e_1' + e_2')$.

Another way of varying e_β is to alter the distance between the source and the beta-counter, when e_β will vary approximately as the solid angle between the source and the counter. But a plot of $(N_{\beta\gamma} + N_{\gamma\gamma})$ against $(N_\beta + N_{\gamma\,\text{in}\,\beta})$ will not then give a straight line, because the γ-efficiency of the beta-counter will also vary with the solid angle. This may account for the variation in disintegration rate which has been observed in this laboratory using the conventional absorber method with varying geometrical arrangements. Lastly, it may be noted that measurements on sources of different strengths should not affect the slope of the line, provided that the γ-efficiency of the gamma-counter remains constant.

It is hoped to pursue this work on the standardization of cobalt-60, to investigate the method more fully, and to apply the method to other suitable isotopes.

This work has been carried out as part of the research programme of the National Physical Laboratory, and is published by permission of the Director of the Laboratory.

EVIDENCE FOR A PROTEIN COMPONENT IN THE MIDDLE LAMELLA OF PLANT TISSUE: A POSSIBLE SITE FOR INDOLYLACETIC ACID ACTION

By B. Z. GINZBURG
Botany Department, The Hebrew University, Jerusalem

WHILE looking for a method for separating root tips into single cells, I attempted to use calcium-binders, following Northcraft[1]. Similar methods have been used for separating animal tissue[2-4]. Northcraft used ammonium oxalate. The actions of ammonium oxalate, citrate and ethylene diaminetetraacetic acid were compared on the assumption that calcium stabilizes the intercellular cement, as cited by Bonner[5]; calcium pectate is found in the middle lamella. The stabilizing action of calcium might also be due to its decreasing the zeta-potential of the colloidal pectins. Zwilling[4] obtained separation in animal tissue within 20–30 min., using ethylene diaminetetraacetic acid. Chelating compounds having high affinity for calcium should, therefore, readily and quickly also separate plant tissue.

The following method was used. The 1-mm. root tips of Alaska pea seedlings grown for 45–50 hr. were used. The root tips were immersed in 1 ml. of the test solution in small vials, and at the appropriate times they were put on slides in a drop of distilled water. By tapping gently on the cover glass separation of root tips occurs. Under the microscope the percentage of separation may be estimated.

Some typical results of the first sets of experiments are shown in Figs. 1, 2 and 3. The following emerges:

(1) The degree of separation is dependent upon concentration up to 0·1 *M* ethylene diaminetetraacetic acid. At 0·01 *M* no separation was obtained, even at high temperatures. Above 0·1 *M* the extent of separation again decreases. This decrease is being

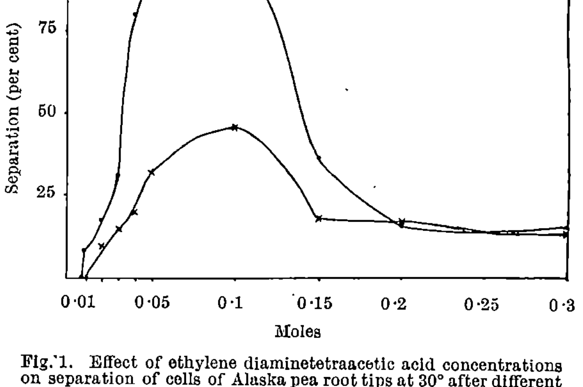

Fig. 1. Effect of ethylene diaminetetraacetic acid concentrations on separation of cells of Alaska pea root tips at 30° after different times. Solution *p*H 8·0. ×, 9-hr. treatment; ●, 16-hr. treatment

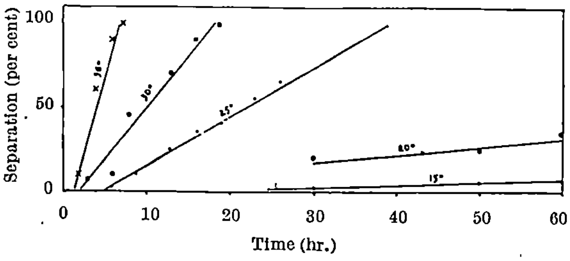

Fig. 2. Effect of temperature and time on the separation of cells of Alaska pea root tips. Ethylene diaminetetraacetic acid concentration 0·1 *M*. *p*H 8·0

investigated further. The active concentrations are very high as compared with those normally used in biological experiments and also as compared with those used for estimating calcium. (2) The rate of reaction is rather slow, compared with other known chelating reactions *in vitro* and *in vivo*. (3) The Q_{10} of the separation is very high, indicating a high 'energy of activation' which was calculated to be of the order of 35–40,000 cal. (4) Dependence on *p*H up to 11·0 is similar to, but not identical with, the calcium-chelating power of ethylene diaminetetraacetic acid as a function[6] of *p*H. This seems to indicate that an additional factor, apart from calcium chelating, is involved in the reaction.

These results cannot be interpreted as the mere removal of exchangeable calcium from the intercellular cement.

A working hypothesis was assumed as follows. The calcium ion is hidden by some structure and is therefore not accessible to ethylene diaminetetraacetic acid chelating action. This stabilized structure is part of the intercellular cement. Now, it seemed reasonable to assume that such a structure is part of a macromolecule existing in the middle lamella. It might be a pectic substance or other macromolecule that has not yet been identified in the middle lamella of plants, such as a protein or protein-containing complex. If such a macromolecule is involved, the use of the known agents breaking intramolecular links should modify the effect of ethylene diaminetetraacetic acid. Three substances were therefore selected. Urea, for breaking hydrogen bonds; thioglycolate, for breaking S—S bonds; and butanol, for breaking the hydrophobic linkages (Tables 1, 2 and 3).

Ethylene diaminetetraacetic acid 0·1 *M*	Ethylene diaminetetraacetic acid 0·1 *M* + 5 per cent butanol	Butanol 5 per cent
40	100	0

The results of these experiments are in accord with the view that there is a protein component in the intercellular cement, as all the denaturing agents favoured the destruction of the intercellular cement. Particularly the action of thioglycolic acid supports this, if its action is indeed only on S—S bonds, which are known to occur in proteins.

Further evidence for this view was obtained from the action of proteolytic enzymes. Pepsin gave good separation of the cells, cathepsin *C* gave slight separation. Other enzymes, such as papain, trypsin and chymotrypsin, digest the whole tissue; no separation could be determined.

If the action of ethylene diaminetetraacetic acid is a chelating one, then other chelating compounds should also be effective in the presence of modifying agents such as thioglycolic acid (Table 4).

It will be seen that different compounds having different structures and having only chelating action in common work on the system in much the same way.

From the work of Heath and Clark[7,8], Weinstein *et al.*[9] and Bennet-Clark[10], it has been suggested that ethylene diaminetetraacetic acid and other chelating compounds have a growth-stimulating activity, and that the action of indolylacetic acid itself could be similarly interpreted as being due to chelating action. Indolylacetic acid, therefore, should also effect the separation of cells in the presence of a suitable protein-denaturing agent (Table 5).

If, to accept the old idea of Heyn, which has recently been recalled by Bennet-Clark[10] and by Bonner *et al.*[11], the effect of indolylacetic acid is to plasticize the cell wall or, in other words, to decrease the wall pressure of the cell, the following might be suggested. The 'wall pressure' can be seen as having two components—the pressure of the rest of the tissue and the tensile properties of the cell wall, that is, the wall pressure proper. Now the indolylacetic acid might act on the intercellular cement, and by partially loosening it, decrease the effect resulting from the pressure of the neighbouring cells. Alternatively, we may look upon the cement as part of the wall and the change of structure caused by chelating of the metal, thus affecting the tensile strength of the wall.

It may therefore be concluded that a metal ion is in some way bound in the middle lamella, possibly by a protein or protein complex. This might explain the function of the proteins which occur in the middle lamella. In addition, under the extreme conditions used, indolylacetic acid could be shown to have a clear chelating action in the presence of suitable modifiers. These two facts together suggest that indolylacetic acid may indeed act as a chelating agent. These facts would also be in agreement with the views of Burström[12], that ethylene diaminetetraacetic acid may act by competitive chelating action.

This paper is part of a Ph.D. thesis to be submitted to the Hebrew University, Jerusalem. I am indebted to Prof. M. Evenari, Dr. A. M. Mayer and Dr. A. Poljakoff-Mayber for their guidance, interest and encouragement during the time that this research was carried out.

RESPONSES OF A FERN APEX TO GIBBERELLIC ACID, KINETIN AND α-NAPHTHALENEACETIC ACID

By PROF. C. W. WARDLAW and G. C. MITRA

Department of Cryptogamic Botany, University of Manchester

THE reactivity of the shoot apex of *Dryopteris austriaca* (*D. aristata*) to the direct external applications of physiologically active substances[1,2] has been further investigated during treatments with gibberellic acid, kinetin and α-naphthaleneacetic acid. These substances have recently been shown to produce remarkable physiological and morphological changes when applied externally to leaves, etc., and in tissue culture[3-14].

Large, bare apices of *Dryopteris austriaca* were treated, as already described[1,2], for periods of about three weeks with aqueous solutions of gibberellic acid (100 mgm./l., 10 mgm./l.), kinetin (100 mgm./l., 10 mgm./l., 1 mgm./l., 0·1 mgm./l.), and α-naphthaleneacetic acid (1,000 mgm./l., 100 mgm./l., 10 mgm./l., 1 mgm./l.) and closely examined at frequent intervals. Control apices were similarly treated but with water throughout. The experiments with gibberellic acid and kinetin were undertaken in May and July, and those with α-naphthaleneacetic acid in January, February, May and July. (During the winter months the apical meristem of *Dryopteris* is inactive; in May it is becoming active, and in July it is more or less at the height of its activity.)

Gibberellic acid. In May, 10 mgm./l. gibberellic acid stimulated the growth and morphogenetic activity of the apex, an average of eight primordia being formed as compared with three in the control during the same period; but with 100 mgm./l. only three new primordia were formed. In July, 10 mgm./l. applications had a smaller stimulatory effect (an average of six primordia as compared with four in the control), whereas an average of eight primordia was obtained with 100 mgm./l. The number of primordia formed both during and after the gibberellic acid treatment was always greater than that in the controls. The older primordia in treated apices showed an increase in size but no marked elongation of the rhizomatous stem was observed. The normal course of tissue differentiation was not modified.

Kinetin. At 100 mgm./l. kinetin completely inhibited the growth of apices and eventually killed them. With 10 mgm./l. and 1 mgm./l. of kinetin, no new primordia were formed during a period of four

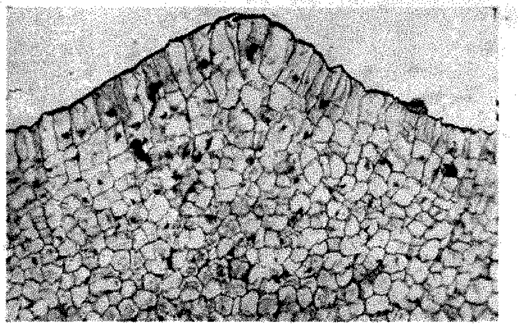

Fig. 1

weeks after the cessation of the treatment in either the May or July collections of apices. The apices underwent a considerable general increase in size, with formation of new scales around the base of the meristem and a conspicuous growth of the bases of the older scales which had been removed. At both concentrations, primordia 1 and 2 disappeared during the period of treatment and no organ re-formed in these sites when the treatment was discontinued. Later in the experiment, when the treatment had been discontinued, the growth of primordia 3 and 4 did not continue, and they were gradually transformed into flattish mounds. Primordia 5, 6, 7 and 8 likewise did not increase in size and were overtaken by the rapid growth of the surrounding tissues and old scale bases. Treatment with 0·1 mgm./l. kinetin slightly stimulated the formation of leaves, an average of six primordia being obtained as compared with four in the control. In microtome sections of treated apices it was seen that the normal histological organization had been profoundly affected and that tissue differentiation, for example, of the prevascular tissue had not occurred (Fig. 1). The general effect could be described as one in which cell division had been followed by a more or less uniform formation of parenchyma throughout the apical cone.

α-Naphthaleneacetic acid. Applications of 1,000 mgm./l. killed both winter and summer apices. In the winter experiments, treatments with 100 mgm./l. and 10 mgm./l. induced a very marked enlargement and saucer-shaped upgrowth of the subapical region (Fig. 2), indicating that in the so-called 'dormant' winter apex some growth potential still persists in this region. When treatment was discontinued, this subapical growth gradually became obscured by growth at the base of the apical cone. The latter, which includes the apical meristem, did not increase in size, but gradually became scaly right to the summit in some cases. In a February experiment, with controlled temperature (22–24° C.) and lighting (150-ft.-candles for 16 hr. per day), one or two new primordia were formed in some of the apices after the cessation of the treatments. A similar formation of primordia was observed in the controls.

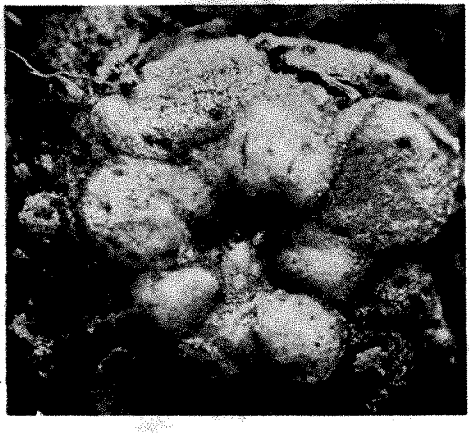

Fig. 2

In the summer experiments with 100 mgm./l., no new primordia were formed during the period of treatment, and the subapical region did not form the characteristic upgrowth already described. The apical meristem appears to have retained its characteristic property of self-maintenance in the embryonic state and, when the treatment was discontinued, formed an average of three new primordia in three weeks. 10 mgm./l. did not seem to affect the growth of the meristem either during or after the treatment. Applications of 500 mgm./l. inhibited the growth of the meristem in some specimens while in others it stimulated growth in the subapical region, but did not induce the saucer-shaped upgrowth. Treatment with 1 mgm./l. was slightly stimulatory to the formation of leaves by the apex.

The results obtained with gibberellic acid are in general accord with previous findings with other plants, except that there was no notable elongation either of young primordia or of the stem. Apices collected in May and July responded differently to the two concentrations; such seasonal differences in apical reactivity have frequently been noted in this laboratory. In the experiments under consideration they are especially interesting in respect of the responses of winter and summer apices to different concentrations of α-naphthaleneacetic acid. The reactivity of different regions of the apex to α-naphthaleneacetic acid was also a notable feature and one which needs fuller investigation.

Kinetin is known to have both inhibitory effects[9,15] and stimulatory effects on cell division[5,6] and enlargement[7]. In *Dryopteris*, kinetin stimulates cell division and parenchymatous enlargement throughout the whole apical region. As a result, the apical organization is so modified that it no longer gives rise to the characteristic pattern of tissue differentiation that normally attends the inception and formation of organs.

These observations will be considered in greater detail elsewhere.

We are indebted to Mr. E. Ashby and Mr. G. Barker for the photographs.

Irreversible Processes in Physical Theory

PROF. K. R. POPPER[1], in several communications on the nature of irreversible processes, has formulated the idea that the irreversibility of a simple physical process arises from the causal impossibility of arranging for coherence between the independent oscillators required for the operation which is the inverse of that process.

Prof. E. L. Hill and A. Grünbaum[2] believe that the point raised is sufficiently important to deserve formulation as a general principle in physics. They suggest that the distinction between physically reversible and irreversible processes is parallel to that between closed and open systems. A closed system is quasi-periodic and causally reversible. An open system is aperiodic and irreversible. In particular this distinction requires that the process of radiant heat transfer in an infinite universe be just as irreversible on the quantum theory as on classical mechanics. The difficulty of this point has already been stressed by Einstein.

Popper casts doubt on the generality of the principle of Hill and Grünbaum. He claims, for example, that the system of the Sun and a comet moving on a hyperbolic orbit, while undoubtedly an open system, is definitely one we should like to regard as reversible. He then cites two further examples to elaborate his point with regard to the relation between reversibility and coherence. A spheroidal reflector with an oscillator at each conjugate focus constitutes a reversible system. A similar system but with a scattering instead of a reflecting surface, even if perfectly externally insulated, does not. This, says Popper, arises from the impossibility of arranging for coherence between the oscillators on the scattering surface by means of any centrally directed mechanism, thereby claiming that his principle of coherence is of more general validity than that of Hill and Grünbaum.

There is, however, an alternative way of describing the distinction between causally reversible and causally irreversible processes and one which I claim is of higher generality than that advanced by Popper.

In the description of a mechanical system by classical mechanics the parameters used, namely, the co-ordinates and momentum, give a complete description of the path of every particle of the system, and the reversibility of these paths is ensured by the ordinary laws of motion which are invariant with respect to change from $+t$ to $-t$. When, however, we come to describe a system by means of parameters which have only a statistical significance, a complete description of the path of every particle concerned is no longer obtained. The inverse process is then not necessarily a microscopic copy on a reversed time-scale of the direct process. The inverse process no longer completely undoes the action of the direct and the change is essentially irreversible. Thus, as I have pointed out elsewhere[3], a pure radiative process, with the optical paths of all rays concerned completely determined, is reversible. A conductive process is described by such statistical terms as mean free paths or mean collision frequencies and is accordingly irreversible.

The distinction between statistical and precise descriptions of the process gives a natural interpretation of the examples raised by the other authors. Thus, Popper's second example is irreversible because the properties of the oscillators on the absorbing screen can only be described by statistical qualities. His first example is reversible because it is possible to define the precise path of every quantum from one oscillator to the other. The addition of any scattering material, for example, smoke, within the reflecting body would diffuse the optical paths which would then only have statistical significance and the whole process of energy exchange would become irreversible. Again, the distinction between the description of divergent radiation on the wave and quantum theories disappears in this new view. Both processes are thermodynamically equivalent; one because the intensity of the radiation is progressively decreased and the other because the probability of finding a quantum in unit volume of space decreases at the same rate.

[1] Popper, K. R., *Nature*, **177**, 538; **178**, 382 (1956); **179**, 1297 (1957).

[2] Hill, E. L., and Grünbaum, A., *Nature*, **179**, 1296 (1957).

[3] Bosworth, R. C. L., "Transport Processes in Applied Chemistry", 158 (Pitman, 1956).

PROF. R. C. L. BOSWORTH's view, if I understand him properly, is that held by most physicists since the time of Boltzmann. It has become famous through Eddington's metaphor of the arrow of time. It consists of the following two theses: (1) Every non-statistical or 'classical' mechanical process is reversible; this, to quote Prof. Bosworth, "is ensured by the ordinary laws of motion which are invariant with respect to change from $+t$ to $-t$"; (2) irreversibility enters into physics "by means of parameters which have only a statistical significance"; or in Eddington's way of putting it, the increase of entropy (or of statistical disorder) determines the "arrow of time".

It was precisely this position, so ably restated in Prof. Bosworth's communication, which I briefly sketched at the beginning of my communication "The Arrow of Time"[1], which started this correspondence, and which I tried to criticize in that letter by giving a counter example to thesis (1). I did not discuss my reasons for disbelieving thesis (2).

Prof. Bosworth questions my counter example in its optical form in which it appears in my reply to the communication by Profs. Hill and Grünbaum[2], by asserting that "the properties of the oscillators on the absorbing screen can only be described by statistical qualities". But there is surely some confusion here. We may assume—and this becomes clear if we revert to my original example of a water wave—that all the elementary processes are purely mechanical and *prima facie* deterministic (admittedly an over-simplification): only then does it become quite clear that the process in which we are interested is theoretically fully reversible, since we may in fact construct a large number of oscillators, operating coherently, which actually reverse it. But if we look more closely at the way in which these oscillators are controlled so as to make them cohere, we find that they must, essentially, be controlled from one centre from which some signal—for example, a light signal—must run to the places where the oscillators are situated.

Thus although the elementary classical physical processes involved in an expanding wave are reversible, we find that in order to obtain the reversion, that is, the contracting wave, we always need a wave that spreads from a centre, or something equivalent to it. If not steered by an expanding wave, the contracting wave, though not in itself physically impossible, would nevertheless have the character of a physical miracle: it would be like a conspiracy, undertaken by many people, each carefully acting so as to support all the others, but without any previous arrangement, or anything like a prepared plan.

This explains why, although theoretically possible, spontaneous contracting waves do not in fact occur: they are theoretically possible, but causally, and therefore physically, impossible.

Prof. Bosworth's analyses of my examples are inadequate: in the reversible case of the ellipsoid mirror (called by Prof. Bosworth my first example) contracting waves never occur unless they are excited by an expanding wave; and the example was designed to show, among other things, that even perfect reversibility is not yet causal reversibility.

Of course all these experiments are idealizations, and, in reality, there would be in all these cases an increase of entropy. So much is common ground. Also, in explaining any concrete mass phenomena, we have of course to use statistical methods.

Although my whole analysis was only intended to throw light on (1) by showing that even elementary classical processes may be in an important sense physically irreversible, I may perhaps say, very briefly, why I distrust (2). The suggestion has been made (first by Boltzmann himself) that the arrow of time is, either by its very nature, or by definition, connected with the increase in entropy; so that entropy cannot decrease in time because a decrease would mean a reversal of its arrow, and therefore an increase relative to the reversed arrow. Much as I admire the boldness of this idea, I think that it is absurd, especially in view of the undeniable fact that thermodynamic fluctuations do exist. One would have to assert that, within the spatial region of the fluctuation, all clocks run backwards if seen from outside that region. But this assertion would destroy that very system of dynamics on which the statistical theory is founded. (Moreover, most clocks are non-entropic systems, in the sense that their heat production, far from being essential to their function, is inimical to it.)

I do not believe that Boltzmann would have made his suggestion after 1905, when fluctuations, previously considered no more than mathematically calculable near-impossibilities, suddenly became the strongest evidence in favour of the physical reality of molecules[3]. (I am alluding to Einstein's theory of Brownian motion[4].) As it is, a statistical theory of the arrow of time seems to me unacceptable. The purpose of my first communication was to propose an example of a non-statistical process such that no physicist who finds a film strip of this particular process would need to doubt where the film begins and where it ends: he could determine its arrow of time.

Life-time of an Artificial Earth Satellite

Fejer[1] and Scott[2] have given simple methods for estimating the remaining life-time of an artificial Earth satellite. Their methods do not apply when the eccentricity is small, and it is not immediately clear why the estimates are so good (cf. particularly Scott's data for the descent of the rocket of 1957 Alpha Satellite). Nevertheless, it has been found possible to show that their formulæ are accurate so long as the eccentricity is not too large.

A strict application of first-order perturbation theory to the motion of a satellite subjected to a purely axial force with constant drag coefficient shows that the rate of descent of apogee per revolution is given by

$$\frac{\mathrm{d}H_a}{\mathrm{d}n} = - \delta . H^{a2} \int_{-\pi}^{\pi} (1 + \cos\theta) \frac{\sqrt{1 + 2e\cos\theta + e^2}}{(1 + e\cos\theta)^2} \rho(\theta)\, \mathrm{d}\theta \quad (1)$$

where H_a is the height of apogee above the centre of the Earth, $\delta = SC_D/m$ in the usual notation, θ is the anomaly, e the eccentricity, n the number of revolutions, and ρ the density. The rate of descent of perigee $\mathrm{d}H_p/\mathrm{d}n$ is given by a very similar formula. If e is small enough and if a simple exponential atmosphere is an adequate model, the integral (1) may be evaluated exactly (as was noted by Scott) to give

$$\frac{\mathrm{d}H_a}{\mathrm{d}n} = - 2\pi\delta H_a{}^2\rho_o \exp\{\beta(H_o - H) - \beta h_o\} [I_0(\beta h) + I_1(\beta h)] \quad (2)$$

where $H = \frac{1}{2}(H_a + H_p)$, $h = \frac{1}{2}(H_a - H_p)$, ρ_o is the density at height H_{po}, β the lapse-rate of the atmosphere, and a suffix o denotes an initial value. I_0 and I_1 are Bessel functions of the first kind and imaginary argument. The formulæ given by Fejer and Scott are the asymptotic forms of this equation for large βh. Thus the Scott–Fejer analysis seems to require that e should be both large and small.

Equation 2 and the very similar formula for $\mathrm{d}H_p/\mathrm{d}n$ may be regarded as equations of motion for H_a and H_p (or H and h) as functions of n. Since βH_{po} is large, they may be integrated when e is small, to give

$$\exp\{\beta(H_o - H)\} = \frac{h_o I_1(\beta h_o)}{h I_1(\beta h)} \quad (3)$$

and

$$h_o{}^2 - h^2 = 4\pi\delta H_o{}^2\rho_o \,.\, h_o \exp(-\beta h_o) \,.\, I_1(\beta h_o) \,.\, n \quad (4)$$

From equation 4 it follows that:

$$e_o{}^2 - e^2 = 4\pi\delta\rho_o \,.\, h_o \exp(-\beta h_o) \,.\, I_1(\beta h_o) \,.\, n \quad (5)$$

The linear variation of e^2 with n also follows from the analysis of Fejer and Scott. The fundamental reason for the success of their work is that the relation is in fact valid down to $e = 0$. From it, we may deduce that the remaining life-time of the satellite is

$$t_o = \tfrac{3}{4} e_o \frac{T_o}{(-\mathrm{d}T/\mathrm{d}t)_o} \quad (6)$$

T_o being the initial period, and $(-\mathrm{d}T/\mathrm{d}t)_o$ the initial rate of decrease of the period; if this decrease is measured in seconds per day, t_0 is immediately expressed in days, which is convenient. Scott's equation 1 agrees with my equation 6 to order e_0, while Fejer's equation 7 is a direct consequence of my equation 4.

The relative error in equation 6 is believed to be of order e_0. A correction of this form would be of some significance for Satellite 1957 Beta, with its long life and high initial eccentricity, and an attempt is therefore being made to evaluate it.

Remanent Magnetization of Ancient Bricks

It has recently been suggested that, in the values of remanent magnetization of clay bricks fired in ancient times, there exists evidence of a secular decrease in the strength of the Earth's magnetic field[1,2]. It has been further suggested that the effect of such a change in magnetic field on the intensity of cosmic radiation incident upon the Earth would tend to falsify radiocarbon dating procedures based on an assumed constant intensity of cosmic radiation[3].

The conclusions based on the magnetization of ancient bricks have presupposed that this magnetization is proportional to the intensity of the Earth's magnetic field at the time the bricks received their original firing, provided that no high-temperature firings have intervened. In the procedure of E. Thellier[1,2,4], the magnetization, M, of the brick, as found, is measured at a standard temperature (60° C.). The brick is then fired at successively higher temperatures to 670° C., apparently in an inert atmosphere[2], and then allowed to cool from 670° to 60° in the present Earth's field, H'. The resulting magnetization of the brick, M', is then measured. The value of the Earth's field, H, at the time of the original firing, is assumed to be related to the above values by the equation:

$$H = H' M/M'$$

However, it has been shown in an earlier paper of E. Thellier[5] that the specific magnetization, σ, acquired by a given baked clay, when fired at 670° in a constant magnetic field of 13 gauss, can increase by a factor of 200 when the firing atmosphere is changed from nitrogen to illuminating gas. (Cf. Table 1, taken from ref. 5. T is the maximum firing temperature.)

It is proposed, therefore, that the apparently high value of remanent magnetization of ancient bricks can have been the result of the use of fuel-heated kilns during their original firing. The presence of incompletely burned products of combustion in such kilns could provide a reducing atmosphere comparable in effect to illuminating gas. This would tend to cause a higher value of magnetization to exist in the brick after cooling than would result from firing in an inert atmosphere.

Table 1. Specific Magnetization of Fired Clay ($\sigma \times 10^4$)

Temperature (° C.)	400°	580°	670°	870°
Oxygen	2·0	3·6	4·8	6·5
Nitrogen	2·6	4·5	10·0	570·0
Illuminating gas	520·0	4,750·0	2,000·0	36·0

If the possibility of the occurrence of such an effect has not been taken into account in the measurements of 'fossil' magnetization of ancient clays, the results may well lead to the deduction of an excessively high value of the magnetic field of the Earth at the time of the original firing.

We are indebted to Dr. L. S. Cressman and Mr. Thomas Newman of the University of Oregon for directing our attention to the measurements for dating by clay brick magnetization.

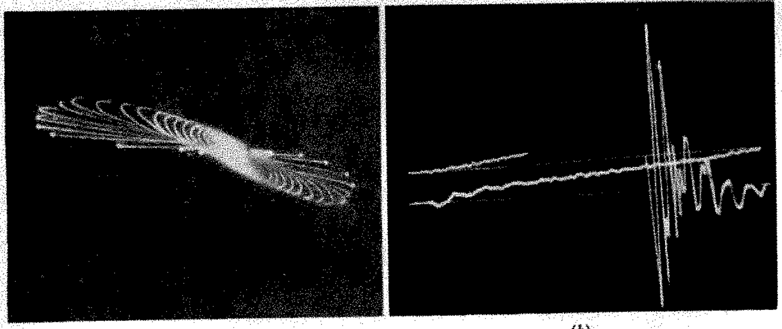
Abnormal Polarization of the Atmospheric Pulses reflected successively from the Ionosphere

While engaged in the determination of the direction of arrival of atmospherics by the conventional cathode-ray tube direction-finder, it was observed that, on occasions, for atmospherics of comparatively distant origin, there were elliptic patterns of gradually decreasing eccentricity and tilt-angle along with one or more linear responses, although when tested with the audio-frequency oscillations from a signal generator fed into the aerial system of the cathode-ray tube direction-finder, the fluorescent screen exhibited only the usual linear responses. It appears certain that these elliptic patterns are evidences of abnormal polarization of the atmospheric pulses reflected successively from the ionosphere, the linear responses being due to the direct (or ground-wave) atmospheric pulses. More than forty oscillograms showing the elliptic patterns and lines were recorded during the monsoon months of 1955. Usually the tilt-angle of the ellipses was found to decrease with the increasing order of ionospheric reflexion. A reversal in the direction of precession was noticed in few cases.

A typical record of the precessing ellipses with five or six straight lines bunched within a small angle along with the record of the wave-form of the atmospheric pulses simultaneously taken with the automatic atmospheric recorder[1] is shown in Fig. 1. The wave-form record reveals quasi-periodic pulses followed by a series of successive ionospheric reflexions. The distance of the lightning discharge yielding these records, as calculated from the observed time-interval between the successive reflexions, is about 500 km. The tilt-angle of the elliptic patterns was found to decrease from about 176° to about 167° and the phase-difference between the normal and abnormal components, as calculated from the observed ellipses, was found to increase steadily from about 40° to about 67° after six successive reflexions from the ionosphere.

It is suggested that the several straight lines, bunched within a small angle, were due to the



(*a*) (*b*)

Fig. 1. Oscillograms of (*a*) the elliptical patterns with gradually varying eccentricity and tilt-angle and (*b*) the corresponding wave-form recorded simultaneously with the automatic atmospherics recorder. Date, October 10, 1955. Time, evening

radiation which originated at the branching points of a long horizontal or slightly inclined lightning discharge from one cloud to another and reached the direction-finder directly. The quasi-periodic pulses observed in the wave-form pattern were due to the current variations at the branching points, and they were followed by the different orders of ionospheric reflexion. The horizontal length of the lightning channel responsible for the oscillograms, shown in Fig. 1, has been calculated and found to be about 7 km. This seems to be consistent with the observations of Shipley[2], who reported long horizontal channels along the lower edge of the cloud.

The possibility that abnormal polarization might be shown by the atmospheric pulses due to the zig-zag path of the lightning discharge was first pointed out by Adcock and Clarke[3]. The observed regular pattern of the precessing ellipses with continuously changing eccentricity and tilt-angle, however, strongly suggests that the effect of the random zig-zag path of the lightning discharge cannot be appreciable.

The experimental work was carried by Dr. B. A. P. Tantry and Mr. R. S. Srivastava under my guidance, as a part of the programme of a research project sponsored by the Council of Scientific and Industrial Research, New Delhi, to whom our thanks are due. A detailed paper will be published elsewhere.

Temperature Coefficient of Ultrasonic Absorption in Organic Liquids

FROM the data heretofore available in regard to the observed ultrasonic absorption and its ratio to the coefficient calculated on the basis of Stokes's and Kirchhoff's theories, the various organic liquids have been broadly classified[1,2] into four groups. Confining our attention to temperature variation alone, we find that, according to this classification, members of group *A*, consisting of non-associated polyatomic liquids, are expected to show a positive temperature coefficient of absorption, whereas the liquids in the other groups are expected to show a negative temperature coefficient. It may be remarked, however, that the grouping and also the temperature coefficient assigned to each group are on an empirical basis.

In the course of an exhaustive investigation carried out in this laboratory on the temperature variation of absorption coefficient in a large number of liquids, including several homologous series, it has been noticed that some liquids which fall in group *A* show a negative temperature coefficient of absorption instead of positive as expected. Aniline, hexadecane, 1-dodecene and amyl acetate are some of the liquids showing this behaviour. Further, in some of the homologous series such as the saturated hydrocarbons and 1-olefines it is seen that the temperature coefficient is positive for the lower members but becomes negative for the higher members, passing through a stage where the absorption coefficient is practically independent of temperature over the range of observation (15–60° C.), as, for example, for *n*-decane in the case of the saturated hydrocarbons and for 1-nonene in the case of 1-olefines. Some of the measurements are given in Table 1.

Liquid / Temp. (° C.)	$\alpha/\nu^2 \times 10^{17}$ (at 21 Mc./s.)					
	20°	25°	30°	35°	40°	45°
Aniline	66·7	60·0	54·5	51·5	49·0	48·2
Amyl acetate	86·0	84·3	82·9	81·5	79·8	79·2
n-Hexane	56·9	60·6	63·6	66·3	68·9	71·4
n-Decane	56·7	56·7	56·7	56·7	56·7	56·7
n-Hexadecane	97·8	95·4	91·9	88·9	86·2	83·8
1-Octene	57·6	57·4	57·4	57·5	57·9	58·6
1-Decene	51·4	49·5	47·8	46·3	44·5	44·2
1-Dodecene	72·6	68·0	65·5	62·3	59·5	57·1

The object of this communication is to report on the anomalies between our observations and the classification and to direct attention to the inadequacy of the present theories to explain them. The observation regarding negative temperature coefficient of absorption in some of the above-mentioned liquids, and also the reversal of temperature coefficient from the lower to the higher members of the homologous series, is not consistent with the present classification of liquids according to their sound absorption, nor is it accounted for by the Stokes's and Kirchhoff's theory of classical absorption.

By comparing the above observed values of sound absorption with those calculated according to the classical theory it is seen that in every case the measured value is larger. As is well known no theory is able uniquely to explain the excess absorption in all the liquids. The various theories[3,4] advanced so far are based on thermal relaxation, structural relaxation and bulk viscosity. A formula[5] lately given correlates the observed absorption to the classical absorption in terms of a function of γ, the ratio of specific heats, as

$$\frac{\alpha_{\text{obs.}}}{\nu^2} = \left(\frac{2/3}{5/3 - \gamma}\right)^4 \left\{ \frac{8\pi^2}{3v^3\rho} \left(\eta + \frac{3}{4} \frac{\gamma - 1}{c_p} K \right) \right\}$$

It may be remarked here that the existing classification of liquids into various groups is of an *ad hoc* nature and has to be examined closely.

The observation that some of the measured liquids do not fit into the present classification and that in a homologous series the temperature coefficient of absorption which is positive for the lower members changes to negative for higher members is being examined in terms of the available theories.

Detailed discussion of the topic will be published elsewhere.

Influence of Moisture upon the Dielectric Properties of Solid Powders dispersed in Liquid Paraffin

IT is known that various colloidally or coarsely dispersed systems show anomalous dielectric behaviour. Fricke[1] reported that an aqueous dispersion of solid particles or macromolecules showed a striking dielectric dispersion in the audio- and radio-frequency ranges, and he ascribed these effects to the polarization of oriented water molecules bound loosely at or near the surface of the dispersed phase. But the exact nature of the effect has not been established.

We have measured the dielectric constant and loss, ε' and ε'', of various suspensions or pastes consisting of inorganic or organic powders dispersed in liquid paraffin, over a frequency-range of 0·5–3,000 kc./s. by means of a conductance-capacitance bridge. As is shown in Fig. 1, pronounced dispersion was found with suspensions of titanium oxide in both its crystalline forms, anatase and rutile. The titanium oxide powders had been air-dried and contained about 0·7 per cent moisture by weight; the content of the powder was about 13 per cent by volume, and the dispersed systems remained sufficiently stable during measurements.

The effect was more pronounced with anatase than with rutile. For a suspension of rutile, the dependence upon frequency of ε' and ε'' is expressed precisely by the following relations, which have been given for insulating materials by Schweidler[2]:

$$\varepsilon' - \varepsilon \;\; = A \cot(\pi m/2)\omega^{-m} \qquad (1)$$

$$\varepsilon'' = A\omega^{-m} \qquad (2)$$

$$\varepsilon''/(\varepsilon' - \varepsilon_{\infty}) = \tan(\pi m/2) \qquad (3)$$

where ε_{∞} is the limiting value of ε' at high frequencies, A and m the empirical constants characteristic of the dispersed systems, and ω the angular frequency. Fig. 2 shows the linear relation between ε' and ε'' which can be expected from relation 3. In the case of anatase, the experimental results showed some deviation from these relations. Similar dielectric behaviour was observed also for a suspension of calcium carbonate powder.

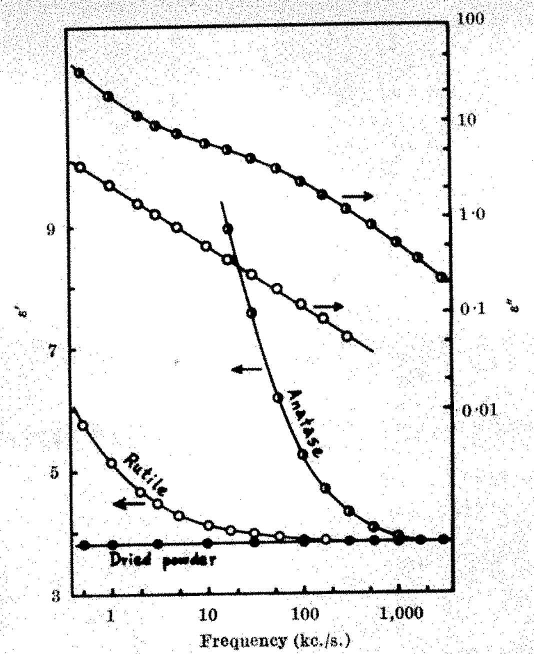

Fig. 1. Dependence upon frequency of ε' and ε'' for dispersed systems of titanium oxide (○ rutile, ◑ anatase and ● dried specimens) in liquid paraffin at 20° C. Particle size, moisture content and volume concentration of powders are about 0·4 micron, 0·7 per cent and 13 per cent respectively for both types of titanium oxide

However, this dependence upon frequency disappeared completely when the powder was dried at 150° C. for 3 hr., and the dielectric constant ε' remained constant over the range of frequency used, giving the value of ε_{∞} defined above, whereas ε'' was too small to be observed. Thus it is evident that the dielectric dispersion of the suspension mentioned above arises from the moisture adsorbed by the powder. This interfacial effect may be essentially the same as that pointed out for aqueous dispersions by Fricke.

In the cases of more hygroscopic powders, for example, starch and bentonite, the dependence upon frequency of ε' and ε'' was more complicated. It seems that, in these cases, anomalous dispersions of the type mentioned above and of the Debye type due to the polar groups overlap. The values of ε' for the powders of copper, aluminium and sulphur have been shown to be independent of the frequency even for air-dried specimens which contained

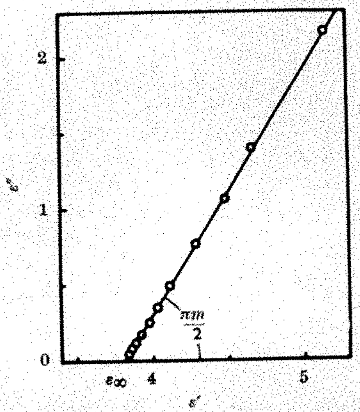

Fig. 2. Plots of ε'' versus ε' for the rutile suspension ; $m = 0·644$

appreciable moisture of more than 0·1 per cent by weight.

A more complete account of this work will be published elsewhere. We thank Prof. E. Suito and Prof. S. Ono for gifts of samples.

Electron Micrographs of a Crystalline Lattice Structure in Yolk Platelets of the Amphibian Embryo

YOLK platelets are one of the cytoplasmic inclusions characteristic of embryonic cells, and constitute the most important reserve material for these cells. A weak birefringence has been reported from fresh or fixed yolk platelets of various amphibian embryos[1]. However, no further information is available concerning the physical organization of these inclusions. In the course of our electron microscopic studies of embryonic cells, regular fringe systems have been found over the whole area of yolk platelets, indicating a crystalline structure of the yolk matrix.

Small pieces of the ectoderm were isolated from embryos of the newt, *Triturus pyrrhogaster*, at various stages[2] from the gastrula (stage 11) to the tail bud (stage 26). 1 per cent osmium tetroxide in Holtfreter solution buffered with veronal acetate at *p*H 7·8 was used as the fixative. After fixation at 4° C. for 2 hr. and subsequent washing in Holtfreter solution for a few minutes, the fixed material was dehydrated in a series of graded ethanols, and embedded in a mixture of methacrylates. Sections were made on an ultramicrotome at a thickness less than 50 mμ, picked up on a collodion-coated grid and examined with the Hitachi electron microscope *HU*–10 at 75 kV.

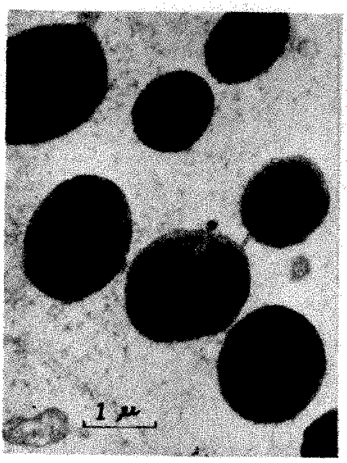

Fig. 1. Electron micrograph showing a group of yolk platelets scattered in the cytoplasm of an ectoderm cell of a late gastrula. One mitochondrion and the cell boundary are visible (below, left). × 10,000

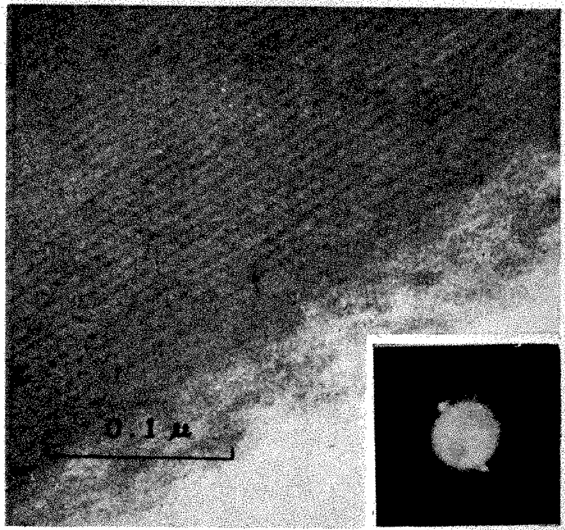

Fig. 2. High-power electron micrograph and selected area diffraction diagram (inset) of a yolk platelet. The granular layer attached to the surface of the yolk platelet is visible below in the main picture. Note the fringe system in the yolk platelet proper. × 250,000

In the embryonic ectoderm cells, the cytoplasm is moderately laden with yolk platelets. Under the electron microscope, the platelets appear as sharply outlined dark ovals varying from 0·3 to 6μ in diameter. The platelets are surrounded by a dense layer of fine granules of about 100 A. (Fig. 1). This layer disappears during the tail-bud stage, when significant changes take place on the surface of the yolk platelets[3].

Fig. 2 shows a high-magnification electron micrograph of the yolk platelets at the neurula stage, in which a system of fringes with spacing of 70 A. is evident. Careful observation reveals another system of weak fringes which is oblique to the main system. Similar fringe systems were observed in yolk platelets from the gastrula to the tail-bud stage. It should be noted that these fringes are always straight, and no dislocation has so far been observed in them. The regular arrangement of fringe systems proves that the matrix of yolk platelets is crystalline.

In the electron diffraction pattern of the yolk platelet, two pairs of spots can be observed (inset, Fig. 2). One pair is fairly strong and the other very weak. The presence of two pairs of spots would be expected from the existence of two systems of fringes intersecting each other in the electron micrograph. The distance between these spots corresponds to a fringe-spacing of 72 A. in both pairs. This spacing is in good agreement with that measured directly in the electron micrograph.

During the period of yolk resorption, the yolk platelets were found to split into parallel disks and rodlets[4]. A similar phenomenon of lamellar cleavage was observed also *in vitro* when the yolk platelets were exposed to weak acid or alkaline solutions[5]. These observations support the view that the crystalline structure seen in the fixed sections is not caused by the fixative but exists in the living cells.

We thank Profs. T. Yamada, R. Uyeda and Y. Sakaki for valuable suggestions, and the staff of the Hitachi Central Research Laboratory for generous assistance. The investigation was partly supported by grants from the Rockefeller Foundation to Prof. T. Yamada and the research funds of the Ministry of Education of Japan.

An Instrument for measuring Evaporation from Natural Surfaces

THE need has long existed for a direct method of measuring evaporation from natural surfaces for application in a wide range of problems connected with agricultural science, hydrological engineering and the like. The only method hitherto generally available has been that of isolating and weighing a portion of the evaporating body—a procedure which is cumbersome and often seriously interferes with the process it purports to measure. Reliance has therefore often been placed on formulæ, usually of doubtful validity, relating evaporation with other meteorological variables.

We have constructed prototype equipment which permits the automatic, direct determination of natural evaporation by equating it to the vertical turbulent flux of water vapour in the layers of air near the ground. The validity of this equation demands that there be no vertical transport of water vapour by mean vertical motion nor accumulation of water vapour between the ground, and the level of the instrument, and that a measurement of turbulent flux made at a point be representative of an area. Practically, this means that the area must be one of good horizontal uniformity and that the measurement must be made within a few metres of the ground. Providing that these conditions are fulfilled, there is no restriction on the nature of the surface. Measurements can then be made over, say, a growing crop or a free water surface with equal facility, and the method is directly applicable to problems such as those indicated above.

The turbulent flux of water vapour is given by the covariance between (1) the product of air density (ρ) and the vertical velocity component (w) and (2) the specific humidity (q). The principle involved was first used by Swinbank[1], who recorded fluctuations of ρw and of q and afterwards calculated the required covariance, $\overline{(\rho w)'q'}$ (where the primes indicate deviations from means and the bar an averaging with respect to time), at first by hand methods and later on a differential analyser. This method, though establishing the usefulness of the principle, is much too laborious for routine use.

The instrument which we have developed provides continuous electrical signals proportional to ρw and q, and performs the necessary mathematical operations of multiplication and integration automatically. Since the mean values of ρw and q cannot be known in advance, it is necessary to evaluate the required covariance in the form

$$\overline{(\rho w)'q'} = \overline{(\rho w - a)(q - b)} - \overline{(\rho w - a)}.\overline{(q - b)}$$

where a and b are arbitrary zeros from which ρw and q are measured. A block diagram of the instrumental arrangement is shown in Fig. 1.

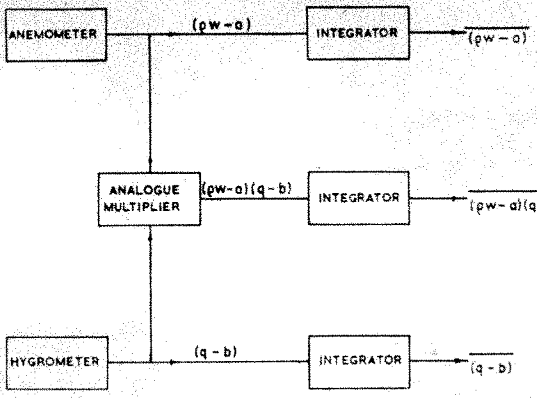

Fig. 1. Block diagram of evaporimeter

A height of 1·5 m. above the ground has been found suitable for mounting the sensing devices, and, at this height, response times of about 0·3 sec. are needed in the anemometer, hygrometer and multiplier in order to take account of the contribution to the flux made by the smallest eddies (1–2 sec. period) which are important at that height. A minimum period of observation of 5 min. is needed to accommodate the largest contributing eddies.

The anemometer, which is of an entirely new design[2], is linear and has a sufficiently rapid response. It depends in its operation on measuring the temperature in the wake of a heated wire by resistance-bridge thermometry and, by means of an amplifier feedback circuit controlling the input voltage to the bridge, this voltage can be made linearly dependent upon the product of ρ and the velocity component perpendicular to the instrument. Two such anemometers are arranged at equal and opposite angles to the horizontal, and the difference of their outputs is obtained as a measure of ρw.

The hygrometer is based on fine wire wet- and dry-bulb resistance thermometers of a design due to McIlroy[3]. These are constructed of fine nickel wire (0·0005 in. diam.) in order to obtain a sufficiently small response time, and are adjusted to a standard calibration of 900 ohms at 0° C. and 1,020 ohms at 30° C. A separate bridge network is used for each thermometer, the wet-bulb bridge being included in an electronic feedback circuit which simulates the saturated vapour pressure/temperature relationship of water[4]. The outputs of the two bridges are then combined in accordance with the psychrometric equation and an output signal linear with respect to $(q - b)$ is obtained.

Analogue multiplication is achieved by the quarter-square technique[5] making use of the identity $mn = \frac{1}{4}\{(m + n)^2 - (m - n)^2\}$. The squaring circuits each consist of a chain of ten diodes acting as function generators, four such chains being required for four-quadrant multiplication. Additions and subtractions are performed according to standard computing techniques using operational amplifiers.

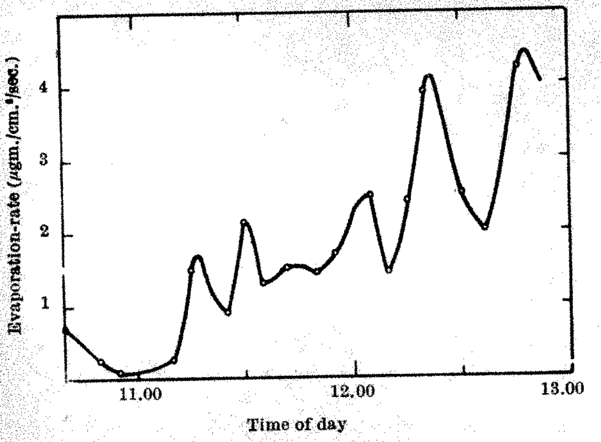

Fig. 2. Observed values of evaporation-rate, September 24, 1957

The integrators are of the electromagnetic type suggested by Gilbert[6], but with considerable modification of the original design to obtain greater accuracy and ruggedness. Special circuit arrangements have also been developed so that the integrator can accept currents of either sign. An important feature of this type of integrator in the present application is that it has no zero drift. A full description will be published by one of us (A. J. D.) elsewhere. The final results of the integrations appear on counters from which the total evaporation over the observation period is easily computed.

The complete equipment has been tested in the field, and some checks against Swinbank's method have been carried out with satisfactory results. A typical series of measurements is shown in Fig. 2, in which are plotted the results of a number of five minute runs. The increase in evaporation during the morning is evident, and the results demonstrate the inherent variability of the evaporation as a result of chance fluctuations in wind-speed, incoming radiation and other such factors.

Further field trials are now in progress, and development work is proceeding. Full instrumental details and the results of further observations will be published elsewhere.

Lamellar Compound of Sodium with Graphite

It is well known that graphite forms lamellar compounds with potassium, rubidium and cæsium[1,2], but hitherto it has seemed likely, both on experimental[1-3] and theoretical[4] grounds, that sodium does not behave in this way. Recent work at Harwell reported here has, however, provided evidence for the existence of a lamellar compound of sodium with graphite.

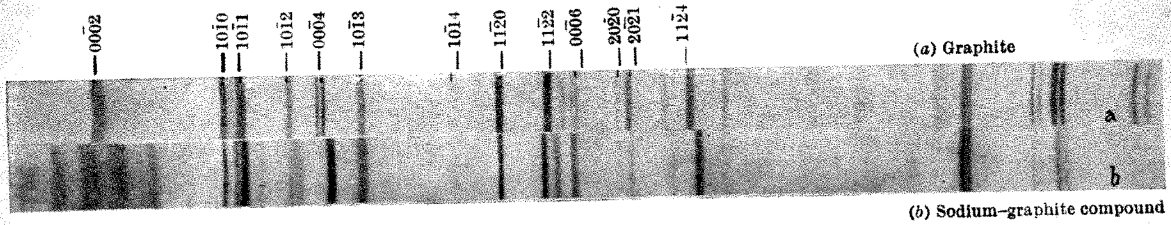
The compound was prepared very simply in a helium atmosphere (less than 20 p.p.m. oxygen) in a 'glove-box'. Powdered graphite was heated with about 3 per cent sodium (commercial purity, filtered through sintered glass at about 150° C.) at about 400° C. for 1 hr. with continuous stirring. The conditions are not at all critical, since the compound has been formed with heating times between ½ hr. and 6 hr. and at temperatures between 120° and 500° C. (although mixing is bad below about 200° C.). The product, virtually pure sodium-graphite compound, is very similar in appearance to the parent graphite but has a deep violet tinge. The analogous potassium, rubidium and cæsium compounds have similar strong colours; for example, C_8K is copper-coloured.

The main evidence for the formation of a compound is obtained from X-ray diffraction (compare the typical photographs in Fig. 1,*a* and *b*). We have found that the product made from a highly crystalline graphite, such as purified natural graphite, gives the most sharply defined X-ray diffraction pattern, but that the same product is formed from less-crystalline materials, for example, reactor-grade graphite; the definition is also improved by prolonged heating at about 400° C.

The formation of a compound is indicated in two ways. First, several diffraction lines which are strongly characteristic of graphite (for example, the $00\bar{0}2$ and $00\bar{0}4$ lines) are absent from the diffraction photograph of the product; as little as 5 per cent free graphite should be detectable in this way. Secondly, the product has a definite composition. Thus if excess of either sodium or graphite was used in the preparation, the excess was revealed roughly quantitatively in the photograph as unreacted material. The composition was found by this method to be between $C_{60}Na$ and $C_{68}Na$—probably $C_{64}Na$.

The change in structure thus indicated cannot be attributed to the formation of the potassium-graphite compounds since the potassium content of the sodium was certainly less than 0·1 per cent.

These diffraction results seem to fit best a structure in which sodium atoms lie in interstitial planes separated by eight carbon layers (that is, a lamellar compound) as indicated in Fig. 2,*a*. At every eighth layer, therefore, the spacing is increased in this way from 3·35 A. to about 4·6 A., which is consistent with



(*a*) Graphite

(*b*) Sodium–graphite compound

Fig. 1

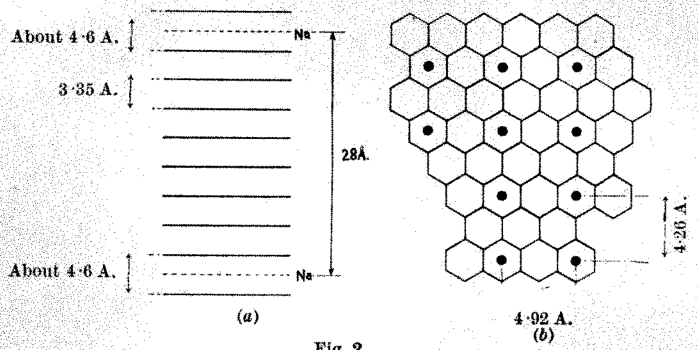


Fig. 2

the atomic diameters of sodium and carbon. The unit-cell dimension in the c direction then becomes 28 A. (or a simple multiple of this) and the average layer spacing is now 3·50 A., that is, 5 per cent greater than in the parent graphite. Graphite artefacts swell when immersed in liquid sodium, but only by about 0·5–1·0 per cent. The smaller magnitude of this swelling compared with the increase in the c spacing is due mainly to the fact that the crystallites in an artefact are anisotropically oriented. Since it is possible to estimate the degree of this anisotropy from the thermal expansion, we have been able to relate, at least approximately, the swelling to the change in the c spacing.

The detailed analysis of the X-ray photographs is not yet complete. At present, therefore, it is possible to make only a tentative suggestion for the arrangement of the sodium atoms within the interlayer gaps. That indicated in Fig. 2,b would account for the formula $C_{64}Na$.

The compound with the suggested formula $C_{64}Na$ is the only sodium-graphite compound which has been detected in our work in spite of the range of experimental conditions used. Thus sodium apparently differs from the heavier alkali metals; potassium, for example, is reported[2] to form a range of compounds between C_8K and $C_{60}K$.

Fuller reports, including the results of the more detailed structural analysis and also measurements of the physical effects of sodium on graphite, will be published elsewhere.

Ferric Perchlorate Complex Ion

Sutton[1], and later Sykes[2], have reported association constants for the formation of ferric perchlorate complex ion, $FeClO_4^{++}$, although other investigators have been unable to find evidence for the existence of this species[3,4]. Inasmuch as perchloric acid and perchlorate salts are commonly used for maintaining constant ionic strength in physical-chemical measurements on the assumption that perchlorate ion does not complex appreciably with cations in aqueous solution, the question of the existence and extent of perchlorate complexing is a matter of some importance.

Both Sutton[1] and Myers[5] have suggested that perchlorate complexing might play a part in the kinetics of the iron(II)–iron(III) electron-exchange reaction. For reaction paths involving hydrated but otherwise uncomplexed ferrous ion and ferric species the rate of this exchange reaction, generalizing the results of Silverman and Dodson[6], may be represented by

$$R = \sum_{X} \sum_{n=0}^{n=6} k_n\, (\mathrm{Fe}X_n^{3-mn})\, (\mathrm{Fe}^{++}) \qquad (1)$$

where R is the rate of exchange, X is any complexing ligand (including hydroxide ion) of charge m, and k_n is the specific reaction-rate constant for the exchange process in which Fe^{++} and $\mathrm{Fe}X_n^{3-mn}$ are reactants. Silverman and Dodson[6] and Hudis and Wahl[7] have assumed that k_0, the specific reaction-rate constant for the exchange process involving uncomplexed ferric ion, has a value other than zero, that is to say, that exchange occurs between ferrous and uncomplexed ferric ion. Experiments which substitute heavy water for water as solvent[8], however, indicate that the situation is more complicated than initially supposed.

Alternatively, if k_0 is nearly zero, and if $FeClO_4^{++}$ is the only ferric perchlorate complex formed, assuming a value for k_1, the specific reaction-rate constant for the exchange process involving $FeClO_4^{++}$ on the basis of the values for other monovalent complexing anions, the value of the formation constant, K_1, for the ferric monoperchlorate complex ion can be estimated from available kinetic data on the exchange reaction since,

$$(\mathrm{Fe}X_n^{3-mn}) = K_n\, (\mathrm{Fe}^{+++})\, (X)^n \qquad (2)$$

and the rate contributions of hydrolysed ferric species are known. According to the data of Silverman and Dodson[6], at 21·6° C. and an ionic strength of 0·55:

$$k_1 K_1 = k/(\mathrm{ClO}_4^-) = 3\cdot3/0\cdot55 = 6\cdot0 \text{ sec.}^{-1}\text{ f.}^{-2} \qquad (3)$$

where k is a specific reaction-rate constant determined by Silverman and Dodson and equated by them to k_0. Except for $FeOH^{++}$, the reactions of ferrous ion with dipositive ferric complexes have specific rate constants of comparable magnitude and apparently related to the size of the complexing anion. If the value of k_1 is estimated to be between 1 and 10 sec.$^{-1}$ f.$^{-1}$ by analogy with the values of 14, 20, 29 and 40 sec.$^{-1}$ f.$^{-1}$ for bromide[9], thiocyanate[9], chloride[6] and fluoride[7] ions respectively, then the resulting formation constant for the ferric monoperchlorate complex ion is between 6 and 0·6 f.$^{-1}$. The values reported by Sykes[2] on the basis of his own studies and calculated by him from data of others and from Bjerrum's theory, corrected to an ionic strength of 0·55 using the semi-empirical equation[3] and ignoring small temperature differences, namely, 2·8, 2·0 and 4·4 f.$^{-1}$ respectively, all lie well within these limits.

This work was performed under the auspices of the U.S. Atomic Energy Commission.

Differential Thermal Method for determining Reactivity of Calcium Oxide

It has been reported[1] that the extent to which the reaction

$$CaO + MgCO_3 \rightarrow CaCO_3 + MgO$$

proceeds is influenced by the reactivity of the calcium oxide. The possibility that both this and the analogous reaction

$$CaO + Mg(OH)_2 \rightarrow Ca(OH)_2 + MgO$$

might be used for determining the reactivity of calcium oxide was systematically investigated, using differential thermal analysis. A hydration calorimetric technique and determinations of specific surface area by nitrogen adsorption were used for comparative purposes.

On the basis of the established fact that the reactivity of calcium oxide decreases as the temperature of calcination increases[2], samples of calcium oxide of widely differing reactivity were prepared by heating reagent quality calcium hydroxide at 100 deg. C. temperature intervals over the range 500–1,400° C. and precipitated calcium carbonate over the range 900–1,400° C. Thermograms for mixes of equimolecular quantities of such calcium oxides and magnesite are presented in Fig. 1 as curves (*a*) to (*e*) inclusive. Only one curve, (*e*), is given for the oxide from the carbonate because the curves were virtually identical for all such oxides prepared. The thermograms for the mixtures containing calcium oxide derived from calcium hydroxide at temperatures up to 1,100° C. show an exothermic peak at about 380° C., due to the net exothermal effect of the reaction. The subsequent endotherms represent respectively the decomposition of the remaining magnesite and the calcium carbonate formed as a result of the interchange reaction. The fact that, for the comparatively inactive forms of oxide where no interchange exotherm was found, considerable amounts of calcium carbonate were nevertheless formed, shows that its formation also proceeds as a result of reaction between the calcium oxide and the carbon dioxide formed during the magnesite decomposition over the range 600–700° C.

Three trends can be seen from these results. First, as the reactivity of the calcium oxide decreases, so the extent of the exothermal interchange reaction decreases until, for the oxide obtained from calcium hydroxide at 1,200° C. or higher, and for all oxide obtained from calcium carbonate, it is absent. Secondly, the area of the magnesite peak increases as the reactivity of the oxide decreases, and thirdly, the calcium carbonate peak area shows a corresponding decrease. The relationship between the oxide reactivity as reflected by the ratio of thermoactive reaction product and reactant peak areas and its temperature of preparation is presented in Fig. 2 in curves (*a*) and (a_1) respectively for the oxide obtained from the hydroxide and the carbonate.

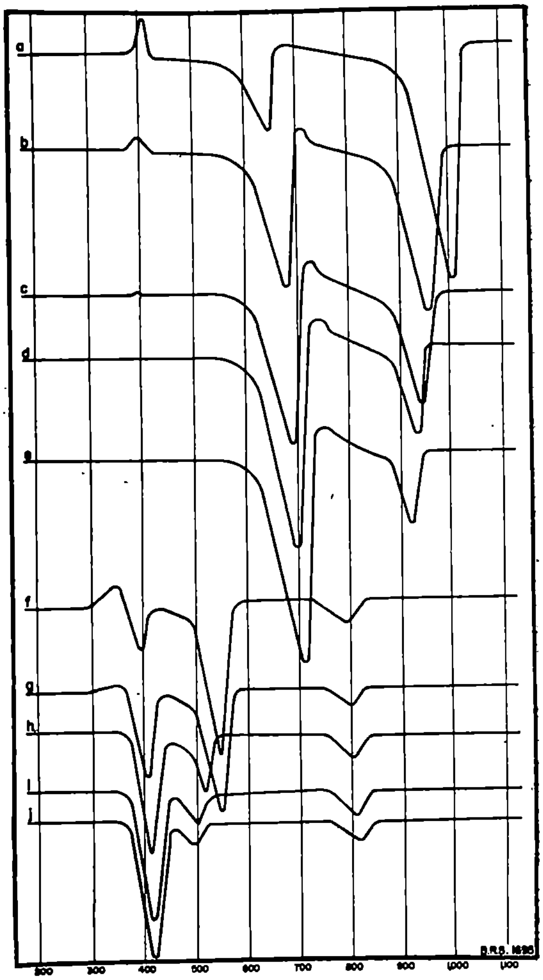

Fig. 1. Thermograms for equimolecular mixtures of magnesite or magnesium hydroxide and calcium oxide of origin indicated: (*a*)–(*d*), Magnesite and CaO derived from Ca(OH$_2$) at (*a*) 500° C., (*b*) 900° C., (*c*) 1,100° C., (*d*) 1,400° C.; (*e*), magnesite + CaO derived from $CaCO_3$ at 900° C.; (*f*)–(*i*), magnesium hydroxide + CaO derived from Ca(OH$_2$) at (*f*) 500° C., (*g*) 900° C., (*h*) 1,100° C., (*i*) 1,400° C.; (*j*), magnesium hydroxide + CaO derived from $CaCO_3$ at 900° C.

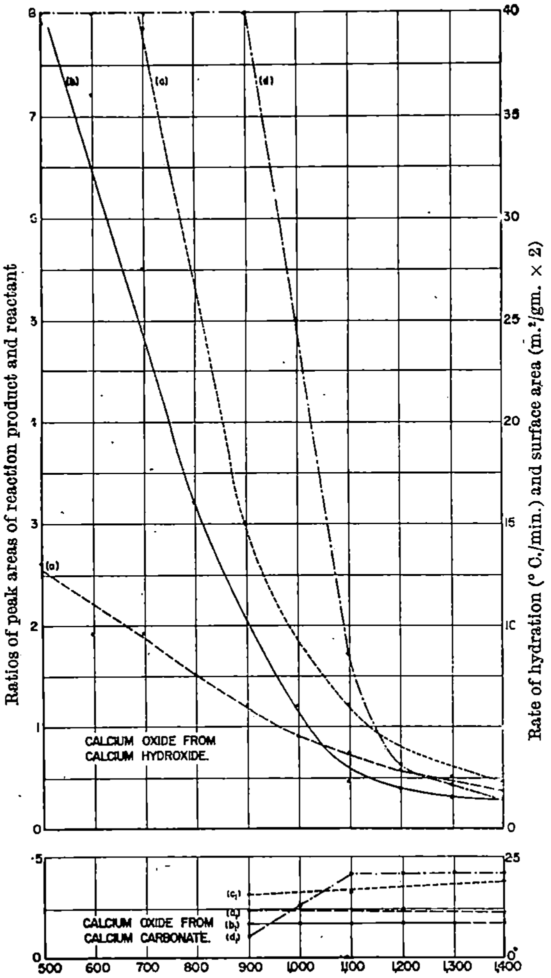
Thermograms for the magnesium hydroxide–calcium oxide mixes are shown in Fig. 1 as curves (*f*)–(*j*) inclusive. For the most reactive oxides the exothermal peak above 300° C. is evident; as the oxide reactivity and the extent of reaction decreases, the subsequent magnesium hydroxide peak increases and the calcium hydroxide reaction product peak decreases. From the peak area ratios illustrated in Fig. 2, curves (*a*), (a_1), (*b*) and (b_1) the parallel trends of the results for the two reactions investigated are evident; the results of the specific surface area determinations (curves (*c*) and (c_1)) and the hydration



Temperature of preparation of calcium oxide (° C.)

Fig. 2. Effect of origin and temperature of preparation of calcium oxide on ratio of peak areas of reaction product and reactant for magnesite–calcium oxide reaction (— — —), and magnesium hydroxide–calcium oxide reaction (———); on surface area (------) and on rate of hydration (—·—·—·—) of the calcium oxide

calorimetric data (curves (*d*) and (d_1)) demonstrate that these latter-established techniques yielded somewhat similar results. The decrease in the reactivity of the oxide obtained from calcium hydroxide with increasing calcination temperature and the virtual independence of reactivity on calcination temperature for that prepared from precipitated calcium carbonate emerge clearly. However, by these techniques of differential thermal analysis, the reactivity of calcium oxide prepared from calcite was found to decrease with increasing calcination temperature, as reported by Murray, Fischer and Sabean[3] and others.

While the hydration calorimetric technique shows marked differences in the reactivity of the oxide from calcium hydroxide calcined over the range 900–1,400° C., it does not, under the experimental conditions used, discriminate between oxides of widely differing reactivity prepared over the range 500–900° C.; differential thermal analysis, for both reactions, shows marked differences of reactivity for oxide prepared in the range 700–1,100° C. for the exothermic reactions and over the wider range 500–1,400° C. for the reaction product–reactant peak area ratio.

Slight hydration of the calcium oxide, corresponding to an ignition loss of about 5 per cent, profoundly reduced its reactivity as evaluated by the hydration calorimetric technique. In contrast, with the technique of differential thermal analysis, hydration of calcium oxide does not reduce the measured reactivity.

Action of Periodate on some Polysaccharides containing Aldoheptose Sugars

Information about the molecular localities of the heptose residues in certain polysaccharides[1] may be obtained by application, in sequence, of periodate oxidation, reduction with sodium borohydride and acidic hydrolysis.

The following experimental procedure was adopted: aqueous solutions of polysaccharide (1 vol., 1 per cent w/v) and sodium metaperiodate (0·5 vol., 2 per cent w/v) were mixed at room temperature (*c.* 20°). At suitable time-intervals, aliquots (2 ml.) were withdrawn and treated immediately with ethylene glycol (0·5 ml.). After standing for 15 min. a fresh aqueous solution of sodium borohydride (2 ml., 1 per cent w/v) was added. After a further 15-min. period glacial acetic acid (1 ml.) was added to each aliquot, which was diluted to 8 ml., dialysed overnight against running tap-water and freeze dried. Samples of these products were used for aldoheptose and hexose determination by the Dische methods[2], further samples of 3–10 mgm. were hydrolysed in ampoules with 2 *N* hydrochloric acid (0·5 ml.) at 100° for 3 hr., the hydrolysates diluted to 5 ml. and neutralized by di-*n*-octylmethylamine[3]. The hydrolysates were freed from amino-sugars by 'Amberlite *IR*-120' (H+), neutralized[3], concentrated and analysed by zone electrophoresis (enclosed strip method[4], borate buffer *p*H 10) and paper chromatography[5]. The results are summarized in Fig. 1 and Table 1.

The heptose content of the *Chromobacterium violaceum* polysaccharides was rapidly reduced by 90 per cent or more whereas about 30 per cent of that of *Pasteurella pestis* polysaccharide remained intact (Fig. 1) and could be detected by paper chromatographic and zone electrophoretic analysis (Table 1). There was a corresponding increase in the hexose content in the initial stage of the reaction.

Thus in the polysaccharides studied it appears that there may be at least two modes of linkage of the heptose units, in one of which the heptose is very rapidly attacked by periodate.

Table 1. CHANGE IN NITROGEN-FREE SUGAR CONTENT OF SOME BACTERIAL POLYSACCHARIDES ON PERIODATE OXIDATION FOLLOWED BY REDUCTION

Polysaccharide source	Time of periodate oxidation (min.)	Glucose	Galactose	Mannose	Rhamnose	D-Glycero-D-galactoheptose	D-Glycero D-mannoheptose	L-Glycero-D-mannoheptose
*Pasteurella pestis** (ref. 6)	0	++		−				+++
	1–2	++		++				++
	4–8	++		++				++
Chromobacterium violaceum N.C.T.C. 7917 (ref. 7)†	0	+	+++	−			++	
	2	+	+++	++			+	
	4–8	+	+++	++			−	
C. violaceum (BN)* (ref. 8)	0		−		++	+++		
	8		+++		++	−		

+++, Major component; ++, moderate amount; +, trace; −, not detected.
* Also contains *N*-acetyl-D-glucosamine.
† Also contains *N*-acetyl-D-fucosamine.

In the reaction sequence adopted the heptose was converted to a hexose which, in each instance, was different from that originally present in the polysaccharide (Table 1) and, moreover, was that anticipated from the structures allocated (only tentatively for *P. pestis* and *C. violaceum* 7917) to the parent heptoses.

A possible structural arrangement which would account for the above observations would involve the presence of heptopyranose units with unsubstituted $C_{(6)}$- and $C_{(7)}$-hydroxyl groups, as terminal or internal units in the polysaccharide chains.

Conversion of the heptose units in the polysaccharides to hexose units may offer a means of simplifying structural determination of the polymers.

An attempt to relate the structural changes induced to loss of serological specificity could only be attempted with the *C. violaceum* (7917) polysaccharide. Serological activity was tested by inhibition of hæmagglutination using red cells sensitized with the parent lipopolysaccharide[9]. In this instance all serological activity appeared to have been lost after exposure to periodate for 30 sec.; reduction with sodium borohydride alone, however, caused no detectable loss of serological activity. This agrees with the widely held view that the reducing end residue does not contribute significantly to the serological specificity.

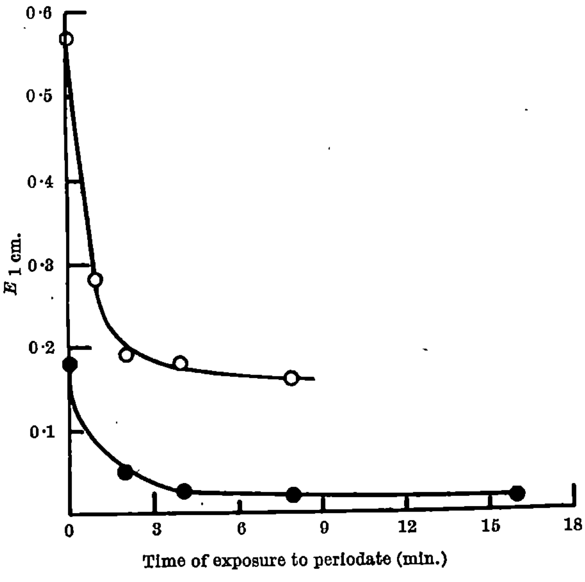

Fig. 1. Loss of aldoheptose sugars from bacterial polysaccharides on periodate oxidation. Heptose estimated colorimetrically (ref. 2) and expressed as extinction 505–540 mμ. ○, *P. pestis* polysaccharide; ●, *C. violaceum* (7917) polysaccharide; the identity of the heptose sugars has not been rigorously established, but they are believed to be L-glycero-D-mannoheptose and D-glycero-D-mannoheptose respectively

Formation of >C=O Bonds in the Radiation-induced Oxidation of Protein in Aqueous Systems

A SERIES of observations recently made indicate that formation of the >C=O bond is a principal chemical effect of the attack of hydroxyl radicals on protein in oxygenated solution. Irradiations were made in a neutron flux produced by bombardment of beryllium with 24-MeV. deuterons in the Crocker Laboratory 60-in. cyclotron. Solutions were exposed under one atmosphere of oxygen in sealed 'Pyrex' cells mounted in a motor-driven reel situated 15 cm. from the beryllium target. One of the cells in each exposure contained a formic acid–oxygen dosimeter[1]. (We employed the formic acid–oxygen dosimeter to obtain an estimate of the relative number of water molecules decomposed via (1) $H_2O = H + OH$ and (2) $H_2O = \frac{1}{2}H_2 + \frac{1}{2}H_2O_2$. Absolute yield values could then be calculated in terms of G(molecules/100 eV.), since in dilute solutions at pH values above 2·5, the sum $G(1) + G(2) = G(H_2O)$ is to a first approximation independent of the quality of the absorbed radiation[1]. With our standard geometry for neutron exposures, we obtained $G(1) = 2{\cdot}68$, $G(2) = 0{\cdot}97$ on the basis of $G(H_2O) = 3{\cdot}65$[2].)

The following procedures were found applicable to the study of carbonyl formation in aqueous pepsin (twice crystallized, Lot No. 9477 Nutritional Biochemicals Corporation, Cleveland, Ohio) solutions (6·0 mgm./ml., 0·5 M in sodium sulphate, 10^{-3} M in sulphuric acid)[3]. Immediately after irradiation, platinum black was added to destroy hydrogen peroxide, and the solution was heated to obtain the two fractions, precipitate (I) and supernatant (II). Each was treated with 2,4-dinitrophenylhydrazine–hydrochloric acid solution[4] and dialysed to remove excess reagent and any products of low molecular weight. An appropriate aliquot of the dialysed protein was then added to methanol–potassium hydroxide solution for spectrophotometric analysis after the method of Lappin and Clark[5]. These authors have shown for monocarbonyl 2,4-dinitrophenylhydrazones that the position of the absorption maximum, as well as the value $E_{\text{max.}}$, is nearly independent of the structure of the carbonyl compound. We found that the absorption spectrum of fraction I ($E_{\text{max.}} = 480$ mμ) corresponded to the spectrum of authentic monocarbonyl hydrazones and, by using the formaldehyde derivative as a standard, obtained the value[3] $G = 1{\cdot}2$ for monocarbonyl production at a dose equivalent to $2{\cdot}5 \times 10^{18}$ eV./ml. Fraction II showed a blue colour and absorption spectrum ($E_{\text{max.}} = 550$ mμ) which can be attributed to 1,2-dicarbonylhydrazones. Using an authentic glyoxal derivative as a standard, we obtained $G = 0{\cdot}02$ for dicarbonyl production. The pepsin in unirradiated control solutions showed no retention of 2,4-dinitrophenylhydrazine. The position of carbonyl formation in the radiation-induced oxidation of pepsin is now under investigation; the relative importance of the various main and/or side-chain bonds is being determined.

Independent evidence for formation of carbonyl groups through processes induced by attack of hydroxyl radicals at the peptide linkage has been obtained in a parallel study of the oxidation of gelatin (purified pigskin, Lot No. 60–6657, Eastman Organic Chemicals solution) (40 mgm./ml. in air-saturated solution) by Fenton's reagent in which case hydroxyl radicals are formed by the reaction[6] $Fe^{2+} + H_2O_2 = Fe^{3+} + OH^- + OH$. We have found in this system (*a*) that the dialysed protein contains approximately one carbonyl group for every two hydroxyl radicals formed and (*b*) that glyoxylic, pyruvic, and α-ketoglutaric acids are among the carbonyl compounds liberated on hydrolysis of the dialysed fraction with 2 *N* hydrochloric acid solution under oxygen-free conditions. Identification of the keto-acids is based on the observation that the 2,4-dinitrophenylhydrazone derivatives could not be distinguished chromatographically[7] from the corresponding authentic material. (Formation of these keto acids is consistent with a previously suggested mechanism for the radiation-induced rupture of the peptide linkage[8]; $R\text{CONHC}R_2 \rightarrow R\text{CON}{=\!=}\text{C}R_2 \xrightarrow{H_2O} R\text{CONH}_2 + R_2\text{CO}$. We have recently found that irradiated solid pepsin on dissolution in water also yields high-molecular-weight products containing carbonyl groups and suggest that imino intermediates are also involved in direct action: $R\text{CONHC}R_2 \rightarrow R\text{CON}{=\!=}\text{C}R_2 + H_2$.)

The possible biological importance of carbonyl formation is indicated by the observation that the addition of 2,4-dinitrophenylhydrazine to irradiated (4×10^{17} eV./ml.) rat liver homogenate[9] (50 mgm./ml. in water) gave a non-dialysable hydrazone fraction that exhibited an intense magenta colour on mixing with methanol–potassium hydroxide. (We estimate that this technique, with slight modification, could be used for measuring an X-ray dose of a few hundred roentgens.) Control tests with unirradiated homogenate showed a negligible background colour. The literature[10] indicates that radiation-induced oxidation of a number of different types of chemical linkages may contribute to carbonyl production in a biological system.

A detailed report of this work will appear in a forthcoming paper.

This work was performed under the auspices of the U.S. Atomic Energy Commission.

Acetylation of Trypsin in Organic Solvents

PREVIOUS work in this laboratory has shown that treatment of trypsin with various anhydrides results in the formation of the corresponding acyltrypsin derivatives, each possessing some interesting properties of its own, while all retained their original proteolytic activity[1]. From the derivatives so far prepared, acetyltrypsin is the best-characterized chemically modified enzyme[2], while succinyltrypsin is the most stable of the derivatives so far obtained[3]. The use of water as a solvent in investigating enzyme modification sets some definite limitations as to type of reagent usable and as to reactions possible. It was with these experiences in mind that the study of acetylation of trypsin was pursued in two organic solvents, formamide and dimethylsulphoxide, Rees and Singer[4] having indicated the compatibility of these systems.

The dissolution of trypsin in the two solvents results in an immediate loss of about 50 per cent of the enzymic activity, when it is assayed in the conventional way, that is, in aqueous solutions, using either urea-denatured hæmoglobin or benzoylarginine ethyl ester as substrates. On prolonged incubation in the two solvents, no further decrease in activity is observed. The loss in activity is not diminished by distilling formamide twice over calcium or barium oxide, at a pressure of 1 mm. Effective purification can be, however, obtained by treatment of the solvent with a cation exchange resin ('Amberlite *IR*–120'). By this manipulation, more than 85 per cent of the tryptic activity is retained. The addition to the solvent of minute amounts of acetic or citric acids, acetyltryptophan and hydrochloride of benzoylarginine ethyl ester also results in the stabilization of the enzyme. The addition of alkali destroys proportionately tryptic activity, while the temperature at which the experiments are carried out is without noticeable effect. The dissolution of trypsin in organic solvent–water mixtures with increasing water content does not stabilize the enzyme. On the contrary, there is a relatively narrow region containing about 55–65 per

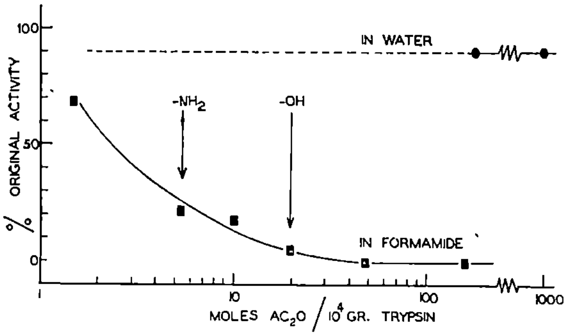

Fig. 1. Inactivation of trypsin by acetic anhydride in formamide. Trypsin concentration: 5 mgm./ml. of formamide; acetylation for 1 hr. at 22° C. Two stoichiometric points are indicated, corresponding to the total number of amino- and hydroxyl-groups present in trypsin

cent of organic solvent, in which the enzyme loses up to 80 per cent of its activity on dissolution in 'Amberlite'-untreated formamide. In treated formamide, or dimethylsulphoxide, this is not observed.

The acetylation of trypsin in the two solvents is accompanied by a loss of enzymic activity in proportion to the amount of anhydride employed. While in buffered aqueous solutions huge excesses of the anhydride are without detrimental effect, a total loss of activity is observed in formamide, at 22° C., when about 50 equivalents of anhydride are employed per mole of trypsin. This amount corresponds approximately to the total number of hydroxyl groups in trypsin. The correlation of activity and amount of anhydride is recorded in Fig. 1.

The extent of substitution of amino- and hydroxyl-groups in trypsin, acetylated with an amount of anhydride corresponding to the total hydroxyl groups of the enzyme, was found to be 95 per cent and 7·5 per cent respectively. This proportion is essentially identical with that observed in the course of acetylation of the enzyme in aqueous solutions[2]. Therefore, the degree of substitution by itself does not explain the loss in activity. At higher proportions of anhydride, a complete acetylation of the hydroxyl groups occurs in formamide, but not in water. It would therefore appear that the difference in specificity of the reaction is responsible for the inactivation of the enzyme. The inactivation is irreversible, and activity cannot be regained by mild hydrolytic treatment.

This study was carried out under the auspices of the U.S. Atomic Energy Commission.

Carotenoid-sensitized Fluorescence of Chlorophyll *in vitro*

It is well established that light absorbed by carotenoids can contribute to photosynthesis, phototaxis and the red fluorescence shown by chlorophyll *A* in the intact chloroplast. In *Chlorella*, independent measurements of both fluorescence[1] and photosynthesis[2] indicate a 40–50 per cent efficiency of energy transfer from β-carotene and lutein to chlorophyll *A*. In brown algae[3,4] almost complete transfer of energy from fucoxanthol to chlorophyll *A* is reported.

Table 1

Carotenoid		Porphin	Approximate transfer efficiency (per cent)
β-Carotene	transfer to	Chlorophyll *A*	10
,,	,, ,,	Phæophytin *A*	0
Lutein	,, ,,	Chlorophyll *A*	60
,,	,, ,,	Chlorophyll *B*	10
,,	,, ,,	Phæophytin *A*	0
Fucoxanthol	,, ,,	Chlorophyll *A*	100
,,	,, ,,	Chlorophyll *B*	20
,,	,, ,,	Phæophytin	0

This transfer has now been observed in artificial systems, in which the concentration of pigments approaches that found in chloroplasts. Pure plant pigments, freshly prepared by chromatography, were dispersed in detergent micelles[5] to give local concentrations of about 0·1 *M*. In this way, equimolecular mixtures of carotenoid and chlorophyll or phæophytin were prepared. Electronic energy transfer was measured by comparing the fluorescence excitation spectra of chlorophyll or phæophytin in the presence and absence of carotenoid. The exciting wave-lengths ranged between 380 and 670 mμ. Two of the resulting spectra are shown in Fig. 1, together with the difference spectra representing the contribution of fucoxanthol and lutein respectively to chlorophyll *A* fluorescence. Table 1 shows approximate transfer efficiencies for several pairs of pigments all at roughly 0·1 *M* concentration.

These results show that for lutein and fucoxanthol, transfer to chlorophyll *A* in micelles is similar in

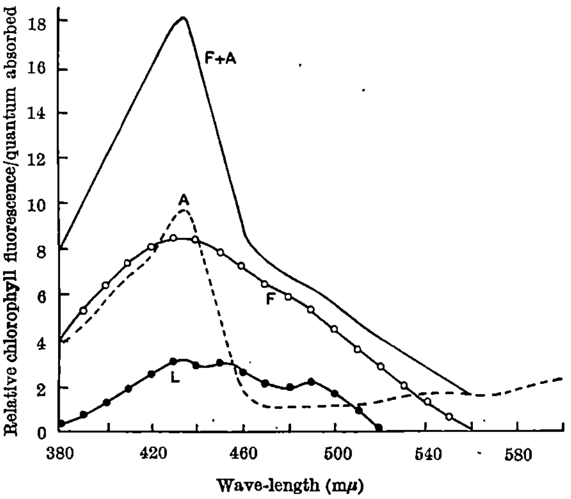

Fig. 1. Electronic energy transfer from carotenoids to chlorophyll *A* in detergent micelles. *A* and *F* + *A*, Fluorescence excitation spectra of chlorophyll *A* alone, and an equimolecular mixture of *F*, fucoxanthol and chlorophyll *A*; *F* and *L*, difference spectra measuring electronic energy transfer from fucoxanthol and lutein respectively to chlorophyll *A*. Ordinate: Relative numbers of quanta absorbed which appear as chlorophyll *A* fluorescence; abscissa, wave-length of exciting light in mμ

magnitude to that reported for chloroplasts. The value for β-carotene may be too low, as difficulty was encountered in dispersing this material in micelles.

The low value for carotenoid–chlorophyll *B* transfer, and zero transfer to phæophytin *A* are surprising, if only the intermolecular distance and estimated overlap of absorption and emission spectra are considered. These are similar for both the chlorophylls and phæophytin *A*. It is evident[6], however, that proximity and overlap are not the only factors necessary for transfer. The ratio of the fluorescence polarization measured with radiation absorbed mainly by fucoxanthol, to that excited by radiation absorbed only by the red band of chlorophyll *A*, was determined. In chlorophyll *A* alone this ratio is 23 per cent, while in the fucoxanthol–chlorophyll *A* system this value is increased to 70 per cent. This increase in positive polarization illustrates the preferred coupling of fluorescence and absorption oscillators which the transfer involves. High positive polarizations are only found in chlorophyll *A* beyond 600 mμ.[7], so that the fluorescence spectrum of fucoxanthol presumably extends into this region.

It is tempting, in view of the high efficiency of transfer to chlorophyll *A* compared with chlorophyll *B* and phæophytin *A*, to assume a specific complex to exist.

However, an approximate calculation indicates that the observed transfer values could exist in a random array of pigment molecules. By an absolute method[8], the carotenoids can be shown to have quantum yields not greater than 10^{-4}. If this value is taken as a maximum value, the fluorescence lifetime must be of the order of 10^{-12} sec. For a normal lifetime of 10^{-8} sec. we can assume a half-transfer radius of about 40 A., taking into account the overlap integral and the transfer radii reported for xanthydrol dye molecules[9]. Assuming transfer by the mechanism of coupled oscillators, *d* the half-transfer radius for a fluorescence lifetime of 10^{-12} sec. is given by

$$\left[\frac{40}{d}\right]^6 = \frac{10^{-8}}{10^{-12}} \text{ or } d = 8{\cdot}6 \text{ A.}$$

In an equimolar mixture of pigments at 0·1 *M* concentration the average intermolecular spacing *d* is 10 A., while many intermolecular distances will be smaller. The higher efficiency of fucoxanthol compared with lutein could be due to higher absolute quantum yield, or a more efficient overlap of its fluorescence spectrum with chlorophyll *A* absorption.

Complex formation usually produces changes in position of absorption maxima. No such changes, however, were observed in the systems showing transfer. Carotenoids, on the other hand, show very marked flattening and broadening of the absorption bands. Fucoxanthol and lutein, which in dilute solutions do not absorb beyond about 500 mμ, show absorption up to 560 mμ and 520 mμ respectively. Similar broadening can be seen in concentrated solutions of the pure carotenoids. The extension of fucoxanthol absorption to about 560 mμ is observed in brown algae and is responsible for their characteristic colour. When the grana are disintegrated by heating, the algae become green, as the absorption limit of fucoxanthol returns to about 500 mμ.

In brown algae, fucoxanthol is an efficient substitute for chlorophyll *B*, filling in the region 460–540 mμ where chlorophyll *A* is relatively transparent, and in these plants the fucoxanthol–chlorophyll *A* ratio approaches unity. In green plants however, where the fractional absorption of carotenoids is small, it is probable the energy transfer is only a manifestation of the proximity of these pigment molecules, the full significance of which remains to be determined.

Effects of Orotic Acid on Coenzyme A and Pantothenic Acid of Liver in Vitamin B_{12} Deficiency

OROTIC ACID was found to reduce the vitamin B_{12} requirement for growth and for the betaine–homocysteine transmethylase activity of liver in rats fed corn/soybean meal ration deficient in vitamin B_{12}[1]. These results suggested a metabolic relationship between orotic acid and vitamin B_{12}. To ascertain whether this metabolic relationship was limited or more extended, we have directed our research towards other biochemical modifications reported in vitamin B_{12} deficiency.

Since an increase in concentration of liver pantothenic acid[2] and coenzyme A[3] was observed in animals deficient in vitamin B_{12}, we have extended our investigation to the effect of orotic acid on content of total pantothenic acid and coenzyme A of liver in rats deficient in vitamin B_{12}.

To this end, fifteen weanling male rats of the Sprague–Dawley strain, weighing 40–45 gm., were employed. The animals were divided into three groups, all of which were fed the basal corn/soybean meal ration deficient in vitamin B_{12} as proposed by Register *et al.*[4]. Iodinated casein or desiccated thyroid was omitted. Group 1 served as control and received only the basal ration. Group 2 was fed the basal ration supplemented with vitamin B_{12} (2γ/100 gm. of diet). Group 3 received the basal ration supplemented with orotic acid (1,000γ/100 gm. of diet). The animals were maintained on their respective ration for 8 weeks and weighed weekly. Feed and water were supplied *ad libitum*. At the end of the experiment the animals were killed by decapitation and bled. Total pantothenic acid and coenzyme A were evaluated in the liver of each animal. To liberate pantothenic acid from liver tissues, a weighed portion of each liver was homogenized in a Potter glass-homogenizer with four volumes of water. 2 ml. of this homogenate were placed in a 125 ml. Erlenmeyer flask with 40 ml. of water and 1 ml. of toluene. The materials were incubated for 16 hr. at 37° C. After incubation the samples were boiled, cooled, adjusted to 100 ml. and filtered. Total pantothenic acid was assayed, according to the method of Skeggs and Wright[5], in aliquots of the filtrate, utilizing *L. arabinosus* 17/5 *ATCC* 8014 as a test organism. For evaluating coenzyme A, a weighed portion of the same liver used for studies on pantothenic acid content, was homogenized with ten volumes of ice-

Table 1

Group No.*	Supplement to 100 gm. basal ration	Pantothenic acid (γ/gm. liver fresh weight)	Coenzyme A (units/gm. liver fresh weight)
1	None	377 ± 27·6†	207 ± 12·7
2	2γ vitamin B_{12}	86 ± 8·1	81 ± 3·3
3	1,000γ orotic acid	234 ± 16·2	148 ± 8·8

* Five animals per group.
† Standard error of the mean.

cold water. The homogenate was boiled in a water bath, then cooled and centrifuged. In the aliquots of the supernatant, coenzyme A was determined by the usual procedure of Kaplan and Lipmann[6].

The results for liver pantothenic acid and coenzyme A are presented in Table 1. A striking increase in content of pantothenic acid and of coenzyme A concentration in the liver of rats kept on the vitamin B_{12}-deficient diet (group 1) for 8 weeks, is evident. These values appear much lower in rats of group 2 fed vitamin B_{12}. These results confirm the results previously reported in the chick and in the rat[2,3]. Orotic acid fed to vitamin B_{12}-deficient rats (group 3) exerts a vitamin B_{12}-like action in lowering the content of pantothenic acid and coenzyme A in the liver of male rats. Nevertheless, the effects of orotic acid are less, under our experimental conditions, than those shown by vitamin B_{12} itself. Therefore, orotic acid is not to be considered only as a factor in promoting growth and stimulating liver betaine–homocysteine transmethylase activity in rats deficient in vitamin B_{12} [1], since it also participates in the regulation of pantothenic acid and coenzyme A in the liver of male rats. These findings may point to a more extended metabolic relationship between vitamin B_{12} and orotic acid.

Enzymatic Formation of Aminomalonic Acid from Ketomalonic Acid

Recent work in this laboratory demonstrated the occurrence of a new enzyme, aminomalonic acid decarboxylase, in the posterior silk-gland of silkworm and in rat liver[1]. The fact that this enzyme was first observed in silkworm, which has a remarkably high activity of glycine synthesis[2], seems to suggest a physiological significance of the enzyme in the biosynthesis of glycine, although natural occurrence of this amino-acid has hitherto not been reported.

In the present communication, we report the formation of aminomalonic acid by an alanine-ketomalonate (mesoxalate) transaminase from silkworm and animal tissues. The first observation of this enzyme activity was reported by Braunstein in 1939 with pigeon-breast muscle; however, no attempt was made to identify the reaction product, aminomalonic acid, nor to characterize the enzyme further[3]. Later, Green *et al.* found that the purified glutamate–aspartate transaminase of pig heart showed a slight activity toward ketomalonate in place of oxalacetate[4].

The enzyme solution was prepared by homogenizing the posterior silk-glands of silkworms at the fifth instar stage with 3 vol. of 0·15 *M* potassium chloride solution (*p*H 7·8) and centrifuging off the undissolved material. The incubation mixture contained 1·0 ml. of the enzyme solution (approximately 1·0 mgm. N), 30 μmol. of disodium ketomalonate, 60 μmol. of DL-alanine, and 200 μmol. of borate buffer (*p*H 9·0) in a total volume of 3·0 ml. The mixture was incubated for 40 min. at 37° and deproteinized with sulphuric acid and sodium tungstate.

For the determination of the aminomalonate formed a simple method was devised: an aliquot taken from the supernatant solution was diluted with hydrochloric acid to give a final concentration of 0·1 *N* and heated for 30 min. in a boiling water-bath. This treatment proved to be sufficient for converting aminomalonic acid to glycine quantitatively. The glycine thus formed was determined by the method of Krueger[5]. Aminomalonic acid was also identified by paper chromatography and paper ionophoresis. The keto-acids were identified as their 2,4-dinitrophenylhydrazones by the method of Cavallini[6].

The activity of this enzyme solution (on the seventh day of the fifth instar stage), expressed as μmol. of the aminomalonate formed under the above condition, was about 9·2.

The *p*H optimum for the transamination of alanine–ketomalonate was found to be at 9·0–9·2. This is markedly different from those for the reactions of alanine–glutamate or alanine–aspartate, which have been reported to be 7·5 or 7·4, respectively[7]. This fact is interesting and may suggest that there might be a separate transaminase for this reaction from the alanine–glutamate or the alanine–aspartate enzymes. Transaminases with alkaline *p*H optima have been recently reported, namely, alanine–glyoxylate enzyme in silkworm (*p*H 9·0–9·5)[3], in *Pseudomonas* (*p*H 8·0–9·0)[8], and ornithine-α-ketoglutarate enzyme (*p*H 8·2–9·0)[9].

Of 17 different amino-acids studied in the presence of ketomalonate, alanine was the most active in forming aminomalonate. Glutamate, α-aminobutyrate, and aspartate also could act as amino-donors in decreasing order of reactivity. In the case of 13 other amino-acids there was no appreciable formation of aminomalonate from ketomalonate.

The activity of this enzyme preparation was 99 per cent inhibited by *p*-chloromercuribenzoate (10^{-3} *M*), 84 per cent by benzoquinone (10^{-3} *M*), 58 per cent by hydroxylamine (2×10^{-3} *M*), and 38 per cent by potassium cyanide (10^{-3} *M*).

Of all tissue homogenates tested for this enzymatic activity, the posterior silk-gland of silkworm showed the highest activity. Besides, it was observed that the activity of this tissue increased with time in the fifth instar stage. It may be noted that this tissue also exhibited the highest activity of aminomalonic acid decarboxylase; thus the distributions of these two enzymes in this tissue seem to be associated with each other. These facts may suggest a possible role of this transaminase in the biosynthesis of glycine, participating in the following metabolic pathways :

$$(\text{tartronate} \xrightarrow{10}) \text{ ketomalonate} \xrightarrow{\textit{transaminase}} \text{aminomalonate} \xrightarrow{\textit{decarboxylase}} \text{glycine}$$

The transaminase activity was also demonstrated in the homogenates of rat liver, rabbit liver and rabbit heart. The highest activity was observed with the rat-liver enzyme.

The enzyme was partially purified from the rat liver homogenate by fractionating with ammonium sulphate. The preparation was about 18 times as active as the starting material, but pyridoxal phosphate had no effect on the activity at this stage of purification.

Full details of this work will be reported in a future publication. Our thanks are due to Miss Aiko Kikuchi for her skilful technical assistance in this work.

Insulin - Cortisone Relationship in Experimental Teratogenesis

It is well known that the administration of large amounts of cortisone to experimental animals is associated with the production of hyperglycæmia[1]. There is also evidence from clinical cases that in diabetes the therapeutic use of cortisone increases considerably the daily amount of insulin required to maintain the blood-sugar within normal limits[2]. The nature of this contra-insulin effect of cortisone is uncertain, but it has been suggested that it may be due to excessive destruction of insulin since there is no definite evidence that contra-insulin factors are responsible for a marked increase in the peripheral requirements for insulin[3].

In a series of experiments reported recently we used the teratogenic effects of hypervitaminosis A as a base line for the study of the action of cortisone during pregnancy[4,5]. In these experiments one group of pregnant female rats of the Wistar strain received 60,000 I.U. vitamin A acetate daily by gastric intubation from the eighth to thirteenth days of pregnancy. Another group received the same treatment with, in addition, 20 mgm. of cortisone acetate daily by subcutaneous injection from the ninth to twelfth days. A third group received only the cortisone treatment. It was found that in the young obtained from these rats on the twentieth day of gestation there was an incidence of deformities of the brain and calvaria of 7·8 per cent when the rats had received vitamin A alone during pregnancy, and of 36·6 per cent when they had received both vitamin A and cortisone. There were no deformities in the young from those mothers which received cortisone alone (Table 1). These results were interpreted as suggesting that the cortisone potentiated the teratogenic effects of the hypervitaminosis A, and it appeared that this potentiating action might in some way be related to a disturbance of carbohydrate metabolism.

Table 1

Treatment	No. of dams	Total No. of young	No. of young with brain deformities	Percentage of young with brain deformities
Vitamin A	12	77	6	7·8
Vitamin A, cortisone	12	41	15	36·6
Cortisone	12	73	0	0

We decided therefore, in view of the known contra-insulin effects of cortisone, to carry out further experiments in order to examine the possibility that insulin might exert a contra-cortisone effect in relation to the production of malformations. In these experiments one group of pregnant female rats was given vitamin A for the same period and in the same doses as in the earlier experiments. In addition, they received 1·5 units of protamine zinc insulin by subcutaneous injection, daily from the ninth to twelfth days of pregnancy. Another group received both vitamin A and cortisone in the same quantities as previously administered, but were also given 1·5 units of protamine zinc insulin daily by subcutaneous injection from the ninth to twelfth days. The results of these experiments are shown in Table 2. It will be seen that the incidence of deformities in the young fell from 36·6 to 1·2 per cent when insulin was given in addition to vitamin A and cortisone; and that while there was an incidence of 7·8 per cent in the young of dams which received vitamin A alone, no young with brain deformities were obtained from the dams which received insulin in addition to vitamin A.

Table 2

Treatment	No. of dams	Total No. of young	No. of young with brain deformities	Percentag young with brain deformities
Vitamin A, insulin	12	47	0	0
Vitamin A, cortisone, insulin	12	79	1	1·2

These findings indicate that the potentiating action of cortisone in relation to the production of malformations by hypervitaminosis A is wholly prevented by the administration of insulin. Further, it appears possible that insulin may have some effect in protecting the young against the teratogenic effects of hypervitaminosis A.

We acknowledge with gratitude the assistance of a grant from the Nuffield Foundation.

Reversibility of the Inactivation of Rous Sarcoma Extracts by Detergents

The infectivity of an aqueous extract from a Rous sarcoma is lost if cetyl trimethyl ammonium bromide ('Cetavlon'), a cationic detergent, is added to the active extract[1]. By further addition of an acid colloid substance, like ribonucleic acid[2] or heparin, to the non-infective system infectivity is restored.

From the results obtained by Pirie and co-workers[3-6] on some plant viruses, including the tobacco mosaic virus, treated with anionic detergents, and by Pfankuch and Kausche[7] on tobacco mosaic virus with cationic detergents, the mechanisms of the actions of the two types of detergents on tobacco mosaic virus appear to be different. We have explored the possibility of an analogous behaviour of Rous sarcoma extract towards the two types of detergent, with particular reference to the reversibility of inactivation. The results are given in Tables 1 and 2.

The extract was prepared with a Miller and Golder's buffer[8] 0·14 *M*, *p*H 7·0. The initial concentration of extract was 5 per cent. After centrifuging at 1,500 *g* for 60 min., hyaluronidase, 5 U.V./ml. (Ialovis Vister) was added as solubilizer, and after 30 min. the extract was centrifuged at 15,000 *g*. All operations were carried out at 3° C.

In the experiments with 'Cetavlon' the proportion detergent/infective extract, was 2 mgm./ml., and the amount of acid colloid (heparin) needed to restore infectivity was equal by weight to the amount of 'Cetavlon'. In the experiments with the anionic detergent (sodium lauryl sulphate), the proportions were 0·4 mgm./ml., and the amount of basic colloid (protamine) added was equal to the weight of anionic detergent. Inoculations (standard amount, 2 ml.) were made in the breast muscles of 8-week-old chickens, all from the same breed. They were killed between the thirteenth and fifteenth day of the experiment, at which time the first control animals were beginning to die.

It appears from the results obtained that, whereas the cationic detergent has a reversible action, as is shown by the restoration of infectivity in the inactivated system (extract + 'Cetavlon'), such a reversibility does not occur with the anionic detergent, even after addition of a basic colloid, like protamine.

Effect of Creatine Phosphate Administration on the Cardiac Adenosine Triphosphate of Thyroxinized Rats

The amounts of adenosine triphosphate, creatine phosphate and inorganic phosphorus in the heart of hyperthyroid animals are below normal. These amounts are restored to about the normal level by administration of adenosine triphosphate, whereas with cocarboxylase and organic phosphates restoration is incomplete[1]. Moreover, thyroxin intoxication reduces the creatine content of the skeletal muscle and the rate of creatine synthesis by liver[2].

We have sought to establish if creatine phosphate, which is essential in oxidative phosphorylation, affects the reduction of this process in the heart, induced *in vivo* by thyroxin in doses of 0·01 mgm. per animal.

0·01 mgm. D,L-thyroxin was daily injected intramuscularly into each of twenty-four rats, which were then divided into four lots. Lot *B* received no further treatment; lot *C* daily received 0·1 mgm. of buffered creatine phosphate per animal injected intramuscularly; lot *D* received daily 5 mgm. of buffered creatine per animal, injected intramuscularly; the rats in lot *E* each received a single injection of both creatine phosphate and creatine at the same doses as above. A fifth lot (*A*) of normal animals was used as control. After fifteen days the animals

D (6)	121 ± 16	< 10	325 ± 29	367 ± 38	151 ± 17
E (6)	230 ± 28	165 ± 21	418 ± 46	376 ± 41	164 ± 14

Values ± standard error

were killed by bleeding and determinations of adenosine triphosphate, creatine phosphate, inorganic phosphorus[3], creatine[4] and glycogen[5] were carried out.

As shown in Table 1, administration of creatine phosphate partially prevents the fall of adenosine triphosphate and creatine phosphate content of the heart in animals given thyroxin at high dosage. Creatine alone cannot do this, and not only the adenosine triphosphate content but also creatine phosphate content remain low.

Phospholipids, Proteins and Platelet-Lipoid

The time taken for Russell viper venom to accelerate the clotting of fasting human plasma poor in platelets—the Stypven time—is relatively long. The addition of very small quantities of some active phospholipids[1,2] to this system produces a shortening of the Stypven time, and the shortening is proportional to the quantity added. It may be concluded that there is very little available active phospholipid in fasting platelet-poor plasma. A simple phospholipid extraction of fasting platelet-poor plasma yields a material that greatly accelerates the Stypven time of platelet-poor plasma. It is concluded that there are molecules of active phospholipids in plasma, but that they are 'unavailable' for this test and presumably are bound in the plasma proteins.

If a critical strength of an isolated phospholipid, active in the Stypven system, is added to platelet-poor plasma at 37° C. or 10° C. it is found that this activity has decreased at the end of 2 hr. (To 0·5 ml. of fasting platelet-poor plasma is added 0·5 ml. of a predetermined concentration of an active phospholipid in distilled water. 0·1 ml. of this mixture is transferred to another 0·1 ml. sample of stock plasma and the Stypven time determined. This should be about 14 sec. if the plasma alone has a Stypven time of 20 sec. At the end of 2 hr. a further 0·1 ml. of the mixture is transferred to 0·1 ml. of stock plasma and the Stypven time recorded. Another 0·5 ml. of plasma and 0·5 ml. of phospholipid are then mixed and 0·1 ml. transferred to 0·1 ml. of stock plasma and clotted as before to check that the plasma, Stypven and original phospholipid activity have not altered.) It may be concluded that less phospholipid is available after 2 hr. Plasma rich in heparin-clearing factor gives the same results as normal plasma. It is unlikely that any enzyme system has altered the chemical composition of the phospholipid since this reaction proceeds equally well at 10° C. as at 37° C. A possible explanation is that the phospholipid has become associated with the plasma proteins and is no longer 'available' for this test.

Intact platelets are inactive in accelerating the Stypven clotting time of plasma. If they are mechanically fragmented, a potent accelerator becomes available. The properties of fragmented platelets in all coagulation tests (except clot retraction) are identical with various cephalins including phosphatidyl-ethanolamine, phosphatidyl serine and phosphatidyl inositide[3] and it has been suggested that the activity of platelet-lipoid is due to its content of any one or a mixture of these or similar 'active' phospholipids.

If platelet fragments are incubated in a critical strength with platelet-poor plasma the acceleration of the Stypven time caused by their addition does not decrease in two hours. A protein-free phospholipid extract of platelets behaves like an active phospholipid extracted from any other source.

If the two previous conclusions are correct, this last observation may suggest that if platelet-lipoid is active in blood coagulation by virtue of a phospholipid prosthetic group, then there is another part of the molecule which prevents the whole molecule from becoming associated with the plasma protein and thereby losing its activity. In a natural state, platelet-lipoid is almost certainly associated with protein. The activity of platelets may, therefore, depend on a preferred orientation in the platelet-protein molecule of a prosthetic phospholipid group which is 'available', while the phospholipids in plasma proteins are differently orientated and inactive or 'unavailable'.

Further work is in progress to expand and confirm these tentative conclusions.

Adrenocorticotrophic Hormone in the Blood of Adrenalectomized Rats

It is well known that stress results in increased activity of the adrenal cortex which is caused by an increased secretion of adrenocorticotrophin by the pituitary gland. However, the exact mechanism which controls the secretion of this hormone is not fully understood. Sayers and Sayers[1] suggested that stress causes an increased utilization of adrenocortical steroids by the peripheral tissues and the resulting low blood level of corticoids acts as a stimulus to the pituitary gland to increase its secretion of adrenocorticotrophin. The Sayers hypothesis received convincing support from the results of the investigations of Taylor, Albert and Sprague[2], Gemzell, Van Dyke, Tobias and Evans[3] and Sydnor and Sayers[4], who found that animals with adrenocortical insufficiency exhibited a high blood level of adrenocorticotrophin. On the other hand, Barrett and Hodges[5] were unable to demonstrate any difference in plasma concentrations of adrenocorticotrophin between normal and adrenalectomized rats three, six and twelve days after the removal of the adrenal glands. The explanation of the discrepancy between these results was difficult to find. However, Barrett and Hodges[5] did not use the conventional technique of Sayers, Sayers and Woodbury[6] which employs hypophysectomized rats for the bioassay of adrenocorticotrophin, but a modification of the method described by Hodges[7] in which normal rats pretreated with deoxycorticosterone acetate were used. The possibility exists that the method was not sensitive enough to detect differences between the plasma-levels of adrenocorticotrophin in the normal and adrenalectomized animals or may even have been completely unsatisfactory for the assay of the hormone in blood. Therefore, it seemed essential to repeat and extend the work using hypophysectomized rats for determination of the adrenocorticotrophin.

Blood was collected from normal albino female Wistar rats and from similar adrenalectomized animals at various time-intervals after the removal of their adrenal glands. Plasma was separated and assayed for content of adrenocorticotrophin by the adrenal ascorbic acid depletion method described by Sayers *et al.*[6]. It was found that normal rats exhibited no detectable circulating level of the hormone, neither did animals five days after adrenalectomy. Adrenocorticotrophin was just detectable in the plasma of rats which had been adrenalectomized ten days previously, but its concentration was considerably less than 5 μgm./100ml. plasma. Twenty-three days after adrenalectomy the concentration of the hormone in the plasma had risen to 10·6 μgm./100 ml. (with limits of error ($P = 0 \cdot 05$) 7·4–15·2 μgm./100 ml.), and the same high circulating level was still present in rats adrenalectomized thirty-four days previously. From the results of this experiment it appears that no rapid and well-maintained increase in the concentration of adrenocorticotrophin in plasma follows adrenalectomy in the rat until three to five weeks after the operation, when there exists a remarkably high circulating concentration of the hormone.

There are no serious discrepancies between these results and those previously reported by Barrett and Hodges[5]. The findings also agree with those of Brodish and Long[8], who demonstrated by a cross-circulation technique that the adrenalectomized rat did not maintain a high circulating level of adrenocorticotrophin until two weeks or more after the removal of the adrenal glands. Furthermore, Barrett and Sayers (Barrett, personal communication) have recently demonstrated similar time-relations in the changes in the concentration of adrenocorticotrophin in the blood of adrenalectomized rats. These results do not contradict the evidence that the release of the hormone from the adenohypophysis may be controlled by the level of adrenal cortical hormones in the blood. However, it appears that in the rat there is an interval of at least two weeks before the pituitary gland adapts itself to secrete *and maintain* an enormously increased output of adrenocorticotrophin in response to the complete absence of circulating corticoids.

This investigation was supported by grants from the Medical Research Council and the Wellcome Trust. Our thanks are due to Miss Dorothy Bathgate and Miss Joan Vernikos for technical assistance.

Isomeric Chondroitin Sulphates

A RECENT communication[1] claims to "confirm Meyer's hypothesis that chondroitin sulphates *A* and *C* are only two fractions of the same polydisperse substance". Apparent lack of agreement in nomenclature[2–4] further emphasizes the need for clear differentiation of the isomeric chondroitin sulphates of connective tissue. These three substances, chondroitin sulphate *A*, chondroitin sulphate *B* and chondroitin sulphate *C*, respectively, in the nomenclature of Meyer *et al.*[2], have been found to be linear polyelectrolytes with similar chain configuration-charge relationships. Chondroitin sulphates *A* and *C* have been clearly distinguished as molecular individuals by comparison of molecular constants and physical properties.

Chondroitin sulphate *B* may be readily differentiated from *A* and *C* by enzymatic and chemical techniques[2]. The *A* and *C* sulphates, however, differ only slightly in optical rotation and in solubility, a property also dependent upon molecular weight. These two, however, may be easily differentiated by their infra-red spectra (Fig. 1) in the 700–1,000 cm.$^{-1}$ region where chondroitin sulphate *C* has unique bands at 1,000 cm.$^{-1}$, 820 cm.$^{-1}$ and 775 cm.$^{-1}$. Chondroitin sulphate *A* has bands at 928 cm.$^{-1}$, 852 cm.$^{-1}$ and 725 cm.$^{-1}$; *B* resembles *A*, with bands at 928 cm.$^{-1}$, 855 cm.$^{-1}$, 840 cm.$^{-1}$ and 712 cm.$^{-1}$.

Spectral measurements on fractionated preparations confirm a suggestion[2] that chrondroitin sulphate *C* is present in human umbilical cord. On the basis of published spectra (and optical rotations), the mucopolysaccharide from nuclei pulposi called "chondroitin sulphuric acid-*B*"[3], and the chondroitin sulphate from shark cartilage[7], may also be regarded as the *C* sulphate. In disagreement with a previous report[2], preparations from rabbit skin[8] have been found to consist of a mixture of *A* and *B* sulphates. Small amounts of the *A* sulphate have been detected in samples of β-heparin.

On the basis of previous assignments of bands[3], it appears that the sulphate group has an axial configuration in chondroitin sulphate *A* and *B* and an equatorial configuration in sulphate *C*. In agreement with recent reports[9] a possible interpretation places the sulphate group on the C-4 position in the hexos-

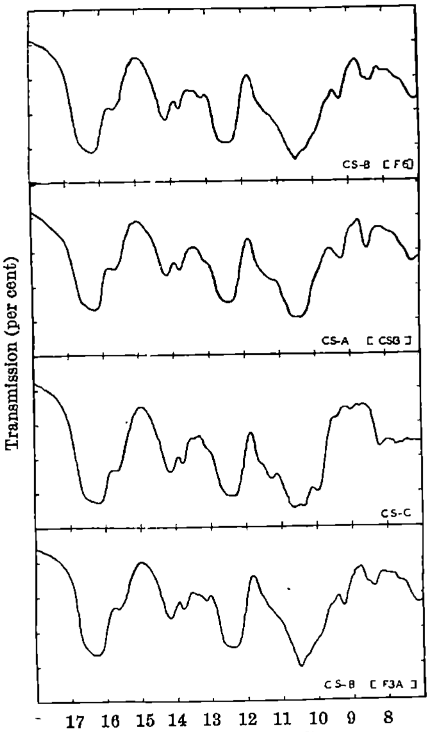

Fig. 1. Infra-red spectra for isomeric chondroitin sulphates obtained on a Perkin-Elmer spectrophotometer, model 21. with sodium chloride prism. 1·0 mgm. of the sodium salt of each polysaccharide was mixed with 150 mgm. potassium bromide, formed into a film of 0·45 mm. thickness (nominal) and compared with a potassium bromide blank. *A* was prepared from bovine nasal cartilage (ref. 5). Chondroitin sulphate *B* preparations were obtained by fractionation of a sample of β-heparin from bovine lung (ref. 6). One of these fractions, *F*-6, contained 20 per cent of the *A* sulphate. The *C* sulphate was a preparation from a human chordoma (ref. 2)

amine moiety of both the *A* and *B* sulphate, and on the C-6 position of the hexosamine moiety of the *C* sulphate.

This work, a fuller account of which is in preparation, was supported by a grant from the Chicago Heart Association and carried out during the tenure of an established investigatorship of the American Heart Association. I am indebted to Mr. Robert Hart for the spectral measurements, to Dr. A. Winterstein for the preparation of β-heparin, and to Dr. K. Meyer for the chondroitin sulphate *C* preparation.

Effect of Hypophysectomy on the Ability of Rat Liver Microsomes in a Cell-free System to incorporate Radioactive Amino-Acids into their Proteins

THE incorporation of DL-leucine labelled with carbon-14 into the proteins of a cell-free system[1] prepared from rat liver has been compared with the incorporation obtained under the same conditions with a system prepared in exactly the same way from the livers of hypophysectomized rats. The system was prepared by homogenizing liver in a buffered-sucrose medium[1] and spinning at 14,000*g*. The unsedimented portion was incubated with the sodium salt of adenosine triphosphate, the sodium salt of creatine phosphate and DL-leucine-1-^{14}C. The incorporation obtained varied with the experimental conditions used, but in all cases less amino-acid was incorporated into the protein of hypophysectomized rats. The specific activity of the protein from hypophysectomized rats in ten experiments was between 20 and 70 per cent of that found in the normal control system. Treatment of the hypophysectomized rats with growth hormone restored almost to the normal level the ability of the cell-free system to incorporate amino-acids. This *in vitro* result is compatible with the *in vivo* observations that hypophysectomy results in a fall in liver weight and protein content and that treatment with growth hormone prevents this fall[2].

Incorporation into the proteins of the cell-free system takes place in at least two distinct steps. Hoagland, Zamecnik and Keller[3] have shown that the first step is the activation of the amino-acid by adenosine triphosphate and an enzyme present in the soluble fraction of the cell. Later the carboxyl-activated amino-acid is incorporated into protein on the ribonucleoprotein particles of the microsomes[4,5]. There may be intermediate steps between these two processes, and Hoagland, Zamecnik and Stevenson[6] have some evidence which implicates part of the ribonucleic acid of the soluble fraction of the cell in such a role.

The microsomes were separated from the activating enzymes and ribonucleic acid in the soluble fraction of the cell by centrifugation of the cell-free system at 105,000*g*. Neither the microsomes nor the soluble fraction when incubated separately in the presence of adenosine triphosphate, creatine phosphate and DL-leucine labelled with carbon-14 showed much incorporation, but incorporation into microsomal protein, to the extent found in the unseparated system, occurred when these two fractions were incubated together. A similar experiment (Table 1) with microsomes and soluble fraction from hypophysectomized rats showed the expected smaller incorporation into these microsomes. The microsomes from hypophysectomized rats were now incubated with the soluble fraction (supplemented with adenosine triphosphate and creatine phosphate) prepared from the normal animals and almost the same, smaller, incorporation was found. When normal microsomes were incubated with soluble fraction from hypophysectomized rats, almost normal amounts of radioactive amino-acid were incorporated into the microsomes. This shows that hypophysectomy was not causing changes in the activating enzymes, the energy generating system, or the possible ribonucleic acid intermediate[6] to any great extent, for the soluble fraction from hypophysectomized rats is capable of

Table 1. INCORPORATION OF DL-LEUCINE LABELLED WITH CARBON-14 INTO MICROSOMAL PROTEIN OF A CELL-FREE SYSTEM

	c.p.m./mgm. of microsomal protein
Normal microsomes + normal soluble fraction	146
Hypophysectomized microsomes + hypophysectomized soluble fraction	76
Hypophysectomized microsomes + normal soluble fraction	87
Normal microsomes + hypophysectomized soluble fraction	138

4 mgm. of microsome protein and 6 mgm. of soluble fraction protein were incubated at 37° in a buffered-sucrose medium (ref. 1) at *p*H 7·5 with adenosine triphosphate (6×10^{-3} *M*), creatine phosphate ($2 \cdot 3 \times 10^{-2}$ *M*) and DL-leucine-1-^{14}C ($1 \cdot 3 \times 10^{-4}$ *M* and about 40 μc./mgm.).

causing almost as great an incorporation as the soluble fraction from normal rats if it is incubated with normal microsomes. Most of the fall in incorporation resulting from hypophysectomy must be caused by some deficiency of the microsomes themselves. It is well known[7,8] that hypophysectomy in the rat is followed by a fall in the cytoplasmic ribonucleic acid content of the liver which can be prevented by administration of growth hormone. The observed changes in incorporating ability do not, however, depend on the total ribonucleic acid content of rat liver. Clark, Naismith and Munro[9] have shown that a large fall in the ribonucleic acid of rat liver occurs when rats are fasted, yet I have found incorporation of amino-acid into microsomes of cell-free systems from both normal and hypophysectomized rats fasted for 18 hr. to be the same as in fed animals. The ribonucleic acid which is broken down as a result of 18 hr. of fasting is not the same ribonucleic acid which is responsible for amino-acid incorporation into protein, nor is it the same as the ribonucleic acid which is lost as a result of hypophysectomy.

These experiments do not exclude the possibility that hypophysectomy also influences protein synthesis by inhibiting the entry of amino-acids into the cell or by decreasing the amount of energy available for these processes or by some other mechanism. It is, however, clear that hypophysectomy markedly reduces the ability of rat-liver microsomes to incorporate activated amino-acids into protein. The depression of protein synthesis after hypophysectomy[2] is probably secondary to this effect on the microsomes.

It is hoped to publish full details of these experiments in due course. I wish to express my thanks to Prof. F. G. Young for his interest and encouragement, to the Council of the Royal Society for a grant-in-aid, to Miss M. B. Thomas who performed the hypophysectomies and to Mr. D. C. Gardiner for highly skilled assistance.

Adrenaline and Noradrenaline Content of the Adrenal Gland of the Rat following Depletion with Reserpine

It has been shown that reserpine causes a loss of catechol amines from cat[1] and rabbit[2] adrenal glands. In the experiments reported here a study has been made of the adrenaline and noradrenaline content of rat adrenal glands over a period of a month, reserpine being administered for the first 3 days. Thus information concerning the loss and replacement of amines was obtained.

Albino rats weighing 150–190 gm. were used, and in any one experiment all were of the same sex. In all instances groups of 5 rats were used, and every group had its own control, also of 5 rats. Each test animal was given reserpine (1 mgm./kgm.) subcutaneously, daily for three consecutive days. The control rats were given the reserpine solvent only. Groups of rats, with their respective controls, were killed at 3, 7, 14, 21 and 28 days following the first injection. In all, 170 rats were used. The adrenaline and noradrenaline contents of extracts of the glands were determined biologically, using the blood pressure of the hexamethonium-treated cat and the isolated uterus of the rat in dicestrus as test preparations. The results were calculated by the formula of Bülbring[3] and expressed in μgm./gland.

It was found that, at 3 days, reserpine caused a similar percentage loss of adrenaline and noradrenaline. This was despite the fact that normal rat adrenal glands contain only 10 per cent of noradrenaline. In all experiments the degree of depletion of both amines was of the order of 50 per cent. Following the depletion, the adrenaline content of the glands slowly returned to its initial, non-depleted value by 21 days and afterwards stayed at this level. In contrast, noradrenaline increased to several times its original value by seven days and then decreased to regain its original value by 21 days. Fig. 1 shows the typical percentage depletion of amines and their subsequent replacement. It may be noted that at the peak of the noradrenaline increase, the glands contained approximately 30 per cent of noradrenaline. All experiments gave similar results, there being no difference in this respect between male and female rats.

These results are further evidence that noradrenaline is a precursor of adrenaline in the rat, because otherwise it would be expected that the two amines

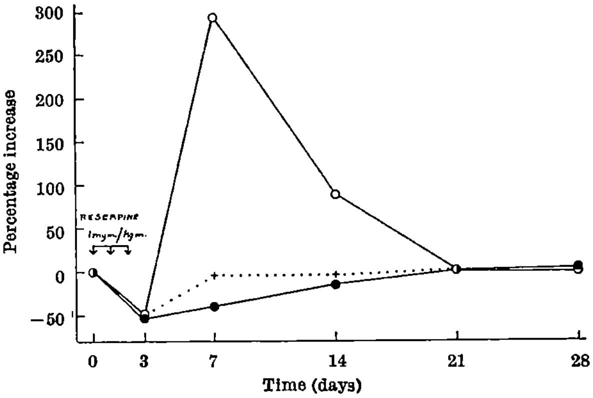

Fig. 1. A composite diagram to show the rate of replacement of adrenaline (●), of noradrenaline (○) and of total amine (+) in the adrenal gland of the rat, at various time intervals following depletion with reserpine. All results are expressed as percentages of the amine contents of the respective control glands

would return to their normal levels in a similar manner. The transient increase in the noradrenaline content, above the normal value, indicates that the rate of methylation of noradrenaline to adrenaline is slower than the rate of formation of noradrenaline. It is of interest that Butterworth and Mann[4] have obtained a similar depletion and replacement of catechol amines in cat adrenal glands, depleted with acetylcholine. Work is now in progress to determine whether this action of reserpine is central or peripheral.

We wish to thank Mr. C. S. Message, of Ciba Laboratories, Ltd., for generous gifts of reserpine.

Nuclear Transplantation in *Xenopus laevis*

Briggs and King[1] have devised a technique with which they were able to transplant nuclei from cells of early embryos into unfertilized eggs of *Rana pipiens* from which the female pronucleus had been removed. In this way they could test the extent to which a nucleus from embryos up to neurula stages could produce normal development when transplanted into an enucleated egg[2].

We have modified this technique to start similar experiments on *Xenopus laevis*. We have not so far removed the female pronucleus because it does not usually participate in development. This useful fact was discovered through the use of a nuclear marker, visible in interphase nuclei (Fischberg, M., Smith, S., and Elsdale, T., unpublished).

A survey of the number of chromosome sets present in 70 normal and abnormal tadpoles gave the results shown in Table 1. The tetraploid embryos are usually due to the doubling of the diploid chromosome number of the injected nucleus, and not to the participation in development of the female pronucleus[1].

Table 1

	No.	Per cent
Diploids	55	79
Tetraploids	12	17
Mosaics, etc.	3	4
Total analysed	70	100

Table 2 consists of the combined results from six of our more successful experiments, and shows the number of embryos that appear normal at various stages of development up to the feeding tadpole. The donor nuclei came from embryos between late blastula and late gastrula stages, and between these limits the proportions of normal host embryos and the types of host abnormalities at different stages are similar; these appear not to be dependent upon the developmental stage of the donor nucleus and the germ layer from which it derives. Table 2 is heterogeneous, because it consists of the results from twelve different categories of donor nuclei (four temporal stages and three germ layers); we find that the numbers in the individual categories are too small to relate the abnormalities of transplanted embryos to the origin of the donor nucleus.

Table 2

	No.	Per cent
Total transfers	905	100
Uncleaved	387	43
Cleaved normal and abnormal	518	57
Normal gastrulæ	193	21
Normal at hatching	89	10
Normal feeding tadpoles	61	7

We have obtained normal tadpoles from eggs injected with ectoderm and endoderm nuclei from late gastrulæ. King and Briggs[2] obtained 10–12 mm. tadpoles from nuclei of ectoderm, chorda-mesoderm, and endoderm from late gastrulæ of *Rana pipiens*; but the majority of transplants from chorda-mesoderm and endoderm gave embryos developing syndromes of abnormalities specific for the origin of the donor nucleus.

We are continuing the work along two main lines: (*a*) to find the latest stages that provide donor nuclei which give normal development when transplanted into unfertilized eggs; (*b*) to see if embryos develop syndromes of abnormalities specific for the origin of the donor nucleus.

This work has been made possible by contributions from the British Empire Cancer Campaign (M. F. and T. E.) and the Medical Research Council (J. B. G.).

Effects of Heat and Loss of Moisture on the Dormancy of Barley

In a paper on the effects of desiccation on delayed germination in barley it is suggested that ripening and germination are directly related to the moisture-content of the grain[1]. The observation is made that complete germination occurred when the moisture content naturally fell to 12·7 per cent or when artificial drying was used.

'Desiccation' was the word employed to describe drying at 40° C. It is the purpose of the present communication to direct attention to the fact that temperature can have an effect independent of the loss of moisture of harvested samples showing dormancy under seed testing conditions[2].

In an attempt to speed germination, treatments were given which included heat-sealing in polythene bags, some of which contained self-indicating silica gel, and oven-drying at 39° C. Room temperature, in late summer, varied between 16–24° C. Moisture-content was determined with a Marconi 933*A* meter, and checks made with a Carter/Simon oven. From each treatment 300 seeds were placed on damp sand.

Samples of Pioneer barley *A*27 (moisture content 16·3 per cent and germination 95 per cent), known to be dormant were sealed in polythene with silica gel. Overnight the moisture-content fell to 12·5 per cent when kept at 4° C. and to 10·7 per cent at room temperature. Germination after 6 days reached only 60 per cent and 57 per cent respectively; not significantly different from the control at 51 per cent.

At the same time samples of *A*27 were placed at 39° C. for 4 days. Germination after 6 days reached 95 per cent whether the sample was sealed (with a moisture loss of $\not>$ 1 per cent) or had dried down to 8·4 per cent moisture. The control, kept in a closed but not sealed polythene bag at room temperature for the 4 days, grew 75 per cent in 7 days.

Similar treatment was given to barley *A*29, moisture content 17·5 per cent, germination without treatment 60 per cent. After 2 days (or 4 days) at 39° C. germination reached 95 per cent or more with moisture-losses of either $\not>$ 1 or 7·5 per cent. Germination was adversely affected when grains on damp sand were sealed in polythene at 39° C. for 2 days.

It is suggested that, during natural desiccation, temperature, and probably time, may be more important factors than the precise moisture-content in affecting this type of delayed germination.

A Mechanism of Resistance to Parathion in *Musca domestica* (L.)

THE ease with which the chlorinated hydrocarbons give rise to the development of resistance in *Musca* has led to the use of organo-phosphorus insecticides for controlling flies. However, development of resistance to some of these compounds appears possible also, although at present it seems to be less serious than in the case of the chlorinated compounds. An investigation into the mechanisms causing resistance to these substances has been undertaken.

Three strains, namely *S*, U_2 and *D*, with different parathion resistances were used in the present investigation. *S* is our susceptible laboratory strain which is also susceptible to parathion. Strain U_2, being highly resistant to γ-BHC and related compounds, shows some resistance to parathion, although it has never been in contact with organo-phosphorus insecticides. Strain *D* was collected by Keiding[1] on a farm (*J*79) in Denmark, where parathion had been used for a period of three years. It was submitted to further selection with parathion in the laboratory. Dr. Keiding kindly put this strain at our disposal.

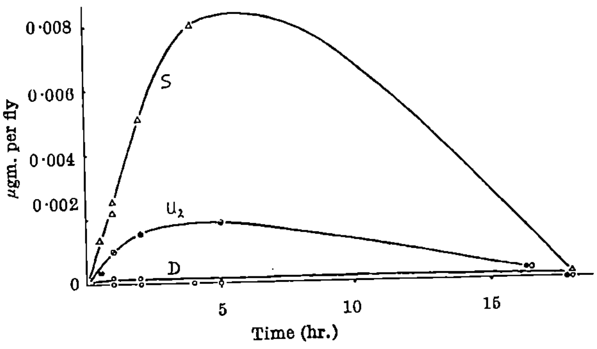

Fig. 2. Amount of paraoxon found in flies after injection of 0·01 µgm. of parathion in strains *S*, U_2 and *D*

It is assumed that parathion is oxidized in the flies to paraoxon, just as is the case in mammals[2] and in the roach (*Periplaneta americana*)[3], and that this compound exerts its action by inhibition of an enzyme, probably cholinesterase. As a first step, the susceptibilities of the strains to parathion and paraoxon were compared, using a contact method and injections (Fig. 1). In the contact experiments the flies were exposed in jars for twenty-four hours to a residue in a thin film of peanut oil. For the injections an emulsion of parathion dissolved in peanut oil was used, whereas paraoxon was injected as a solution in insect saline.

It was found that there is still a marked difference between the strains after injection of parathion. Therefore decreased penetration cannot be the cause of the resistance, or at least not the only cause. The differences found in the contact toxicity of paraoxon indicate that a resistance mechanism must be present that affects the susceptibility to parathion only through an influence on the toxic action of paraoxon. The difference after injection of paraoxon is discussed below.

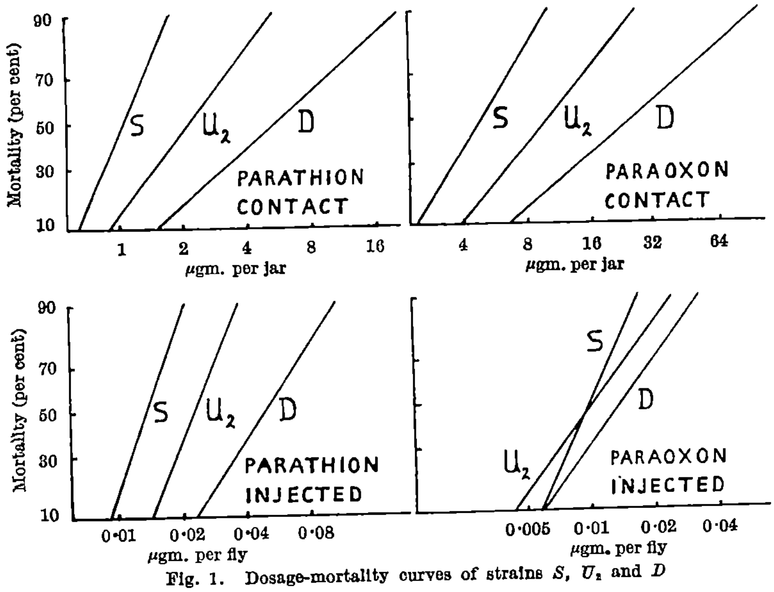

Fig. 1. Dosage-mortality curves of strains *S*, U_2 and *D*

The amount of paraoxon present after injection of parathion was estimated in the three strains. Upon injection the flies were kept at 25° C. for varying periods of time, after which they were homogenized and incubated for some time to bring the paraoxon in contact with the cholinesterase. The cholinesterase activity was estimated by the method of Hestrin[4]. The amount of paraoxon was determined by comparing the inhibition found with that caused by known quantities. Fig. 2 shows the results of injecting 0·01 µgm. of parathion per fly. A very large difference between the amounts of paraoxon in the three strains is apparent. The same was found after injections with larger doses. Injection of 0·02 μgm. resulted after a period of 5 hr. in about 0·017, 0·005 and 0·003 μgm. in strains *S*, U_2 and *D* respectively.

In another series of experiments 0·01 μgm. of paraoxon per fly was injected. After different periods of time a number of flies were homogenized, incubated and the inhibition of the cholinesterase was determined. Paraoxon was found to be eliminated more rapidly by the more resistant flies. Elimination of about 0·0085 μgm. of paraoxon was found after 6¾, 4 and 2¾ hr. in the strains *S*, U_2 and *D* respectively.

The fact that only small differences in susceptibility of the strains were found after injection of paraoxon may be explained by the very rapid action in this case. Apparently the elimination process can only protect the flies from the action of paraoxon if it appears in the body gradually.

The occurrence of only small differences in susceptibility after injection of paraoxon makes it less probable that an alteration of the affected enzyme is a cause of the resistance. As cholinesterase may possibly be this enzyme we estimated its activity in the strains and the amount of paraoxon required for its inhibition *in vitro*. Neither quantitative nor qualitative differences were found which could contribute to the resistance.

It is remarkable that strain U_2 —which was selected with γ-BHC —eliminates paraoxon much faster than strain *S*. This difference is not incidental, for it was found that strain *U*, a substrain of U_2 that has been bred for some years without selection and has lost its resistance to γ-BHC, has the same susceptibility to parathion as strain *S* and about the same capacity to eliminate paraoxon. There seems to be in this case some relation between the resistances to these quite different types of insecticides.

Boron Deficiency in Tea

TEA must be the last commodity crop to show a need for boron. This is probably due to its low calcium requirement and to the fact that tea gardens are very rarely limed. The boron deficiency syndrome first appeared accidentally in a pot experiment testing five different soils for natural potassium uptake. All plants in two soils when they were about 30 cm. high died off at their growing points and developed corky excrescences on the undersides of petioles. These two soils were known from previous pot tests with tomatoes to be deficient in boron.

Half the plants in the experiment were then treated with a complete nutrient solution and half with the same solution without boron. Growth response to each treatment was rapid; but when the new shoots of the plants receiving no boron were about 25 cm. long, brown spots appeared, first in the petioles and then in the laminæ of the flush. As the young leaves developed, the brown spots enlarged in the laminæ and spread along most of the petioles and mid-ribs with considerable suberization. Normal growth was severely upset and affected leaves were strongly wrinkled and contorted. Cork was particularly thick on the underside of the petioles and often spread to the adjacent stems. Laminæ of affected petioles drooped to a near vertical position but remained quite turgid. Internodes were reduced to less than 1 cm. and finally growing-points died. Old leaves that had reached maturity before the boron deficiency became acute, exhibited suberized cracks on both sides of the upper surface of the main veins.

So far as can be ascertained the above has not yet been observed in field-grown tea bushes.

Rate of Calcium Loss resulting from Ammonium Sulphate Treatment of a Tea Soil

FULL results of our investigation into the effect of treatment with ammonium sulphate on the calcium economy of a tea soil will be published elsewhere[1]; but certain preliminary observations can now be made. The soil under study, which is typical of the tea soils of north-east India, can be described as a highly acid loamy sand of alluvial origin, having *p*H about 4·5 and a low calcium content.

It is generally assumed[2] that the loss of bases resulting from application of 100 lb. of ammonium sulphate can be made good by applying about 110 lb. of calcium carbonate to the soil. The calculated rate of loss under our field conditions is, however, only about a third of the above figure. Our results appear to provide an indirect proof that tea growing in an acid soil and manured with ammonium sulphate absorbs nitrogen in the 'ammonia' form. It also follows from the results that, under our conditions, the tea plant takes up a considerable portion of its nitrogen requirement as 'free nitric acid'. The theoretical basis on which this latter deduction is made has already been explained by Pierre[3]. A chemical analysis of the tea plant growing in an acid soil supports the above deductions. As an illustration, the acidic and basic constituents in plucked tea shoots are given below (calculated by Truog's method[4]). The figures quoted do not refer to the whole plant and will not hold good in all cases, but they will serve to indicate the nature of the balance.

Total base-forming constituents, approximately 90 m.equiv./100 gm. dry weight.
Total acid-forming constituents excepting nitrogen, approximately 38 m.equiv./100 gm. dry weight.
Nitrogen content, approximately 375 m.equiv./100 gm. dry weight.

Our results also indicate that the rate of loss of calcium is higher in the case of shaded tea (that is, tea growing under a canopy of shade trees, in this instance, under *Albizzia chinensis* (Osbeck) Merr.) as compared with unshaded tea. Andrews and Cowart[5] have calculated the effects of fertilizers on the base supply of cotton soils from the unrecovered nitrogen percentage and chemical analysis of seed cotton. Although our case is complex, the same method can be used in the case of tea also. Under the plains conditions in north-east India, 1 lb. of nitrogen applied in the form of ammonium sulphate to unshaded tea is known to bring about an ultimate increase in yield of about 8 lb. of made tea. The corresponding increase in the case of shaded tea, on the other hand, is only about half that amount. From the nitrogen content of plucked shoots, an idea can be obtained about the percentage nitrogen unrecovered, although not all of it may necessarily be lost by leaching. It would appear that a higher percentage of nitrogen remains unrecovered in the case of shaded tea, and this, it is suggested, may serve as a qualitative explanation for the higher rate of calcium loss noted in the case of shaded tea.

Occurrence of Sex Chromatin in the Basal Cells of the Epidermis and in Basal Cell Carcinomata

THE characteristic mass of sex chromatin, first observed by Barr and Bertram[1] in the nerve cells of the female cat, can be identified in the cells of several different tissues in the human female[2]. The method of 'nuclear sexing' is now a well-recognized technique of exceptional importance in the investigation of disorders of human sexual development. The technique has been applied to the study of human tumours and, provided that good histological preparations have been available, it has been found, in most cases, that sex chromatin was recognizable in the cells of tumours of female patients but not in those of males, that is, the tumour is of the same sex as the host[3-5]. The principal exception is in the case of teratomata, which are always of female nuclear sex if the host is female, but may be male or female if the host is male[3-6]. Two alternative hypotheses have been postulated in explanation of this anomaly: one presumes that the tumour arises by parthenogenesis of haploid germ cells followed by endomitosis to restore the diploid chromosome number; the other supposes that the tumour arises by conjugation of two haploid germ cells.

In addition to teratomata the basal cells of the epidermis and the basal-cell tumours of the skin have been found to be exceptional in this respect. Weinmann, Meyer and Marwah[7] found difficulty in diagnosing the nuclear sex of basal cell tumours of the skin. In a series of 11 such tumours from male patients a sex chromatin-like particle could be identified in many of the parenchymal neoplastic cells and also in many of the cells of the adjacent normal epidermis. It was not suggested that this particle indicated a sex reversal in these tumours, but rather that the chromatin structure of the cell was altered during oncogenesis. A similar explanation was invoked by Tavares[8]; he examined "undifferentiated cell carcinomata", a group of tumours regarded by him as separate from those showing evidence of differentiation, and found that of 18 tumours in males two appeared to be female; while of 35 tumours in females six appeared to be male and in 18 instances the result of sexing the tumour was equivocal. Sachs and Danon[9], on the other hand, reported that the basal cells of the epidermis were devoid of sex chromatin and suggested that this was due to the "high frequency of mitosis" in this site. In view of the discrepancies reported in these cells and in their tumours it was decided to investigate a fresh series of specimens.

The most critical method of determining the presence or absence of sex chromatin in tissue cells is to use these cells alone to determine the sex of the patient from whom the tissue was obtained. It is essential for this type of work that good histological preparations and suitable staining methods should be used. All the material used in this study was fixed in formalin, paraffin sections were cut at 5μ and were stained in hæmatoxylin and eosin, the staining being controlled by microscopical examination during differentiation.

A series of 37 sections of skin taken from the routine surgical material of the hospital was examined. The 'nuclear sex' was determined, first by examination of 100 basal cells and secondly by examination of 100 spinous cells of the overlying epidermis. Nineteen of the patients were female and eighteen male, in every case the 'sex' of the basal cells, the 'sex' of the spinous cells and the apparent morphological sex of the patient were congruous.

A consecutive series of 24 basal cell carcinomata were examined. The sections were first reviewed under the low power of the microscope to confirm the histological diagnosis and to select an area of tumour in which the cells were not too closely packed together by the surrounding tissues. The 'nuclear sex' was then determined by examination of 100 tumour cells followed by the examination of 100 cells in the adjacent epidermis. Nine of the patients were male and fifteen female, in every case the 'sex' of the tumour, of the skin and of the whole patient were identical.

Repeated examinations were made of many of the slides at different times; in no instance were anomalous results obtained.

These observations indicate that there is no peculiarity in the basal cells nor in their tumours, and that, given good histological preparations, sex chromatin can be identified in these structures as in all others. This point was made by Sohval and Gaines[10], who examined 134 tumours from female patients and found sex chromatin in only 33, and is of the utmost importance especially when cytological examination of cells and cell nuclei is used in the investigation of cases of sexual abnormality.

I am indebted to Miss C. D. M. McDougall and Mr. S. E. Wright, who were responsible for the excellent histological preparations which made this work possible.

Effect of 2,4-Dichlorophenoxyacetic Acid on Pectin Methylesterase in Tobacco Pith Sections

The hypothesis by Bennet-Clark[1] that the degree of methyl esterification of the pectic substances of plant cell walls would have a marked effect on the plastic and elastic properties of such walls has directed attention to the role of the pectic substances in auxin-controlled extension growth. Ordin, Cleland and Bonner[2] have demonstrated that the methylation rate of pectins in the walls of coleoptiles is increased by auxin, and Tagawa and Bonner[3] have shown that the effect of various cations and of auxin on the physical properties of the walls are consistent with Bennet-Clark's hypothesis.

Recently, it has been shown[4,5] that the auxins, indoleacetic acid, 2,4-dichlorophenoxyacetic acid and α-naphthalene acetic acid may control the adsorption of pectin methylesterase to cell-wall fractions prepared from tobacco pith or Jerusalem artichoke tubers. The auxins, up to an optimal concentration of about 10^{-10} M, increased the amount of enzyme adsorbed. It was proposed that the extent of methyl esterification of the pectic substances of the walls in elongating cells could be controlled by auxin-induced adsorption of pectin methylesterase.

Evidence has now been obtained for an auxin-controlled mechanism of adsorption of pectin methylesterase in intact disks of tobacco pith. When pith from *Nicotiana tabacum* v. *glauca* was placed in a solution of 0·5 per cent pectin and 0·1 M sodium chloride, considerable pectin methylesterase activity could be measured. The rate of hydrolysis of ester bonds of the pectin (measured by the rate of acid production) gradually increased until a steady rate was reached. Vacuum infiltration of the disks with the pectin assay solution did not reduce the time for the attainment of the steady rate, indicating that the initial change of rate was not due to penetration of pectin into the disks.

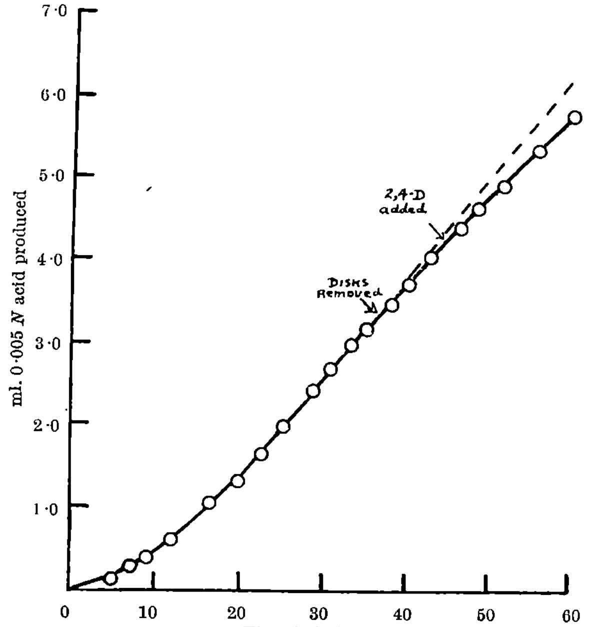

Fig. 1. Hydrolysis of pectin by pectin methylesterase extracted from tobacco pith disks by the assay solution. (0·5 per cent pectin; 0·1 M sodium chloride)

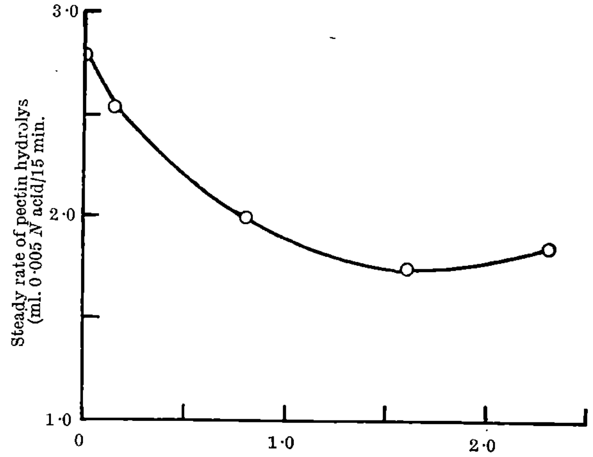

Fig. 2. Effect of 2,4-dichlorophenoxyacetic acid on the extraction of pectin methylesterase from tobacco pith disks. (0·5 per cent pectin; 0·1 M sodium chloride)

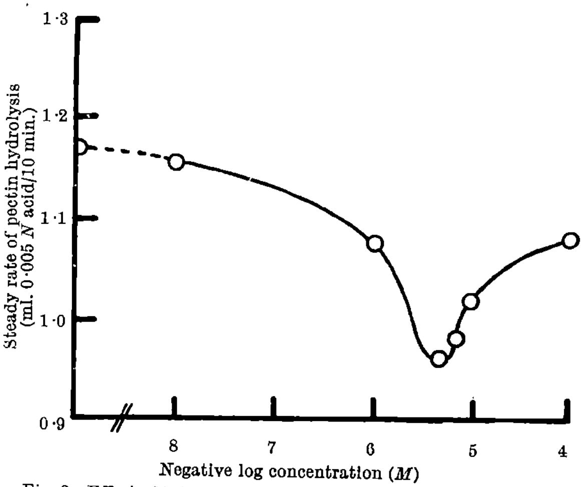

Fig. 3. Effect of 2,4-dichlorophenoxyacetic acid on the extraction of pectin methylesterase from tobacco pith disks. (0·5 per cent pectin; 0·2 M sodium chloride)

Removal of disks from assay solution after the steady rate had been reached showed that about 90 per cent of the measured pectin methylesterase activity remained in solution. When sodium chloride was omitted, no pectin methylesterase was extracted.

If disks which had been in pectin and sodium chloride until a steady rate of acid production was reached were transferred to a fresh assay solution, a second lot of pectin methylesterase was extracted. Again a steady rate was reached. The steady rate, therefore, represented an equilibrium position between enzyme in the assay solution and enzyme bound in the disks. The enzyme in the disks did not contribute substantially to the rate at which the pectin of the assay solution was de-esterified. This can be seen from Fig. 1, which also shows that 2,4-dichlorophenoxyacetic acid had no significant effect on the activity of pectin methylesterase when free in solution.

When 2,4-dichlorophenoxyacetic acid was included in the assay system, the steady rate of pectin hydrolysis by the disks was greatly affected. In Fig. 2 the steady rates are plotted against concentration of 2,4-dichlorophenoxyacetic acid. Fig. 3 shows results for a wide range of concentrations of 2,4-dichlorophenoxyacetic acid and 0·2 M sodium chloride as the extracting solution.

It is suggested that 2,4-dichlorophenoxyacetic acid shifts the equilibrium position for partitioning the enzyme between the disks and the external medium by controlling the binding of pectin methylesterase to sites in the cell wall.

These observations strengthen the hypothesis for the relation between auxin-controlled extension growth and auxin-controlled adsorption (inactivation) of pectin methylesterase[4,5]. Evidence for the heterogeneity of pectin methylesterase and adsorption sites in cell walls, a mathematical treatment of the adsorption process, and full details of experiments outlined here will be published elsewhere.

Acknowledgments are due to Dr. R. N. Robertson for helpful advice and criticism and to Miss Sue Ingles for technical assistance.

Radicle Elongation of *Pseudotsuga menziesii* in Relation to Light and Gibberellic Acid

One of the characteristics of the 'bakanæ' disease of rice (which is caused by *Gibberella fujikurio*, the fungus which produces gibberellic acid) is its ability to stimulate adventitious root formation. Attempts to increase root development with artificially supplied gibberellic acid, however, have almost invariably failed; indeed, it has been claimed that root elongation is inhibited by the gibberellins[1,2]. With few exceptions, observations of root effects have been incidental to studies of shoot development and it is possible, therefore, that observed effects on roots are indirect and result from a re-distribution of material within the plant from root to shoot.

In view of the uncertainty relating to the influence of gibberellic acid on root elongation, it seemed of interest to test its effect directly, on material uncomplicated by the presence of an active shoot system. In the experiments reported here, elongation of the radicles emerging from germinating Douglas fir seed before the onset of cotyledon growth was used to measure the effect of the chemical. At the same time, a possible interaction between gibberellic acid and light was investigated.

Preliminary tests employed a light treatment (continuous light at 4,000 lux and continuous darkness) and five gibberellic acid treatments (0, 3, 10, 30 and 100 p.p.m. applied in de-ionized water to filter paper and used as a growth medium). Root elongation over a 24-hr. period was markedly inhibited by exposure to light, but in both light and darkness there was a stimulation by low concentrations (about 3 p.p.m.) of gibberellic acid. To investigate these effects more precisely, seeds were germinated at 20° C. in Petri dishes and treated with gibberellic acid in concentrations of 0, 0·01, 0·10, 1·00 and 5·00 p.p.m. Again, two light treatments (continuous light and continuous darkness) were employed. Radicle elongation-rate over a 24-hr. period was measured on 45 roots from each treatment, chosen so that three size classes (<5 mm., 5–10 mm. and >10 mm. in initial length) were equally represented.

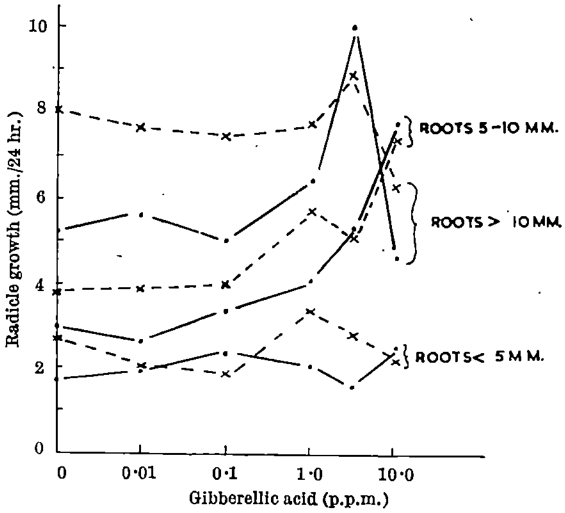

Fig. 1. The effect of light and gibberellic acid on radicle elongation of *Pseudotsuga menziesii* as related to initial root length. × --- ×, Growth in darkness; ● — ●, growth in light

In Fig. 1, mean growth-rates are plotted against acid concentration by size class and light treatment. Roots greater than 5 mm. in initial length show a marked response to gibberellic acid treatment, the optimum concentration shifting from 10 p.p.m. to 5 p.p.m. with an increase in initial length of root.

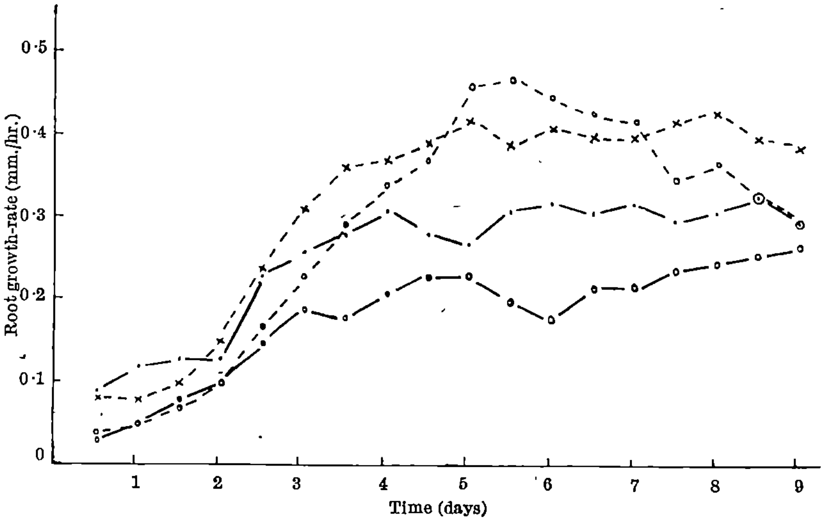

Fig. 2. The effect of light and gibberellic acid on the time course of radicle elongation in *Pseudotsuga menziesii*. ● — ●, dark; × -- ×, dark + gibberellic acid; O — O, light; O -- O, light + gibberellic acid

The inhibiting influence of light is also demonstrated, the effect increasing with increasing root size; and there is an apparent interaction between light and gibberellic acid. The response to optimal concentration of gibberellic acid is greater in light than in darkness and the inhibiting effect of light on the growth-rate is more than overcome.

Fig. 2 presents the results of another experiment in which the course of root growth in response to 8 p.p.m. gibberellic acid was followed over a period of time. Again there is a marked response to acid treatment though it is initially much greater in light- than in dark-grown roots.

In spite of certain difficulties in interpretation of these results, it is clear that gibberellic acid can stimulate root elongation. It is also apparent that light inhibits root elongation, and that, under some conditions, gibberellic acid and light interact. Nevertheless, the results presented are not incompatible with Lockhart's[3] contention that the action of artificially supplied gibberellic acid is specific on elongation and not directly connected with light responses. With the view of analysing the light inhibition of root elongation, studies of its action spectrum have been initiated. There are preliminary indications that the light-reaction peaks at 5400–5800 A. with subsidiary peaks at 3800 A. and 6600 A. A full report on this work will be published elsewhere.

Partial Inhibitory Effect of *Plistophora culicis* on the Sporogonic Cycle of *Plasmodium cynomolgi* in *Anopheles stephensi*

DURING some experimental work carried out on the cytology of early oocysts of *Plasmodium cynomolgi* in *Anopheles stephensi* an interesting observation was made. Three batches of laboratory-bred *Anopheles stephensi* were fed on a rhesus monkey (*M.* 172) infected with *P. cynomolgi*. Dissections of 4–10 mosquitoes on each subsequent day showed that the first and third batches of these mosquitoes were also infected with a microsporidian (*Plistophora culicis*). (Such infections have previously been described by Garnham[1] and Canning[2].) Nearly 50 per cent of the dissected mosquitoes showed a moderate infection of *P. culicis* in the first batch, a light infection of about 5 per cent in the second batch, and approximately 100 per cent with heavy infections of *P. culicis* in the third batch. A poor rate of infection by *P. cynomolgi* was found in the first and third batches of *A. stephensi,* and this was considered due to the partial inhibitory influence of *P. culicis* on the development of the oocysts in these mosquitoes. This view was supported by the findings of good oocysts counts in the mosquitoes dissected from batch two in which the *P. culicis* infections were very light.

Plistophora culicis had not only invaded the fat bodies and Malpighian tubules, but also in many mosquitoes the whole surface of the mid-gut was covered by the microsporidian. The inhibitory influence on the development of *P. cynomolgi* in such insects was primarily reflected in a low oocyst count; in most mosquitoes only one or two oocysts could be found on each mid-gut. The growth of these oocysts was also retarded. Thus five-day-old oocysts measured 19μ in diameter compared with the normal oocyst size 21μ seen in mosquitoes uninfected with *P. culicis* after this time. Seven-day-old oocysts measured only 55μ in diameter compared with the normal size of 60μ. The diameter of mature oocysts in the mid-guts heavily infected with *P. culicis* was only 84μ compared with the usual 90μ. The highest rate of infection with *P. cynomolgi* oocysts in the mosquitoes concomitantly infected with *P. culicis* was 20 per cent and the lowest 10 per cent. Many degenerating oocysts were seen.

One may conclude that the partial inhibitory effect of *Plistophora culicis* on the sporogonic cycle of *P. cynomolgi* in these batches of *A. stephensi* may be due to the following possibilities: (1) The scarcity of essential nutriments in the body of the host may be responsible for the retarded growth and degeneration of fully developed ookinetes and young oocysts. These essential substances were presumably taken up by *P. culicis* for its own development. (2) Many specimens devoid of oocysts showed the whole surface of the mid-gut covered with *P. culicis*. The presence of this microsporidian may have prevented the penetration of ookinetes through the stomach wall and resulted in the degeneration of these 'vermicules' inside the lumen. (3) The heavy infection of Malpighian tubules with *P. culicis* may cause abnormality in their function. Afterwards the deposition of toxic substances might interfere with the development of oocysts and sporozoites of *P. cynomolgi* in the insect host.

Isolation of a Soil Coccus capable of utilizing 'Tween 80' as a Sole Source of Carbon

IT is interesting that some organisms can utilize as their source of carbon a synthetic substance such as 'Tween 80' (polyoxyethylene sorbitan mono-oleate). My collaborators and I[1] have proved that tubercle bacilli can utilize 'Tween 80' as a sole source of carbon, and Yamane *et al.*[2] then devised a simple and practicable 'Tween'-agar medium for tubercle bacilli containing 'Tween 80' as a main source of carbon. I wished to investigate[3] the details of the mechanisms of 'Tween' metabolism, but tubercle bacilli are not suitable for this purpose because their growth is so slow, their endogenous substrates are too abundant[4], and experiments with the bacilli can be dangerous. I therefore decided to try to isolate bacteria more suitable for the purpose from the soil.

The isolation was carried out on Yamane–Minami–Yasui agar[1], which contained 'Tween 80' as a sole source of carbon. After incubating the supernatant of soil suspension at 37° C. for 24 hr., a few bacterial colonies were developed, among which there was a coccus. This organism was a Gram-negative coccus

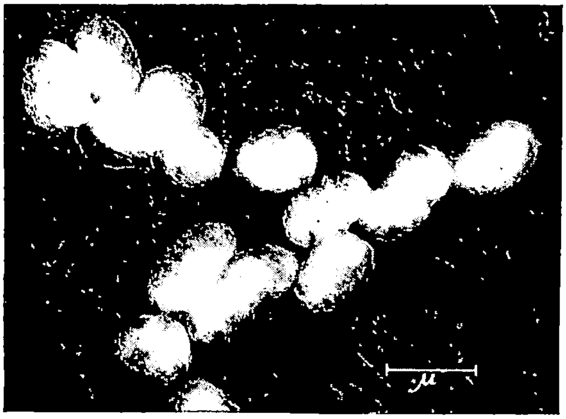

Fig. 1. Electron micrograph of the newly isolated coccus grown in a synthetic medium containing 'Tween 80' as a sole source of carbon for 6 hr. Shadowed with chromium. Flagella-like structures around the cell periphery were observed. The electron-transparent regions immediately inside the cell wall were observed only in the cells in the logarithmic growth phase; their nature and the mechanism of formation are now under investigation

of 0·5–1·2μ in diameter, occurring singly, in pairs or in clumps. It was non-motile, but flagella-like structures were observed by electron microscopy (Fig. 1). Growth occurred well on nutrient agar, blood agar and especially well on 'Tween'-agar[2] under aerobic conditions, developing smooth, flat and greyish-white colonies. Sugar fermentation was very poor: glucose, arabinose, xylose and galactose gave slight acid formation only after long incubation (2–4 days). Simmons's citrate test was positive; urease was negative. Nitrates were not reduced to nitrites; catalase was positive; indole was not formed; gelatin was not liquefied within 2–3 weeks.

In general, taxonomic characteristics of this organism resembles closely *Neisseria catarrhalis* (Frosch and Kolle) Holland[5], but it differs in its habitats and some of its sugar fermentations. So this organism belongs to the Micrococcaceae rather than to the Neisseriaceae, but no description corresponding to this organism has been found in Bergey's system[5]. I believe it is a new strain of Micrococcaceae, and propose the name *Micrococcus tweenis* for it. (The details of the taxonomic description will be presented elsewhere.)

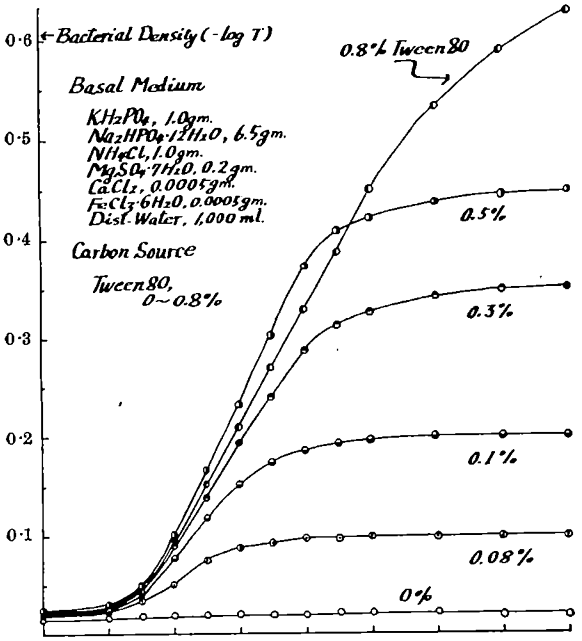

Fig. 2. Growth curves of a newly isolated coccus grown in synthetic media containing 'Tween 80' as sole source of carbon. The concentration of 'Tween 80' was varied from 0·08 to 0·8 per cent. The culture was shaken at about 55 strokes per min. at 87° C.

Fig. 2 shows the growth-curves of this organism grown in synthetic media[1] containing 'Tween 80' as a sole source of carbon. The higher the concentration of 'Tween 80' used, the more abundant was the growth; and if no 'Tween 80' was added, no growth was observed.

'Tween 80' (0·05–0·8 per cent) stimulated the oxygen uptake of the cell suspension prepared from an 18-hr. culture grown on 'Tween'-agar medium. The oxygen uptake was also stimulated vigorously by such long-chain higher fatty acids and substances related to the tricarboxylic acid cycle such as oleate, stearate, palmitate, acetate, succinate, malate, fumalate, glutamate and aspartate, and to some extent by citrate and lactate.

Details of investigations with this organism will be reported elsewhere.

Polyploidy in Bluebells

IN my preliminary account[1] on polyploidy in bluebells (*Endymion nonscriptus* (L.) Garcke, and *E. hispanicus* (Mill) Chouard), I mentioned that some of the huge forms in gardens which I found to be triploids looked very much like the central one of Turrill's coloured figures[2]. Owing to the absence of any caption on Turrill's figures, I was led to take this huge central figure as the putative hybrid between the two species which Turrill mentions in his text. A few months after my publication, Turrill[3] explained his figures and pointed out that the central figure was *E. hispanicus*; he also suggested that since I did not examine his own material cytologically the material which I examined and found to be triploid might be different from his in ploidy.

I therefore asked for some of his material of *E. hispanicus*, most of which on cytological examination I found to be triploid. Thus it seems there is little doubt but that the huge bluebell represented by the central figure of Turrill's coloured figures is the triploid of *E. hispanicus* and not the ordinary (diploid) form.

Micro-fungi in Pine Litter

ALTHOUGH a certain amount of work has been carried out on the microbiological characteristics of horizons in podzol soils, there is as yet little relating to the subdivisions of the A_0 horizon. In any such work there are obvious advantages in studying litter derived from a single species. Plantations of *Pinus sylvestris* have the added advantage that slow decomposition of the litter leads to the accumulation of a considerable A_0 horizon readily divisible into distinct layers. The A_0 horizon of forest soils can be subdivided in the following way : *L* layer, undecomposed litter ; *F* layer, decomposing but still recognizable litter ; *H* layer, amorphous humus. In cases of considerable accumulation the *F* layer may be further subdivided into *F*1, needles dark in colour, often still intact, and *F*2, needles greyish, fragmentary, compressed[1].

Samples of the *L*, *F*1 and *F*2 layers of the A_0 horizon of the podzol at Delamere Forest, Cheshire, were selected by inspection and transported to the laboratory in separate, sterile containers. Preliminary work with the standard dilution plate technique proved unsatisfactory, and records of the fungi on the needles were made therefore by two methods : (1) direct observation of freshly sampled needles ; (2) observation of needles rigorously washed to remove surface-borne spores and maintained on a nutritive medium for two weeks. The type of result obtained is shown in Table 1. The abundance of the different fungi is expressed as the percentage of the total number of needles on which each fungus was observed.

Table 1 demonstrates both qualitative and quantitative differences in the fungal populations of the three subhorizons investigated. Direct observation showed maximal fungal activity to occur on needles of layer *F*1. Numerous fruiting structures of several fungi not represented on nutritive media were also seen in this layer. In layer *L* only *Lophodermium pinastri* was regularly observed, but in layer *F*1 three species other than *Lophodermium* occurred with very high frequency. *Verticicladium trifidum* has been recorded by Hughes[2], but the *Helicoma* species will be described elsewhere as a new species, and isolate 1/6 will be described elsewhere as a new genus. The two new forms are darkly pigmented, and produce reticula on the needle surface from which the conidiophores arise. Layer *F*2 showed mutilated remains of these fungi, a result of the activities of mites and other microfauna. Basidiomycete mycelium was, however, observed most frequently in this layer.

The cultural method of isolation revealed several fungi not seen by direct observation. Certain of these, that is, *Antennularia*, sterile dark isolate 3/10 and *Fusicoccum* were seen to occur with decreasing frequency from layer *L* to layer *F*2, while there was a corresponding increase in the occurrence of *Trichoderma* and *Penicillium* species. Little indication of this clear-cut succession was obtained by the use of the dilution plate technique. The above data are based on isolations carried out in March 1957, but comparable differences between the subhorizons have been recorded for all other months.

Table 1

Method	Layer *L*		Layer *F*1		Layer *F*2	
	Spp. recorded	Frequency (per cent)	Spp. recorded	Frequency (per cent)	Spp. recorded	Frequency (per cent)
Direct observation	*Lophodermium pinastri*	35	*Helicoma* sp.	92	*Basidiomycete* mycelium	55
			Verticicladium trifidum	89		
			Isolate 1/6	89		
			Lophodermium pinastri	40		
			Basidiomycete mycelium	12		
Washing and plating on nutritive agar	*Antennularia* spp.	75	*Trichoderma viride*	75	*Trichoderma viride*	100
	Isolate 3/10	60	*Antennularia* spp.	40	*Penicillium* spp.	45
	Fusicoccum bacillare	35	*Penicillium* spp.	25	*Antennularia* spp.	5
	Trichoderma viride	35	Isolate 3/10	10		
			Fusicoccum bacillare	10		

I wish to express my thanks to Prof. A. Burges and Dr. D. Parkinson for their guidance during this work, which was carried out during the tenure of an Agricultural Research Council Research Studentship.

Protogynous Hermaphroditism in *Coris julis* L.

Coris julis L. and *C. giofredi* Risso have long been regarded as separate species, although Steindachner[1] claimed *julis* to be the male and *giofredi* the female individuals of the same species. In the Bay of Naples Lobianco[2] found mature male and female individuals both in *C. julis* and in *C. giofredi* and therefore rejected Steindachner's hypothesis of sexual dimorphism in *Coris*.

Work on this subject was resumed in the summer of 1956 following reports of transformation of *giofredi* into *julis* individuals in the basins of the Leghorn Aquarium (Razzauti). As hermaphroditism has been shown to be widespread among teleosts[3], researches were undertaken upon the hypothesis of the existence of false gonochorism[4] in *Coris*.

Statistical and histological investigations were conducted on 329 samples taken during August 1956–January 1957 from populations living at a depth of between 8 m. and 30 m. in the vicinity of Leghorn.

Typical, fully grown individuals in the *julis* livery have a mean length of 14·81 ± 0·32 cm. and they are distinguished by a marked prominence of the first three rays of the dorsal fin and by a prominent tooth at the proximal end of each upper jaw. Their colours are very bright: the dorsal region is blue-green, a long deep orange band runs from the opercular region to the tail and a short black strip extends under it from the attachment of the pectoral fin to a region below the eleventh dorsal ray. The sides of the ventral region are white or shaded with light blue.

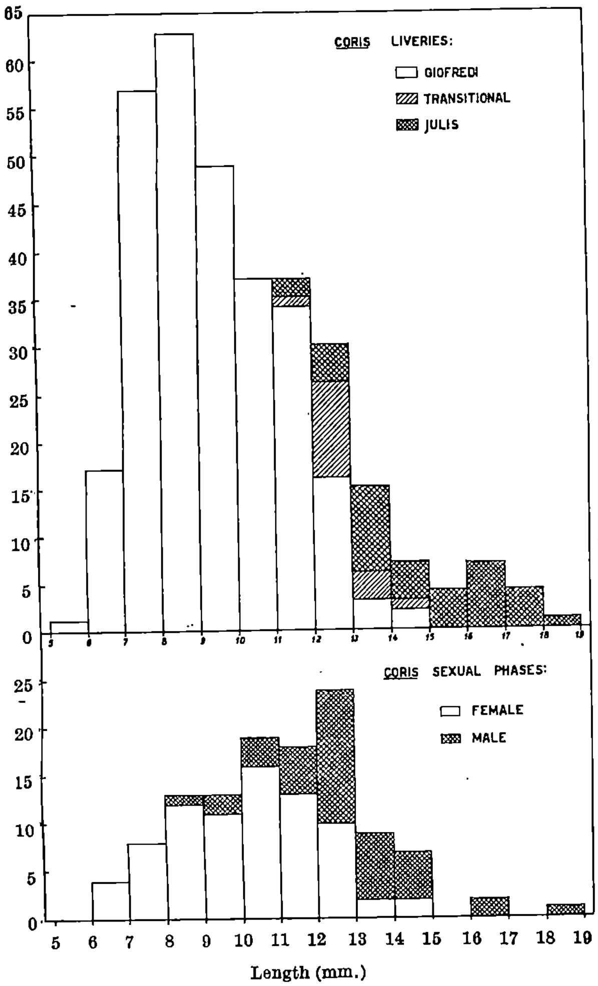

Fig. 1. Frequencies of *Coris* individuals in the different liveries (above) and in male and female phase (below) at various lengths (in millimetres)

Conspicuous black and red spots are evident between the first three rays of the dorsal fin.

Individuals in the *giofredi* livery have a mean length of 9·29 ± 0·57 cm. The above characters are missing, the dorsal region is brown and a golden band is visible on each side of the ventral region.

Intermediate characters are found in individuals with a mean length of 12·76 ± 0·10 cm.: the first *julis* character which appears among smaller transition individuals is a prominence of the first three dorsal rays, and the teeth at the ends of the upper jaws are the last character to be established in *julis* individuals (Fig. 1, above).

Gonads are reduced during the months from August to January and therefore individuals were sexed by histological methods. The examination of 118 paired gonads showed that smaller specimens (mean length 10·14 ± 0·22 cm.) are females, bigger specimens (mean length 12·75 ± 0·30 cm.) are males. A few big individuals in the *giofredi* livery (15·9 per cent) are nevertheless males. Transitional individuals are mostly (66·6 per cent) males (Fig. 1 below). Thus the livery appears to be partly independent of sex-conditions. Only a few specimens showed signs of a preceding female phase (small and degenerating oocytes) in gonads where most germinal cells were beginning spermatogenesis. These individuals (which were classified in the male phase) were either large sized *giofredi*, transition forms or small sized *julis*. Young individuals were all females and they showed the *giofredi* livery.

No regional preference of male and female germ cells in the reversing gonad has been detected so far, and the developing male germ cells rapidly replace oocytes after their expulsion or degeneration. For this reason gonads appear generally in pure female or male conditions.

Investigations are now being conducted with samples both from Leghorn and from the north-western coast of Sardinia in order to study the whole annual cycle and sex variation in *Coris*. Nevertheless the following conclusions can be drawn from the present results: (*a*) *C. giofredi* and *C. julis* are the younger and older individuals of a single protogynous hermaphrodite species (or intersexual species according to D'Ancona's terminology) that must be named as *Coris julis* L.; (*b*) since the sex change from female to male phase runs roughly parallel to the change of the livery, the female and the male phases in most individuals (but not in all of them) are represented by the *giofredi* and the *julis* livery respectively; (*c*) as a supposed 'sex dimorphism' is widespread among members of the Labroid family, it may indicate the existence of false gonochorism among other species of the group.

Size Variation in *Entamoeba histolytica*

The human bowel is inhabited by amoebæ with the morphology of *Entamoeba histolytica*, but of differing mean size. The larger of these can be tissue-invading pathogens or may, usually in a smaller form, remain as a commensal in the bowel[1]. Further, there is considerable overlap in size range, at least in the commensal form, with a still smaller amoeba of similar morphology which has variously been known as *E. hartmanni* Prowazek, 1912; *E. histolytica hartmanni* Hoare, 1949; or as the small race of *E. histolytica* of Dobell, 1919. Of these views, the latter two have been the most widely favoured, but the work of Burrows[2] has indicated that there are morphological differences which suggest that the small amoeba should be considered a distinct species. However, there is, even on Burrows's criteria, still overlap with the large form, certain features being found sometimes in one and not in the other and vice versa.

Recently, we encountered a stool in which there were, fairly obviously, two different sizes of amoebæ, both with *histolytica* morphology. In a culture, this difference continued over a period of months. Fig. 1 shows a histogram based on the diameters of 600 live trophozoites from such cultures and shows a superimposed normal distribution from the hypothetical mean (4·6 micrometer units—10 micrometer units = 25·75μ) and its standard deviation (1·89). The

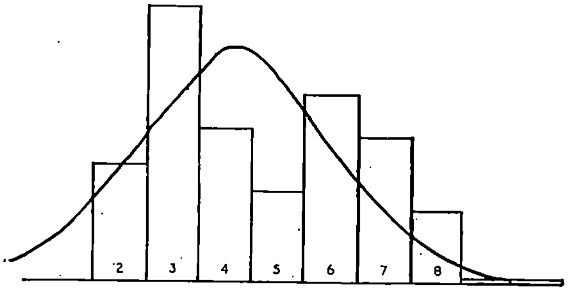

Fig. 1. Histogram of line *Z* based on the diameter of 600 live trophozoites with a superimposed normal curve based on the hypothetical mean and its standard deviation (10 micrometer units = $25 \cdot 75 \mu$)

bimodal curve actually found indicates that there were clearly two different types present.

In the course of experimental work to be reported elsewhere on the isolation of amoebæ from human liver abscesses, we noted that the size of these amoebæ is apparently governed by the type of bacterial associate provided. Fig. 2 shows three frequency polygons showing the size of lineal descendants from the same specimen (*L*) of liver pus. *L*.68 (mean diameter $20 \cdot 8 \mu$; standard deviation $3 \cdot 0$) was isolated in culture with *Clostridium welchii* as associate; *L.M.* (mean diameter $15 \cdot 4 \mu$; standard deviation $2 \cdot 9$) was isolated by the provision of a mixed flora *M*. The difference in size is significant, being more than three times its standard error ($P < 0 \cdot 001$). When, however, these lines were mixed and cultured together the resultant curve was unimodal (mean diameter $16 \cdot 9 \mu$; standard deviation $2 \cdot 3$) and lay between the two parent curves, showing that the difference in size was due to environmental effects.

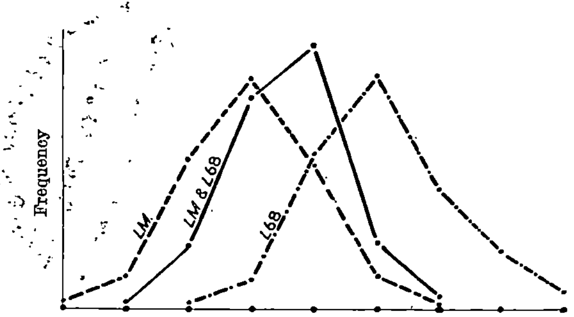

Fig. 2. Size-frequency polygons in lines *L*.68 and *L.M.* and in their combined culture *L.M.* and *L*.68, which gives a unimodal curve

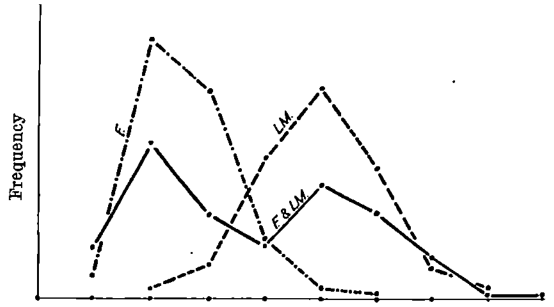

Fig. 3. Size-frequency polygons in lines *F* and *L.M.* and in their combined culture *F* and *L.M.*, which gives a bimodal curve indicating that *F* and *L.M.* segregate

We therefore mixed amoebæ which would be considered as 'large' and 'small' races. Fig. 3 shows the effect of culturing line *F* (mean diameter, $9 \cdot 3 \mu$; standard deviation $2 \cdot 1$) with its full associated flora, with line *L.M.* (mean diameter, $15 \cdot 4 \mu$; standard deviation $2 \cdot 9$), originating from the liver, but associated with a stool flora *M*. The mixture shows a significantly bimodal curve similar to that found with *Z*. An apparently commensal large line *B* (mean diameter, $19 \cdot 2 \mu$; standard deviation $3 \cdot 1$) when mixed with *F* also gave a bimodal curve.

It would thus appear that, although size can be varied by changing the bacterial associate of a line of 'large' *E. histolytica*, the 'small' race is genetically different and is distinguishable from the large when the two are cultured together in a single test-tube. This phenomenon is analogous to reproductive isolation in sexually reproducing organisms, a valid criterion for specific separation. This would suggest that the small amoeba with *histolytica* morphology occurring in human stools, and hitherto known as 'small race' or *E. histolytica hartmanni*, should be a separate species, *Entamoeba hartmanni* Prowazek, 1912.

Lapse-time Motion Picture Studies of Soil-burrowing Insects

During the past few years, studies of the movements of soil-burrowing insects have been made using radioactively tagged insects[1]. Originally, the method involved finding the position of maximum response of a manually operated portable Geiger tube and ratemeter, but later a machine was developed which would record automatically the movement of a radioactively tagged insect such as a wireworm[2]. The sensing element in this machine was a thyrode tube (Victoreen 1*B* 85), rotated about a vertical axis at the end of a fixed arm. Translatory movements of the axis of Geiger revolution were recorded on an operating surface by a stylus.

The possibility of using this machine for obtaining motion-picture studies of insect movements has been investigated. In effect, the wireworm, by means of the tag and the machine, was provided with a pencil. The movements of the pencil and machine were photographed, using lapse-time technique to give a speeded-up picture of the worm movements.

A wireworm was tagged and liberated in a tray of soil placed on the floor. A table was placed over the tray and the machine set on the table. A sheet of glass was placed over the machine. A piece of grease pencil was attached to the machine on the Geiger axis and held in contact with the under-surface of the glass by a spring. The path taken by the wireworm was thus traced on the lower side of the glass sheet (Fig. 1).

A 16-mm. ciné camera was mounted above the machine so as to view it through the glass sheet. The camera was equipped for solenoid-controlled

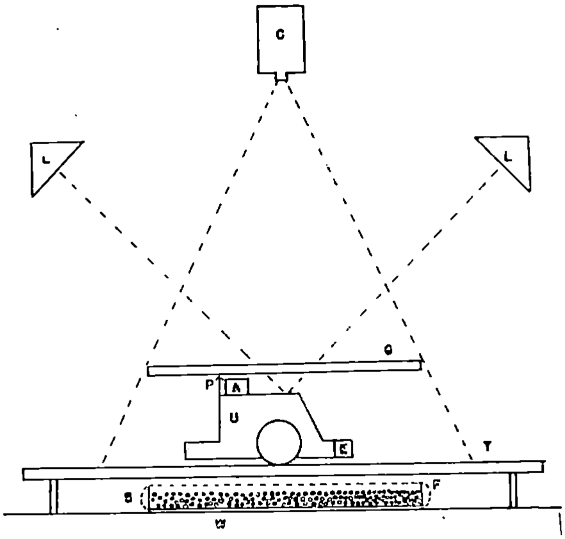

Fig. 1. Equipment used for lapse-time pictures. *C*, camera; *L*, lights; *G*, glass sheet; *P*, writing stylus; *U*, tracking unit; *T*, table; *S*, tray of soil; *F*, plastic moisture seal; *W*, tagged wireworm; *A*, clock; *E*, camera timing unit

single-frame exposures. The solenoid was operated by a clock-controlled microswitch mounted on the tracking unit. The exposure interval chosen was 30 sec. and pictures were taken over a 3-hr. period. The result was essentially a speeded up ciné film of the wireworm's movement in a period of 3 hr. (Fig. 2). The particular wireworm involved travelled at the rather high speed of 23 in./hr. As it turned out, the whole operation was rather abbreviated and the exposure interval chosen was too long. However, the short film obtained serves to demonstrate the value of the technique.

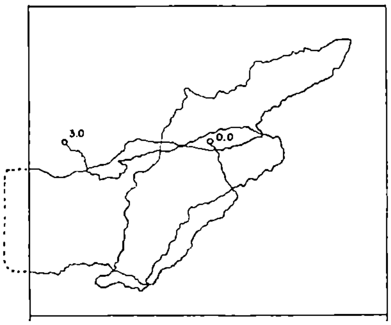

Fig. 2. Copy of the final trace obtained in lapse-time test. Figures give the time in hr. after the worm was introduced. The part of the trace indicated by a broken line was outside the field of view of the camera for a short time. Soil layer 15 in. × 22 in. × 1 in.

An Assemblage of Arthropod Remains from a Roman Occupation Site at St. Albans

IN the course of an excavation of a Roman occupation site at St. Albans, Hertfordshire, in 1955, a ditch was discovered which had been partly filled in, during the first century A.D., with a large quantity of organic material. Among this mass, bracken, grass, moss, leaves, twigs, seeds, etc., could still be recognized, and at one point it reached a depth of 7 ft. At least one wooden building had been erected on top of this; but when it had fallen into disuse the site had been levelled off by dumping clay and earth on it to a depth of about one foot. Afterwards a succession of substantial stone houses had been built, between the first and fourth centuries A.D., forming a succession of strata about 8 feet thick, which sealed this ditch-filling in an undisturbed state until the present time.

Among the organic material in this deposit there was found a colony of living earthworms (*Eophila oculata* Hoff.)[1] which may have persisted there since Roman times, and another interesting find was the large number of insect and other arthropod remains in quite a good state of preservation. Of about 60 specimens recovered, 40 could be identified at least to the family, and many to the genus, and, tentatively, to the species. The following is a shortened list of the specimens, identified as nearly as possible:

- Insecta
  - Dermaptera: *Labia minor* L. (many specimens)
  - Lepidoptera: *Arctia caja* L. (puparium)
  - Coleoptera
    - Carabidae:
      - *Clivina fossor* L.
      - *Nebria brevicollis* F. (several specimens)
      - *Feronia madidus* F.
    - Hydrophilidae:
      - *Megasternum obscurum* Marsh.
    - Histeridae:
      - *Hister* spp.
      - *Onthophilus striatus* Forst
      - *Abraeus granulum* Er.
    - Staphylinidae:
      - *Staphylinus* sp.

Fine structures such as setæ, wing scales of Lepidoptera, and tracheæ were well preserved, and although pigmentary colours had either blackened or faded, structural colours were as bright as ever. The ditch contents presented a very moist and strongly reducing environment, as shown by the presence of quantities of vivianite (a hydrated ferrous phosphate), and such conditions may be important for the preservation of chitinous arthropod parts.

The layer of clay and earth which had been dumped on top of the deposit had trapped an ecological assemblage of insects, etc., from which conclusions about the nature of the deposit may be drawn. First of all, it represents what one would expect to encounter in a refuse heap, with incidental species entering by chance from neighbouring grassland habitats. Insect remains were found at all levels in the deposit, although they were most plentiful in the upper part. This suggests that the deposit was accumulated during a fairly short period of time, a few years at the most, as the arthropod cuticle does not withstand prolonged weathering.

The species found in the lower levels suggest the presence of rotting vegetation ; but at the top large numbers of puparia of *Lucilia* and *Calliphora* (the bluebottle and greenbottle flies) indicated the presence of carrion and dung. It is interesting to note that the layer of clay which sealed the whole deposit was probably dumped on a day in late summer. The assemblage of species trapped immediately under it would suggest this, and also, although most of the fly puparia were vacated, a few clusters still contained remains of the immature flies.

For the identification of the specimens I am indebted to Mr. J. Balfour-Browne, and Dr. Owen Evans of the British Museum (Natural History), and Prof. F. E. Zeuner of the Institute of Archæology, University of London. I must also thank Mr. John Lunn of the Verulamium Museum for making the material available to me.

P. L. BRADLEY

A Case of Limitation of Phenotypic Variation

JINKS[1] suggests that where phenotypic variation is caused by a cytoplasmic system, the range of phenotypic expression attainable by the system would have quite definite limits imposed by the system itself (cytoplasmic limits) or, by the non-viability of phenotypes lying outside these limits (physiological limits). Cytoplasmic limits would result where further changes in cytoplasmic content are impossible, as when all cytoplasmic elements involved in the change are lost. Physiological limits would result where although more extreme changes in the cytoplasm are possible they would lead only to non-viable phenotypes. Jinks's results suggested a physiological basis to limits of variation obtained in *Aspergillus glaucus*.

Results from *Neurospora crassa* provide an example of a physiological limit to what appears to be cytoplasmically determined variation in the expression of a certain genotype. This genotype, which differs from the wild type by at least two genes, can show two different extremes of expression. At one extreme the culture forms no protoperithecia and instead produces many discrete areas of dark brown pigment (*bk* phenotype), while at the other extreme there is no sign of the dark pigment and weakly developed protoperithecia, which may be functional, are produced in limited parts of the culture (*S* phenotype). Stages intermediate between these two are formed. Cultures initiated from ascospores can show any stage in the range of phenotypes ; but subcultures derived from them almost invariably show intermediate or *S* phenotypes only. The *bk* phenotype can be induced to appear, or reappear in subcultures by certain treatment, when its appearance, and later disappearance after the treatment are typical of the behaviour of a dauermodification. This and other evidence suggest that the phenotypic range results from the interaction of the genotype with varying cytoplasmic states or conditions. Prolonged continuation of the treatment used for inducing the appearance of phenotype *bk* intensified formation of the brown pigment and was accompanied by a reduced growth rate and decreased viability. It appears that the induced cytoplasmic state led to the production of an abnormal phenotype, and that increase of the cytoplasmic state was limited by its causing an increasingly abnormal phenotype that led to the death of the cultures. In other words, there was a physiological limit to the extent to which the cytoplasmic state could be produced or selected for.

This view is supported by the results of a number of crosses involving these mutant strains. The crosses were first made after both strains had been subjected to the treatment leading to induction of phenotype *bk* and again seven months later with the same strains, but from stocks which had never been subjected to the induction treatment. At both times crossing was carried out by simultaneous inoculations of parent strains in the crossing tubes. There was a marked difference in the results obtained from the two sets of crosses, and these are illustrated in Table 1 with data from a typical cross.

Table 1. ASCUS TYPES PRODUCED BY CROSS 3–1 *A* × 5–7 *a*

	Ascus types	No. of asci
First crossing	*L L* *L L* *bk* *bk* — *bk*	2
	L L *L L* — *bk* — *bk*	2
	L L *L L* *bk* *bk* — —	3
	L L *L L* *bk* — — —	2
		9
Second crossing	*L L* *L L* *S* *S* *S* *S*	6
	L L *L L* *S* *S* *S* *bk*	3
	L L *L L* *S* *S* *bk* *bk*	1
		10

L, Wild type protoperithecia ; *bk*, *bk* phenotype ; *S*, intermediate and *S* phenotypes ; —, non-viable ascospore.

The cross was such that a 1 : 1 segregation of wild type to mutant would be expected. The mutant segregants in the progeny from the first crossing all had a strongly expressed *bk* phenotype, and 50 per cent of the mutant ascospores were non-viable. In the progeny from the second crossing 87·5 per cent of the mutant segregants showed an intermediate or *S* phenotype, while the remaining 12·5 per cent showed phenotype *bk*. There were no non-viable ascospores.

In all the crosses strong expression of phenotype *bk* was associated with high ascospore non-viability, while expression of phenotype *S* was associated with low ascospore non-viability. It appears that in the first series of crosses the cytoplasmic state of the progeny was such as to produce the extreme *bk* phenotype, and that in many of the ascospores this cytoplasmic state was intensified to beyond the limit of phenotypic viability. In the progeny of the second series of crosses a more normal cytoplasmic state existed and led to a considerable amount of protoperithecial formation in the mutant segregates, and complete ascospore viability.

This work was carried out largely at the Department of Genetics, University of Adelaide, while I held a New Zealand National Research Fellowship.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, February 10

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. M. Ginsberg: "Evolution, Development, Progress".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Herbert Report and the 1957 Act", opened by Mr. E. R. Wilkinson.

Royal Institute of Chemistry, London Section (at Norwood Technical College, Knight's Hill, West Norwood, London, S.E.27), at 7 p.m.—Dr. J. Green: "Recent Advances in the Chemistry and Function of the Vitamins".

Monday, February 10—Saturday, February 15

Department of Scientific and Industrial Research (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 10 a.m. daily—Exhibition—"Road Research in the Colonies".

Tuesday, February 11

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. A. R. Collins and Mr. D. R. Sharp: "Design and Construction of Concrete Roads Overseas".

Institution of the Rubber Industry, London Section (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. J. Mann: "Moulding". 7 p.m.—Mr. B. Ellis and Mr. G. N. Welding: "Characteristics of Accelerated Sulphur Vulcanization of Natural Rubber".

Royal Institute of Chemistry, London Section (joint meeting with the Sir John Cass College Chemical Society, at the Sir John Cass College, Jewry Street, London, E.C.3), at 6.30 p.m.—Prof. C. K. Ingold, F.R.S.: "An Organic-Chemical Contribution to the Inorganic Chemistry of Nitrous Acid".

Wednesday, February 12

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Gavin de Beer, F.R.S.: "The Inhabitants of Switzerland".

University of London (at Guy's Hospital Medical School, St. Thomas's Street, London, S.E.1), at 5 p.m.—Prof. C. D. Waddington, F.R.S.: "Evolutionary Adaptation to Environmental Stress".*

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—General Meeting.

Bedford College (at Regent's Park, London, N.W.1), at 5.15 p.m. —Dr. D. M. MacKay: "The Brain as an Information System".*

Institute of Physics, Education Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Discussion on "The Graduateship Examination". Speakers: Prof. J. G. Wilson, Mr. A. E. De Barr Prof. M. R. Gavin, Mr. J. Yarwood and Mr. N. Clarke.

Cement and Concrete Association (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m. —Dr. S. Champion: "Grouted Concrete Construction".

Institution of Electrical Engineers (at the Central Hall, Westminster, London, S.W.1), at 6 p.m.—Mr. R. Ledger: "The Electrification of Railways" (Faraday Lecture prepared by the late Mr. G. H. Fletcher).

Society of Chemical Industry, Food Group—Nutrition Panel, (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Third Meeting on "Some Nutritional and Allied Problems Confronting the Food Manufacturer". Dr. C. G. Sumner and Dr. F. Aylward: "Emulsifying and Dispersing Agents".

British Association of Chemists, London Section (at the Wellcome Building, 183 Euston Road, London, N.1), at 7 p.m.—Assistant Divisional Officer Dennett (London Fire Brigade): "Fire Prevention".

Radar Association (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 7.30 p.m.—Sir Robert Watson Watt, F.R.S.: "The Early Days of Radar".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "Science in General Education". Speakers: Dr. A. W. Barton, Mr. Richard Fort, M.P., and Sir Frank Ewart Smith, F.R.S.

British Psychological Society, Social Psychology Section (at Birkbeck College, Malet Street, London, W.C.1), at 8 p.m.—Papers on "Recent Developments in Advertising". Dr. Donald Melvon: "Motivation Research"; Dr. N. F. Dixon: "Sub-threshold Advertising".

Thursday, February 13

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. B. C. Abbott, Dr. A. V. Hill, F.R.S., and Mr. J. V. Howarth: "The Positive and Negative Heat Production Associated with a Nerve Impulse".

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. H. F. C. Crick: "The Nucleic Acids".* (Further Lectures on February 20 and 27.)

University of London (in the Hatton Lecture Theatre, Queen Mary College, Mile End Road, London, E.1), at 5.30 p.m.—Prof. M. W. Humphrey Davies: "Electrical Engineering in the Future" (Inaugural Lecture).*

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. H. L. Cox: "The Application of the Theory of Stability in Structural Design".

Society of Chemical Industry, Microbiology Group (in the Department of Botany, Imperial College, London, S.W.7), at 6.30 p.m. —Meeting on "The Enzymic Degradation of Carbohydrates".

Chemical Society (in the Large Chemistry Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 7.30 p.m.—Prof. B. Lythgoe: "Some Recent Advances in the Chemistry of the Vitamins D" (Tilden Lecture).

Friday, February 14

Institute of Physics, Non-Destructive Testing Group (at 47 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. E. L. Ripley: "The Analysis of Wreckage in Aircraft Accident Investigation".

Antiquarian Horological Society (at the Science Museum, South Kensington, London, S.W.7), at 7 p.m.—Mr. W. J. Gazeley: "Clock Escapements".

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Mr. F. W. Thomas: "Fine Chemicals in the Textile Industry".

British Glaciological Society (in the Geology Department, The University, Oxford), at 8.30 p.m.—Mr. W. H. Ward: "Glaciology and Mountaineering".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. J. Z. Young, F.R.S.: "The Structure of Cells".

Saturday, February 15

Biochemical Society (in the Beveridge Hall of the Senate House, University of London, W.C.1), at 10.30 a.m.—Symposium on "Glutathione".

British Psychological Society (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Dr. Desmond Morris: "An Analysis of Paintings and Drawings by Chimpanzees".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Secretary (graduate of a British university, preferably in science or engineering, with some experience of industry) to the University Appointments Board—The Registrar, The University, Liverpool (February 15).

Physicist, Senior grade (with an honours degree in physics and previous experience in hospital physics, preferably in the application of radioisotopes to clinical problems), in the Isotope Laboratories —The Personnel Officer, St. Thomas's Hospital, London, S.E.1 (February 15).

Lecturer (Grade I or II) in Applied Mathematics—The Registrar, The University, Bristol 8 (February 21).

Lecturer or Assistant Lecturer in the Department of Aeronautical Engineering—The Secretary and Registrar, The University, Southampton (February 22).

Lecturer or Assistant Lecturer in the Department of Zoology—The Secretary and Registrar, The University, Southampton (February 22).

Lecturer (preferably with experience with electrical machines and an interest in physical phenomena in machines) in the Department of Electrical Engineering—Prof. A. Tustin, Electrical Engineering Department, Imperial College, London, S.W.7 (February 22).

Scientific Officer (with an honours degree in zoology) in the Nematology Department—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (February 22).

Senior Lecturers or Lecturers (2) in Physics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, February 28).

Chairs of Philosophy, Biochemistry, Pharmacology, Agriculture and Mechanical Engineering in the University of Ceylon —The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Ceylon, March 1).

Lecturers or Assistant Lecturers (2) in the Department of Physics—The Secretary and Registrar, The University, Southampton (March 1).

Tutorial Research Student in Mathematics (Pure or Applied) —The Principal, Royal Holloway College, Englefield Green, Surrey (March 1).

Farm Demonstrator (with a degree in agriculture or an honours degree in pure science followed by an adequate postgraduate qualification in agriculture, and preferably with some training in field experimentation), for duties which will include farm classes on the University Farm to undergraduate and postgraduate students—The Secretary, School of Agriculture, The University, Cambridge (March 5).

Lecturer or Assistant Lecturer in the Department of Philosophy—The Secretary and Registrar, The University, Southampton (March 8).

Lecturer (with appropriate qualifications in chemistry, and preferably a working knowledge of geology and mineralogy) in Geology (Geochemistry)—The Secretary, The University, Edinburgh (March 8).

Lecturer in Geology at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 10).

Lecturer in Physiology—The Secretary, The Queen's University, Belfast (March 15).

Research Assistants (2) (with research experience) in the Department of Theoretical Physics, for special research in fundamental particle and nuclear physics—The Registrar, The University, Liverpool (March 15).

Lecturer in Technical Mathematics—The Secretary, The University, Edinburgh (March 28).

Lecturer in Archæology; Assistant Lecturer in Social Anthropology and a Demonstrator in Physical Anthropology—The Secretary of the Appointments Committee, Faculty of Archæology and Anthropology, The University, Downing Street, Cambridge (March 31).

Lecturer or Assistant Lecturer in the Department of Electronics—The Secretary and Registrar, The University, Southampton (March 31).

Imperial Chemical Industries Research Fellows in Chemistry, Physics, Engineering, Pharmacy, Chemotherapy and related subjects—The Secretary, Academic Council, Queen's University, Belfast (April 1).

Professor and Head of the Department of Dairying—The Dean, Faculty of Agriculture, University of Alberta, Edmonton, Alberta, Canada (April 1).

Imperial Chemical Industries Fellows for research in Physics, Chemistry, Colloid Science, Biochemistry, Engineering, Metallurgy, Pharmacology, Chemotherapy or related subjects—The Secretary-General of the Faculties, The Old Schools, The University, Cambridge (April 30).

Lecturer in Fuel Technology and Chemical Engineering—The Registrar, The University, Sheffield (May 1).

Lecturer in Forest Botany—The Secretary, The University, Edinburgh (May 15).

Agricultural Economist (with a university degree in agricultural economics, agriculture, or economics, and practical experience in the organization of the export of horticultural produce, local marketing, and distribution problems) to act as Marketing Adviser to the Maltese Government—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/19/04.

Assistant Lecturer in Physics—The Registrar, The University, Nottingham.

Biochemist, Basic grade (with a science degree preferably with honours in biochemistry or chemistry)—The Secretary, Horton General Hospital, Banbury, Oxon.

Experimental Officer (with a degree in chemistry or agricultural chemistry or equivalent qualifications), to carry out chemical analyses of soils and plants—The Secretary, Rothamsted Experimental Station Harpenden, Herts.

Fisheries Officer (with a university degree in biology with emphasis on zoology, and experience of fisheries work) in the Northern Region of Nigeria, to execute plans for the development of river fisheries, and the demonstration and organization of peasant fish culture—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/408/01.

National Research Council of Canada Post-Doctoral Fellows in the Department of Chemistry—Dr. R. P. Graham, Chairman, Department of Chemistry, McMaster University, Hamilton, Canada.

Research Assistant (preferably graduate in chemistry, biochemistry or physiology) in the Department of Pathology, for work in connexion with steroid investigation—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, marking envelope "Research".

Research Officer (Soils) with a university degree in geology or natural science and at least two years postgraduate experience in tropical soils research) in the Forest Research Department, Federation of Nigeria, to initiate and carry out investigations and studies of forest soils—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.61/14/07.

CHEMISTRY of the STEROIDS

By C. W. SHOPPEE, D.Phil., D.Sc., F.R.S.
University of Sydney

This volume sets out to portray concisely the present state of knowledge of the chemistry of the steroids, the widely occurring group of natural products possessing the tetracyclic cyclopentenophenanthrene carbon skeleton.

The structural investigation of the sterols and the bile acids is accordingly given only in brief outline, but the later structural investigations dealing with the steroid hormones, the cardiac glycosides and aglycones, and the sapogenins are presented in full; steroid stereochemistry, partial syntheses, and total syntheses are also described in some detail.

An attempt has been made to cover the literature up to the end of 1955, and to include a few of the more important papers appearing in 1956.

Price 50s.

NATURALLY OCCURRING QUINONES

By R. H. THOMSON, D.Sc., Ph.D., F.R.I.C.
University of Aberdeen

This book presents, for the first time, a comprehensive account of the quinone pigments which form the largest group of natural colouring matters.

The quinones are considered mainly from a chemical stand-point with emphasis on their actions and constitution, and, with biologists in mind, the data on natural sources have been carefully compiled. The literature is completely covered up to the end of 1956, and there are many references to papers published in 1957.

Price 50s.

THREE DIMENSIONAL DYNAMICS

By C. E. EASTHOPE, M.Sc., Ph.D.
University College of Wales, Aberystwyth

This textbook is intended for second- and third-year students reading for a University Honours course. It will serve as a useful introduction to the vectorial study of the motion of a particle and of a rigid body when developed from first principles and when treated vectorially.

Since tensors are not so vital to the study of three dimensional dynamics as are vectors, they have been omitted; the theory of moments of inertia and that of Euler's equations are thus treated, in the main, by the traditional methods.

February, 1958. Price 42s.

MECHANICAL RESOLUTION of LINGUISTIC PROBLEMS

By A. D. BOOTH, D.Sc., L. BRANDWOOD, B.A., and J. P. CLEAVE, Ph.D., B.Sc.

The present book contains an account of some of the results which have been obtained by Dr. Booth and his colleagues at Birkbeck College Computational Laboratory on the application of digital calculators to linguistic problems. It is a record of the actual details of the translating techniques achieved with the APEXC computer.

No reference has been made to detailed programming, as a full account may be gained from the companion volume to this book, PROGRAMMING FOR AN AUTOMATIC DIGITAL CALCULATOR by K. H. V. Booth, scheduled for publication in March, 1958.

February, 1958. Price 50s.

LECTURES AND COURSES

MIDDLESEX COUNTY COUNCIL EDUCATION COMMITTEE

BRUNEL COLLEGE OF TECHNOLOGY
WOODLANDS AVENUE, ACTON, W.3
DEPARTMENT OF CHEMISTRY
(BIOLOGY DIVISION)

A short full-time course on "Food Microbiology" will be held in the Department during the week commencing Monday, March 3 to Friday, March 7, 1958. The course is designed for scientific staff engaged in the food industries who require some training and experience in the field of food microbiology. The course will include food poisoning and spoilage organisms; laboratory organization and method; use of statistical and mathematical methods; plant sanitation and the food hygiene regulations. Fee: £4.

Further particulars can be obtained from the Principal.

C. E. GURR, M.Sc., Ph.D.,
Secretary to the Education Committee.

UNIVERSITY OF BIRMINGHAM

POSTGRADUATE COURSE IN FOUNDRY SCIENCE AND ENGINEERING

A course of Postgraduate Training in Foundry Science and Engineering begins in the Department of Industrial Metallurgy on October 6, 1958, and will be completed in three terms. The course is open to men holding degrees or equivalent qualifications in metallurgy, physics, chemistry or engineering and it will lead to a Diploma or to a M.Sc. degree. The inclusive fee for the course is £81 and in suitable cases maintenance allowances may be given.

Full particulars may be obtained from the Registrar, The University, Birmingham, 15.

UNIVERSITY OF LONDON: A COURSE of three lectures on "Methods of Establishing Computer's Programmes in the Field of Business Administration and Statistics" will be delivered by Professor J. Engelfriet (Amsterdam) at 5 p.m. on February 14, 17, and 21 at the London School of Economics and Political Science, Houghton Street, Aldwych, W.C.2. Admission free, without ticket.—James Henderson, Academic Registrar.

UNIVERSITY OF LONDON: A COURSE of three lectures entitled "Physiological Mechanisms in the Protozoa"; (i) 'Somatic Regulation'; (ii) 'Cell and Environment'; (iii) 'Problems of Behaviour,' will be delivered by Dr. J. A. Kitching (Bristol) at 5.45 p.m. on February 17, 19 and 21 at Birkbeck College, Malet Street, W.C.1. Admission free, without ticket.—James Henderson, Academic Registrar.

OFFICIAL APPOINTMENTS

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF PHYSICS

Applications are invited for appointments as Lecturer, Assistant Professor, Postdoctorate Fellow and Research Assistant in the Department of Physics. The vacancies have been created by the rapid expansion of the university. They are mainly in the fields of nuclear physics, optical spectroscopy, solid state physics and geophysics. Applicants should have an honours degree in physics and, except in the case of Research Assistants, a Ph.D. degree. They should not be more than 30 years of age and should be available in September, 1958. There are also Teaching Assistantships available to help students who wish to pursue graduate work towards a Ph.D. degree.

Applicants wishing fuller information regarding any of these positions or awards should write to G. M. Shrum, Head, Department of Physics, University of British Columbia, Vancouver, B.C., Canada.

SCUNTHORPE HOSPITAL MANAGEMENT COMMITTEE

RADIATION MONITORING SERVICE

Vacancy for Technician or Technician in Training. Work mainly concerned with radiation measurement to ensure safe working conditions in X-ray and Therapy Departments of Lincolnshire Hospitals. Qualification for Technician in engineering or appropriate apprentice including experience in applied physics or design of instruments or O.N.C. in approved subjects, minimum age 21. Salary scales: Technician, £475 to £600; Trainee, £155 at age 16 rising to £380 at 25 or over. Whitley Council conditions of service.

Application form from Group Secretary, War Memorial Hospital, Scunthorpe.

UNIVERSITY OF CEYLON

Applications are invited for the Chairs of: Biochemistry, Agriculture, Mechanical Engineering, of the University of Ceylon. Preference will be given to experienced university teachers. The salary scale attached to the post of a Professor is Rs.15,000, rising by four annual increments of Rs.600 and four annual increments of Rs.900 to a maximum of Rs.21,000 per annum. The Council may appoint at any point on this scale according to qualifications and experience. Rent allowance (15 per cent of salary in the case of a married man and 7½ per cent of salary in the case of an unmarried man subject to a maximum of Rs.140 and Rs.70 per mensem, respectively) will be paid. First-class passage for the Professor, his wife, and not more than three children will be provided. The posts are not pensionable but the Professors will become contributors to the University Provident Fund contributing 5 per cent of salary and the University adding 10 per cent. The appointments will be for a period of four years in the first instance but may be renewed up to the age of 55 or 60.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in Ceylon and London, is March 1, 1958.

CARLETON UNIVERSITY

OTTAWA, CANADA
DEPARTMENT OF GEOLOGY

Vacancies exist at the Lecturer, Assistant Professor, and Associate Professor level in the following fields: Stratigraphy; Palaeontology; Sedimentation; Micropalaeontology; Sedimentary Petrology; Mineralogy (Advanced); Petroleum Geology. Duties: to institute courses at the honours and graduate levels. Qualifications: in addition to their particular specialization, candidates must possess a wide geological background and training. The minimum of a Commonwealth (or European) master's degree or an American Ph.D. is required. Salary scales (1957): Lecturer, $3,500 to $5,000; Assistant Professor, $5,000 to $7,000; Associate Professor, $7,000 to $9,000. (Salaries subject to revision.) Academic year: September to April.

Direct applications to Chairman, Department of Geology, Carleton University, Ottawa, Canada. Deadline for applications: February 28, 1958.

UNIVERSITY OF LEEDS

HOULDSWORTH SCHOOL OF APPLIED SCIENCE

Two temporary Research Assistants are required in the Ceramics Group of the Houldsworth School of Applied Science for a study of permeability of ceramics to gases at high temperature. The work will be mainly physics and physical chemistry and may lead to a higher degree. Salary within the range £400 to £750 according to age, qualifications and experience.

Applications should reach Professor A. L. Roberts, The University, Leeds, 2, not later than February 28.

UNIVERSITY OF TORONTO

DEPARTMENT OF PHYSICS
GEOPHYSICIST

Applications are invited from geophysicists (not over 35 years old) for appointment to the teaching staff of this Department. Duties to commence September 1, 1958. Salary and rank to be arranged according to qualifications and experience, and consistent with the University's salary scale. Applicants should have research interest and experience in some aspect of the physics of the Earth.

Write not later than March 1 to the undersigned, stating age, marital status, academic record and scientific career and naming two referees.

W. H. WATSON.
Professor and Head of the Dept. of Physics.

LOUGHBOROUGH TRAINING COLLEGE

Principal: J. W. Bridgeman, B.Sc.

Applications are invited for the following appointment, to date from September 1, 1958. Principal Lecturer in Anatomy and Physiology. Candidates should have high qualifications in physiology and preferably some experience as a university lecturer. This new post offers scope for research related to the teaching of physical education. Salary scale: £1,400 by £50 to £1,550 per annum.

Further details of this appointment may be obtained from the Principal, to whom applications should be sent on or before February 21.

UNIVERSITY OF CEYLON

Applications are invited for a Lectureship (Grade II) in Electrical Engineering (Electrical Machinery) on the salary scale Rs.6,600 by Rs.360 to Rs.8,400 per annum. Appointment may b made at a suitable point on the scale according t qualifications and experience. Qualifications honours degree in engineering. Two years o training or experience specially devoted to th design of electrical machines. Four years' teaching experience in a university. Corporate men bership of an Institution of Engineers, researc publications. Conditions of service: the appoint ment will be for a period of four years in th first instance but may be extended at the discre tion of the University Council. The post is no pensionable but the holder will become a contri butor to the University Provident Fund contributing 5 per cent of salary and the Universit adding 10 per cent.

Further particulars and information as to th method of application may be obtained from th Secretary, Association of Universities of th British Commonwealth, 36 Gordon Square, Lon don, W.C.1. The closing date for the receipt o applications, in Ceylon and London, is March 1 1958.

UNIVERSITY OF CAMBRIDGE

I.C.I. FELLOWSHIPS

Applications are invited for Imperial Chemic Industries Fellowships, value under review but a present within the range £600 to £900 a yea tenable in the University and available for re search in Physics, Chemistry, Colloid Science, Biochemistry, Engineering, Metallurgy, Pharmacology, Chemotherapy, or related subjects. Applications must be received not later than April 30, 1958.

Regulations governing the award of the Fellowships may be obtained from the Secretary General of the Faculties, The Old Schools, Cambridge, to whom all applications should be addressed.

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

ST. JOHN'S, NEWFOUNDLAND, CANADA

Applications are invited for the position of Pro fessor and Head of Department in Geology, o the scale $6,800 by $100 to $8,400, to take effe at September 1, 1958. Assistance towards tran fer expenses is contributed by the University.

Applications (in duplicate), with complete curr culum vitae and the names and addresses of thr referees, should be sent to the Secretary, Ass ciation of Universities of the British Commor wealth, 36 Gordon Square, London, W.C.1, b March 15, 1958. In addition, candidates shoul send one complete copy of application to th President, Memorial University of Newfoundland St. John's, Newfoundland, Canada, to reach hi by the same date.

CARDIFF HOSPITAL MANAGEMENT COMMITTEE

Hospital Biochemist (Senior Grade) require for Group Laboratory, St. David's Hospital, Ca diff. N.H.S. salary and conditions.

Form of application from Group Secretary, 4 Cathedral Road, Cardiff.

TEACHING FELLOW APPOINTMENTS

Appointments at $2,400 for the academic yea are available in chemistry to qualified student proceeding to M.Sc. and Ph.D. degrees. Nin hours per week of undergraduate laboratory instruction are required.

Applications should be sent to Professor Harr E. Gunning, Chairman, Dept. of Chemistry, University of Alberta, Edmonton, Alberta, Canada

---

PLYMOUTH, S. DEVON, AND E. CORNWALL GENERAL HOSPITALS MANAGEMENT COMMITTEE
AREA PATHOLOGY LABORATORY

Applications are invited from suitably qualifie persons for the post of non-medical Biochemis basic grade, in this Laboratory, at the Greenbar Road Hospital, Plymouth.

Applications, stating age, nationality, qualific tions, and experience, with names and address of three referees, to be sent to the Group Sec tary, 7 Nelson Gardens, Stoke, Plymouth.

HORTON GENERAL HOSPITAL, BA bury, Oxon. Applications are invited for the pointment of a Biochemist (Basic Grade) vac on April 1. Candidates should possess a scie degree preferably with honours in biochemis or chemistry.—Apply, with names of two refere to the Secretary.

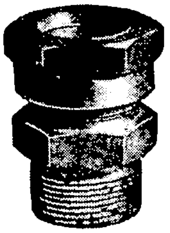
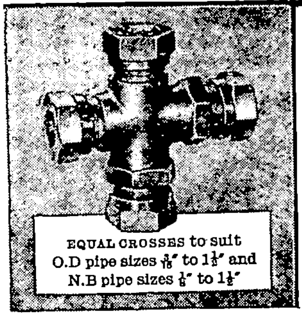
The international pipe couplings of proved efficiency

ERMETO high pressure couplings have several outstanding qualities, not the least of which is their trouble-free service even in conditions of extreme vibration. Beyond the removal of burrs no work is necessary on the pipe ends. Joints are made in a matter of moments and when required can be broken and re-made any number of times without impairing the pressure tightness.
Because of our specialized knowledge we have created a range of fittings to suit almost every conceivable purpose, but we are always prepared to supply fittings to suit individual requirements.
Literature and catalogues gladly sent on request.



PARALLEL MALE STUD COUPLINGS to suit N.B pipe sizes ⅛" to 1½"



EQUAL CROSSES to suit O.D pipe sizes 3/16" to 1½" and N.B pipe sizes ⅛" to 1½"

a new microscope for the assessment of surface finish

The Baker Surface Finish Microscope enables the surface under examination to be seen magnified in *three* dimensions : the normal linear magnification of a microscope *plus* the heights and depths of surface contour mapped out by the interference fringes to an accuracy of one micro-inch.

The microscope is equally suitable for examining metallic and non-metallic surfaces of high finish.

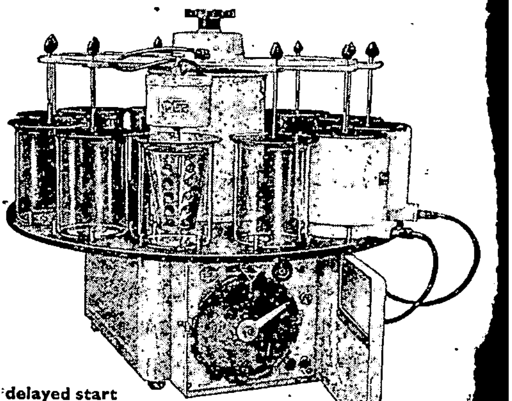
The *Histokinette* stays on the job



Diagnostic reports to hand hours earlier than they would be with manual processing and in far greater numbers—the release of a valuable technician for other duties . . . these are the outstanding advantages of the Histokinette Automatic Tissue Processing machine. Once the Histokinette has been put into operation, it will *without supervision* go through the entire cycle of fixation, dehydration, impregnation in wax, or alternatively can be set up for the washing or staining of tissues. It can handle large numbers of specimens at the same time and while staff is off duty—speed up almost any technique by ensuring quicker and more thorough penetration by reagents.

A 24-hour clock is fitted as standard. Change over to 1 hour or 7 day cycles (*the latter of great value in double embedding and bone decalcification techniques*) is simple and rapid.

Histokinette special features include:—

- Up to 24 hours delayed start
- Double processing capacity
- One or more motor members and baskets
- Unbreakable tissue basket and container

The Hendrey Histokinette is in general use at home and overseas

Two new cine-films for user processing

... are now available for laboratory photographers. One is extremely fast, with moderate grain; the other is a high-resolution film with very fine grain. Both provide exceptional image sharpness.

16mm Cine-Kodak 'Tri-X' Negative Film (36°...320 to daylight: 35°...250 to tungsten) is particularly useful for high-speed work. This film is available with normal 16mm perforations and also, to special order, with double-8mm perforations for use in certain high-speed cine-cameras.

16mm Cine-Kodak 'Plus-X' Negative Film (30°...80 to daylight: 29°...64 to tungsten) is a fine-grain high-resolution film, and is the best all-round material for laboratory use.

Please send for leaflet and Data Sheets giving full details.

These negative films are sold at a price which does not include processing. Users may either process films themselves or send them to a trade laboratory. A list of such laboratories will be sent on request.

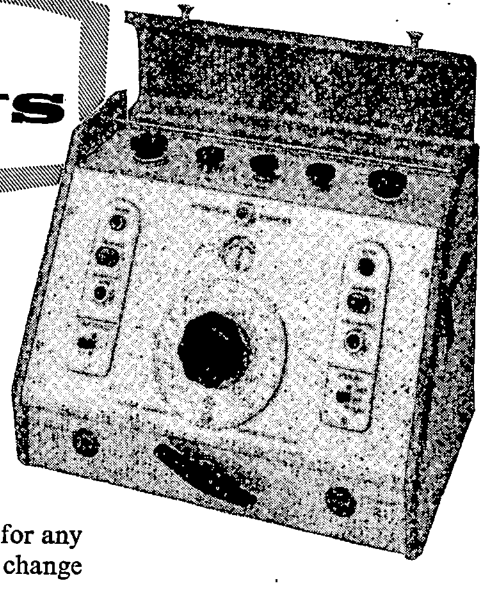
AUTOMATIC TITRATIONS



ARE easily carried out by the E.I.L. Automatic Titrimeter, Model 24. This instrument is fully automatic, switching itself off on reaching the pre-set end point.

Either the volumetric or the coulometric method may be used, and separate titration units for each type are available. Duplicated connections are provided on the Control unit.

The endpoint setting dial is calibrated in pH and in millivolts, and the equipment can be used for any type of chemical reaction producing a determinate change of e.m.f. The accuracy of titration is 0.05 c.c. in 50 c.c.

MAN-POWER IN THE ATOMIC ENERGY AUTHORITY

IN its first annual report, published in October 1955, the Atomic Energy Authority discussed its difficulty in recruiting sufficient staff, particularly senior staff and the younger engineers and technicians needed to form the base of the pyramid to-day and to provide the leaders in years to come; it also recognized that inadequacy of staff is a constant threat to achievement of the Authority's programme and admitted frankly that, even if dates continued to be achieved, details might be skimped which would cause operating troubles in future. That report was written in the context of the nuclear power programme outlined in the White Paper of February 1955. Since then, as Lord Mills announced in February of last year, the programme has been further expanded to provide almost treble the capacity of nuclear power; and although it is not expected that the number of nuclear power stations originally contemplated will be increased, the demands made upon scientific and technical man-power for such accelerated development as well as for operating will be appreciably greater.

It is therefore scarcely surprising that the Committee set up by the Prime Minister, under Sir Alexander Fleck's chairmanship, to examine the organization of certain parts of the United Kingdom Atomic Energy Authority should conclude that the continuous pressure on the Authority's Industrial Group to take on new tasks has strained its resources to the utmost, and left those responsible for operating factories within the Group with insufficient technical staff and inadequate technical assistance*. The many and varied commitments of the Group are fully recognized and also its remarkable success in bearing the tremendous load piled upon it. None the less, there are limits to what can be achieved with limited man-power, and the Fleck Committee is clear that the weaknesses in the Group's present organization arise primarily and noticeably from an insufficiency of senior technical staff in the Operations Branch. The Committee was impressed by the speed and success with which the Industrial Group has been built up; but the Group's ever-widening commitments have left it considerably under-manned, particularly in the more senior posts. In consequence, those in charge of operating existing plant have had inadequate technical assistance and advice, while liaison between the various branches of the Group and with the Research and the Weapons Groups at Harwell and Aldermaston is poor. Such factors as these were emphasized by the Windscale accident, which led to the appointment of the Committee, as was recognized at the time by the chairman of the Authority, and the Committee rightly considers it is essential to remedy them.

The recommendations of the Committee in this connexion have implications which extend far beyond the activities of the Atomic Energy Authority itself; but before considering them, the Committee's full terms of reference should be noted. It was first to review the organization and staffing of the Operations Branch of the Industrial Group of the Atomic Energy Authority and to make any recommendations necessary to ensure that the Branch is able adequately to discharge its responsibilities. It was to review similarly the staff engaged on the operation of reactors in the Authority's Research Group. It was to review the relation of the Operations Branch to the other branches and directorates of the Industrial Group and to the technical advisers in the Research Group, and to make any recommendations necessary to ensure that this relation is the one that best enables the Operations Branch to fulfil its functions, and that the division of responsibility between these various parts of the Authority is clearly defined. The relation of the staff engaged on the operation of reactors in the Research Group to other parts of organization was to be reviewed similarly.

The report begins by outlining general principles which the Committee considers should guide the organization of a large technological production group and then reviews the development of the Industrial Group and its present organization. On this basis are formulated the proposals for the reorganization of the Industrial Group Headquarters and for the reorganization at the works, and recommendations regarding the duties of the technical sections of the Operations Branch, the operation of reactors in the Research Group, and the special problems of Dounreay. Although in these latter respects the report enters into more detail than that of the Advisory Committee on the Organization of the Coal Board, it can fairly be placed with that report as an outstanding paper on administrative management, as well as one of profound importance for the efficient and economic use of scientific and technical man-power in general.

The Committee summarizes the present position in the Operations Branch by suggesting that the Branch has become seriously out of balance with the Engineering and the Research and Development Branches, and it insists that nothing should interfere with the provision of adequate staff, both for the safe and efficient operation of existing plant, and the development of completely safe and efficient plant for the nuclear power programme. These are the primary tasks of the Industrial Group, and the Committee points out that to ensure that the first stations for the nuclear power programme are designed and operated with the maximum efficiency and safety requires that those responsible for design, construction and subsequent operation have the benefit of full advice from the whole of the Authority, as well as full information based on the experience gained by the Industrial Group in operating its own reactors. The advancement of new techniques, while of high national importance, is secondary to this; and the Committee considers that should it become necessary to concentrate the Authority's development effort on fewer projects; this must be accepted as an inevitable consequence of the national shortage of suitably qualified technical staff.

---

* Report of the Committee appointed by the Prime Minister to examine the Organization of certain parts of the United Kingdom Atomic Energy Authority. Pp. 40. (Cmnd. 338.) (London: H.M. Stationery Office, 1957.) 2*s*. net.

The Committee is clearly right in this view; but before considering its various implications, the recommendations may be briefly noted. First, as regards the headquarters of the Industrial Group, no major change in the organization of the Group is recommended; after stressing the paramount importance of the two major tasks already indicated, the Committee emphasizes the importance of the principle of collective responsibility of board members and the vital role of the personnel branch in advanced technological work of the character on which the Group is engaged. A sound policy of recruitment, training and promotion of technical staff is so important that the director of personnel should be recognized as holding a key position in the organization, and in particular he should be responsible for ensuring that the available technical staff are distributed so as to ensure the proper functioning of the Group as a whole. It is also suggested that it should be his duty to press within the Authority for an active policy on staff recruitment, training and the interchange of staff.

The changes recommended with such conditions in mind are designed to give more time to think. Appointment of two deputy managing directors to assist the managing director, and, like him, substantially free from routine duties, is the first recommendation. Next, the board of management should include a director, appointed for a limited period and chosen for his scientific ability, specifically responsible for ensuring liaison with other Groups and appropriate external bodies, as well as a few visiting members from other Groups. In the detailed proposals for re-organizing the headquarters of the Operations Branch, stress is laid upon the importance of the senior posts being occupied by men of proved technical ability, while the need to strengthen the Administration Branch, which should be renamed Personnel and Administration Branch and its status enhanced, is also recognized. A new director, with a seat on the Board, should be appointed to take charge of the Dounreay site, while a review of the committee's structure relating to Industrial Group operations is also recommended.

The responsibilities of the director of the new Health and Safety Branch will be discussed fully in the report of the Health and Safety Committee, the third of the three Committees appointed by the Prime Minister following the Windscale accident; they are briefly summarized in this report as providing supervisory services both to the health and safety organizations at the works and to the Engineering and Research Development Branches in the design of all new plant and installations. At the works level, the Committee recommends that the existing practice of appointing works general managers to the major establishments, supported by works managers responsible for individual plants, should be continued. In particular, a separate works general manager, responsible direct to headquarters, should be appointed for Chapelcross. Emphasis is again laid on the importance of clearly laying down the chain of command at the works, and of encouraging interchange of staff between the Operations Branch and the Engineering and Research and Development Branches and the other Groups of the Authority; and it is pointed out that a works general manager should himself be a good technologist, and that the number of scientists and technologists available to him should be substantially increased.

The organization at the Research Group responsible for the operation of reactors is regarded as correct in principle and adequate for the present purposes; but it will require constant review as the complexities of the reactors operated by the Group increases. Besides the creation of a new post of director of Dounreay, as already noted, the Committee recommends that the functioning of this site should be reviewed in two or three years time, and it suggests that this experience may be of great value when the Winfrith Heath organization is being considered. Further, it suggests that the Authority should carefully review the time-scale and staffing problems of the Dounreay project in the light of its other commitments, and it points out that the very high fuel ratings of the fast reactor and the nature of the other facilities at Dounreay call for exceptional technical competence in its management.

These proposals involve the creation of numerous new senior technical posts, and although the filling of such posts is a matter for the Authority and not for the Committee, the latter recognizes that some of the posts can only be filled by transfer, and that time will be required to make such transfers and the related adjustments. None the less, it is emphatic that the posts must be created and filled, even if this necessitates some curtailment of the work at present being done. Nothing must interfere with the provision of adequate staff, both for the safe and efficient operation of existing plant and the development of completely safe and efficient plant for the nuclear power programme.

It is obvious that the Fleck Committee is not optimistic about the prospect of the Authority recruiting in the near future the substantial number of highly qualified men it requires to fill these new senior posts and to strengthen the technical staff of the Operations Branch at a lower level. It is possible that the Fleck Committee is too optimistic as to the possibility—or practicability—of finding the men from within the organization. Personal qualities and preferences can be a decisive factor in determining the choice of a post by a scientist or technologist, quite as much as ability; and it should not be assumed too readily that those who find satisfaction in research and advanced development at Harwell or Risley will necessarily be attracted to running a production plant. There are, moreover, the actual conditions to be considered: isolation itself will be a deterring factor to those keen on technical progress or creative work, unless a good deal of care is taken to offset such disadvantages as are inherent in sites like Dounreay.

The Fleck Committee does not doubt that, given the right leadership, the business of plant operation can be made attractive to highly qualified men, and it suggests that such posts may well become a good recruiting ground for men with both technical background and ability and some experience in management. None the less, it is fully alive to the plain truth that, on the whole, industry pays its men better; and that the Government decision that salaries of senior staff should not be seriously out of scale with those paid by public corporations, and the inheritance of a Civil Service grading structure, may continue to hinder both the recruitment from within established industry of sufficient senior staff and the grading of scientific and technical staff so as to cause the minimum obstacles to movement. The present difficulties will scarcely be settled so easily, and they demonstrate once more the relation of the whole problem to an adequate supply of scientific and technical man-power, to the esteem and status accorded to the technologist and to the far-reaching effects of a really adequate system of selection and training for the highest managerial positions.

Very clearly, although the problems lay outside the survey of the Fleck Committee, the Atomic Energy Authority cannot leave the matter there. It must reconsider its whole organization from the level of the main Board downwards. Only in the light of decisions as to the extent of its ever-growing responsibilities and what responsibilities in the long run can be transferred to industry or to other public bodies is a clear idea possible as to the magnitude and balance of the staff it needs.

The greatest importance of the report may well lie, however, in the wider implications that arise in this connexion. First, it is a convincing demonstration of the dependence of Britain's economic and industrial development upon the condition of scientific and technological education. It is our neglect to attend to this that is responsible for the present handicap under which the Atomic Energy Authority labours and which may cause us to miss some of the opportunities now opening to us.

Secondly, such weaknesses in education cannot be remedied quickly, but require the study and imaginative pursuit of a long-term policy, not only in educational circles but also in industry. Moreover, the report indicates once more that such a policy is unlikely to be formulated and implemented in industry, or for that matter in Government circles, unless there are men at the board and other high administrative levels who have themselves scientific and technical experience as well as vision and sound judgment. Such men are unlikely to be found in these positions except as a result of deliberate policy involving the careful search for talent and its selection, testing and training from early years. The extent to which the Government and industry in general ponder and apply the lessons to be learnt from this report, and bring a new understanding and urgency to the expansion of technological education, and to the selection and training of managers and administrators, will determine the speed with which the present difficulties of trained man-power which hinder the progress of Britain's nuclear power programme will be relieved—either by an increased intake at lower levels from the universities or colleges of technology, or at more senior levels from elsewhere in industry.

The key factor is management, for the best hope of providing the conditions most likely to attract the highly skilled scientists and technologists and to encourage them to give of their best depends on wise, resourceful and imaginative management. It is such management again that will minimize the shortage by seeing that such skilled man-power is adequately supported by technicians, craftsmen and clerical assistance, and that it is not wasted on tasks that could be done as efficiently or even better by less highly trained workers. It will be alert to eliminate misunderstandings and to check any tendency to disparage a post and so deter people from filling it; and in this matter of status, management will need, and should receive, the full support of all those who appreciate the nature and worth of the work of the scientist, the technologist and the technician in industry. The Fleck report could provide an admirable text for lecturers in the new programme of activities which the British Association has announced.

BREWING

A Textbook of Brewing

Vol. 1. By Prof. Jean de Clerck. Translated by Kathleen Barton-Wright. Pp. xx+587. (London: Chapman and Hall, Ltd., 1957.) 84*s*. net.

Of the two volumes which this translation will comprise, the present one is concerned primarily with the various sections of the brewing process, including malting, and with commercial equipment for that purpose, but it rightly incorporates considerable discussion and numerous references to relevant topics in pure science. A reviewer soon becomes keenly aware, as he reads this book, of the wide scholarship and great achievement of the author when in 1948 in the original French edition he brought together so many diverse facts and opinions from the different worlds of science and commercial brewing. In the present instance, a reviewer must indeed attempt to see the outcome from at least four points of view; in short he must regard the book as a text-book of brewing, as a contribution to science, as a translation and lastly as an attempt on the part of the translator to bring the original text up to date.

Clearly it would not be reasonable to expect this to be a text-book of brewing in the sense that it might take the place of practical experience. The object of the author has rather been to add to a general account of brewing practice a discussion of various modifications adopted in the major beer-producing countries of the world, and indeed the comparative differences encountered in malting and brewing procedure form a valuable feature of the book. The emphasis is, perhaps naturally, on Continental practice, and, although British and American usage is not forgotten, the unwary reader could sometimes be misled. For example, even remembering the possible injustice of quoting isolated statements, the assertion that in Great Britain certain types of wood are used as fuel in kilning malt so that the smoke may impart a special flavour is literally true but is scarcely a fair summary of British methods. As a translation the English version of the brewing sections is in every way excellent; practically no indications remain of the original having been in French. Valuable efforts have been made to bring the technical aspects up to date. In particular the section on malting is notable because of the paucity of modern texts on this topic, while other chapters like those on filtration and bottling will also be generally welcomed. Perhaps some readers will expect a rather less superficial and descriptive approach or will be disappointed that certain aspects, such as the formation of haze in beer and the related topics of the amount of air included with bottled beer, have not received the detailed critical appraisal which they would often seem to demand.

Turning to scientific content, the account is primarily factual and, probably unavoidably, gives much weight to empirical rules which are sometimes based on little or no scientific evidence. For example, hand evaluation of barley is said to lead only rarely to mistakes, but obviously this can be justified only by experience of those relatively few varieties which have been under long observation, and it does not necessarily apply to new hybrids such as are now commonly grown and which have been developed for special characteristics. Again, the unwary reader could sometimes be misled, perhaps to some extent as a result of restriction of space. Thus on p. 60 an erroneous structure is given for colupulone, it is wrongly stated that humulone and lupulone are derivatives of quinone, while in some respects the discussion of hard and soft resins of hops is scarcely consonant with modern thought on this topic. It must be added that these considerations mostly arise in connexion with recent advances in rapidly moving subjects, and that they arise at all must be set against the fact that recent work on the science of brewing, especially since the Second World War, has been more exhaustively covered than technical advances over the same period. These are, in any event, only minor deficiencies, for the main object of the book is not to turn the scientist into a brewer but to explain to the latter something of the scientific basis of his craft so that technical improvements can be devised more surely than by guesswork alone. If that basis were to concern one department of science alone, the task would have been formidable enough. Actually it involves many quite widely separated sciences such as agronomy, structural organic chemistry, colloid chemistry and the genetics of micro-organisms, to mention only a few. It is the more remarkable, therefore, that the author and translator have jointly succeeded in producing the most comprehensive international work of its kind to have appeared for a long time.

A. H. COOK

DEMOGRAPHY OF AN UNDER-DEVELOPED TERRITORY

The Population of Jamaica

By George W. Roberts. Pp. xxii+356. (Cambridge: At the University Press, 1957. Published for the Conservation Foundation.) 40*s*. net.

A NOTABLE feature of the progress of demography in recent years has been the increasing attention paid to the under-developed—that is, poor and relatively non-industrial—territories. Typically, these have a high birth-rate and a mortality which is decreasing owing to famine control and improved hygiene and medical services. As a consequence, there is steady, and often rapid, population growth which is a major factor in any attempts to raise living standards. Only a few full-length studies of such areas have appeared, and this account of the demographic history of Jamaica is an important addition to their number. It was written as part of a research project sponsored by the Conservation Foundation, an American organization formed to promote knowledge of the Earth's resources, and is the first of three reports on Jamaica's population problems. The others are to be about a field study of family relationships and attitudes as they affect reproduction and the use of land and resources, respectively.

In some ways Jamaica is a particularly useful choice for such a study. The population of one and a half million is sufficiently homogeneous for the overall demographic characteristics to have meaning. A further advantage is the existence of fairly early records. In addition, the main trends are of almost text-book form. Fertility has been stable and fairly high over a long period but is now declining, while mortality has fallen steeply since about 1920; the rapid population growth is associated with serious unemployment. Mr. Roberts has made a very thorough study of the demography of the island from the early eighteenth century to the present day. Most of the data on which the account is based come from censuses (held since 1844) and birth and death registration, but other records, particularly for the earlier periods, are used skilfully, including those relating to importations of slaves and indentured labour. The nine chapters of the book are divided in the following way. After an opening chapter on the demographic material there are one each on the growth of population and its major characteristics, two on migration, one on mortality and two covering the inter-linked subjects of fertility, mating and reproduction. The final chapter gives some projections of the population up to 1971. Throughout, considerable attention is paid to details for regions, as well as for the island as a whole, particularly in relation to urban development.

Data for studies of this kind are always faulty and incomplete and one of the main criteria of their merits is how these difficulties have been handled. The book is very strong here. Wherever possible, the accuracy of records is cross-checked and a number of ingenious methods of analysis are applied. Interesting use is made of the survivorship table approach to illuminate problems. Mr. Roberts's judgment is always sound, but in a few places his close knowledge of Jamaican conditions leads him to tentative explanations which are not too convincing since they are a product of personal experience rather than of the evidence presented. He never, however, confuses speculation with reasoned conclusion. The discussions and presentation are clear, but some of the descriptions of analysis techniques are too cursory, and careful reading is needed to determine exactly how they were applied and the assumptions made.

The records for Jamaica have the great advantage of fair accuracy but, in many respects, they are very limited. In particular, there is little break-down of the number of births and child deaths by the characteristics of the parents. Thus no close study of differentials in fertility and mortality—the most satisfactory approach in the search for causes—is possible. This is a serious restriction, notably in connexion with the complex pattern of mating which involves 'keeper' unions and consensual and legal marriages; here differentials can only be guessed at by indirect means. It seems possible, then, that the weaknesses of the basic material will greatly reduce in scope the studies of further aspects of Jamaican demography. Some small-scale sample surveys of the mating and reproductive histories of women would surely give results of enormous value in this area.

W. Brass

A BROAD VIEW OF ECOLOGY

Agricultural Ecology

By Prof. Girolamo Azzi. Pp. xv+424. (London: Constable and Co., Ltd., 1956.) 45*s*.

The ecology of agricultural crops is a subject which is well worked and yet little known. There is a mass of undigested information about an enormous range of crops. In fact, much more is available than for wild plants, which are the plants with which ecologists usually deal. For this reason, a new book is very welcome, especially so since it is written by someone who has been intimately connected with the subject for thirty-five years.

With such a wide field it would be possible to write a safe, factual, rather prosaic book. However, Prof. Azzi has preferred to write differently. "Agricultural Ecology" is a book of imaginative ideas, around which is woven a considerable amount of information, most of which has not been available in English before. While to some Prof. Azzi's treatment may be annoying, it is both stimulating and provoking, and sorts out some of the tangle of factors affecting the growth of plants in the field.

The author begins with climate. Looking at it from the point of view of the plant, he shows very clearly the division of the growth of plants into periods. As the plant passes from one period to another, so its climatic needs—cold, heat, water, etc.—vary. In each period a different factor is critical and may be limiting to growth and final yield. A mass of data is given for a considerable variety of crops, both tropical and temperate, and it includes critical estimates of crop needs in each period. Of particular interest are the figures for rainfall need and the passing references to the critical factors concerned in such things as different as wheat rust and cotton boll weevil.

With the help of the critical factor concept, the normal maps of climatic factors are converted into maps of crop physiographic zones, and polygon figures combining factors together are used for representing crop climatic ranges diagrammatically.

Soil is treated in the same cavalier but provoking fashion. Soils are classified on the basis of an index derived from chemical content, water balance and workability, and not on a more classical pedological basis. As a result, it is possible to correlate productivity with soil characteristics.

The last part of the book is concerned with the yield of the plant as such, and its relation to specific ecological factors. Quality is linked to quantity, and seed quality and the effects of vernalization are not forgotten. Out of it all Prof. Azzi develops a general concept of the inter-relations of velocity of growth, size and structure of crop plants, and again he is able to relate it to productivity.

Here then is a curious book, both delightful and infuriating. The publishers say that it is the definitive text-book in agricultural ecology. I cannot agree with them. In one romantic sweep, Prof. Azzi has turned inside out every conceivable aspect of the growth of plants. He has thrown on one side almost every traditional approach, omits almost completely references to work published in English, and makes no use of statistics. Many will think his ideas are not so proper as classical ones. Yet perhaps they are nearer to fundamentals. It is remarkable but true that we still know very little about crop yields and that most of us are content to accept variations in yield as we find them or to explain them piecemeal in terms of individual factors. Prof. Azzi is not. Perhaps his book will stimulate others to enter this field and to continue his good work.

A. D. Bradshaw

WOMEN GRADUATES

Wives Who Went to College

By Judith Hubback. Pp. viii+164. (London: William Heinemann, Ltd., 1957.) 12*s*. 6*d*. net.

Women who have had a university education want to use their capacities to the full and to make a contribution to society. How can they combine this with marriage and motherhood? Mrs. Judith Hubback, herself a graduate mother, tried to find this out by sending out, in 1953, a questionnaire to 2,000 married women graduates (of whom 58 per cent replied) asking about their types of training, marital status, domestic and social circumstances, number of children, incomes, professional careers and their state of overtiredness or satisfaction. She wanted facts to refute prejudice and to establish whether these women were actually mis-employed, what types of part-time work they followed and what form of education really intelligent girls should be given. As a control, 420 non-graduate wives with a similar social background were asked the same questions.

The first account of this research, financed partly by the Leche Charity, appeared as a Political and Economic Planning broadsheet entitled "Graduate Wives". The present book analyses the answers and discusses the issues raised. It is found that the marriage-rate for women graduates is almost up to the normal, that they tend to be more fertile than average, that it takes some fifteen years before the last child is at school, that circumstances during the period of raising children give little opportunity for systematic intellectual pursuits or for an outside career, but that part-time teaching is the career most easily combined with family life, although many other paid or voluntary occupations are followed by some of the sample. At the time of the survey 64 per cent are at home full-time, but a large proportion of the graduates intend to follow a career later, in contrast to the control group. A whole chapter is devoted to overtiredness, due to diffuse, routine domestic work, which leads to frustration, and it is found that work outside the home, even part-time, results in a freshness of outlook and not in extra fatigue.

In the discussion, the need is stressed for a sane compromise between the biological aspects of a woman's life, as a mother carrying on the race, and the intellectual side developed by a university education.

It is suggested that modern emphasis should be on the diversity, rather than the identity of the sexes, and that a girl's education should enable her to evolve from the exclusive femaleness of the family stage, where, however, intelligence is not wasted, to the fulfilment of a wider personality later in life, given sufficient stamina, patience and a sense of proportion.

Practical issues are dealt with, and it is shown that the effect of the change in the balance of the population from a surplus of women to a surplus of men with the present early marriage-rate will lead within the next twenty years to a shortage of unmarried women of professional status, so that it will be more and more necessary to adapt conditions to the employment of married women. One essential change will be in the system of assessing income-tax paid by a married woman.

By collecting actual facts, Mrs. Hubback has done valuable work in raising this subject one step above the surmise and prejudice usually associated with it. From the trends observed, although the sample is small and not claimed to be statistically perfect, she draws valuable information leading to the conclusion that, while admitting the educational dilemma due to her probably dual role in life, an intelligent girl should be educated to the highest level of which she, as an individual, is capable and that she should continue her education to qualify for professional status. Because the author herself and the majority of her sample are at the family-raising stage she puts, perhaps, too low a value on the potentialities of highly educated women. It would be interesting and possibly more encouraging to career-minded girl students to have a further survey of the careers followed at the next stage, later in life, when so many professionally trained married women are tending to return to outside work. C. E. Arregger

THE SCIENCE OF COSMETICS

Cosmetics

Science and Technology. Edited by Edward Sagarin. Pp. xix+1433. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1957.) 25 dollars.

The avowed intention of the editors of this volume is "to bring together a number of authorities each of whom has acquired a thorough familiarity with some special phase of cosmetics or of some related science or technique". In this object they appear to have succeeded since sixty-one men and women have written fifty-three chapters covering the whole range of cosmetics.

This very large quantity of material is subdivided into five parts: 1, The Scope of Cosmetics; 2, Toilet Preparations; 3, Manufacture and Technology; 4, Physiological Considerations; 5, Legal Considerations.

Part 1 includes a chapter on the origin and development of cosmetic science from the days of the Egyptian and Babylonian Dynasties until the nineteenth century when the basis of modern cosmetic formulation begins to appear.

The major part of the book is to be found in Part 2. Fifty types of cosmetic preparations are grouped into thirty-five chapters, two or more allied preparations being incorporated together in some chapters. Each chapter is prefaced by a discussion of the requirements of the preparation to be compounded. This discussion involves a consideration of pharmacology, of presentation and of storage problems.

A lengthy chapter is included on aerosol cosmetics. This contains a discussion on the various types of propellants, the advantages and disadvantages of each, with numerous graphs showing the vapour pressures of various mixtures of these propellants. Types of containers and production methods are also considered. The chapter also includes a glossary of terms used in the aerosol industry—terms approved by the Chemical Specialities Manufacturers Association.

The numerous and varied formulæ are well set out in the text with the reasons for the inclusion or exclusion of any particular ingredient. Manufacturing instructions are given for nearly every formula, and where they are not included they can be deduced from similar formulæ.

Part 3 includes a very useful chapter on quality control emphasizing the necessity of statistical analysis. The subject of statistics is treated in as simple a manner as possible—formulæ are given but not proved. Consideration is given to the standard deviation, the Student *t* test, confidence limits, correlation and regression lines, analysis of variance. Useful information on the design of experiments is supplied.

Part 4 includes chapters on "The Physiology of Olfaction", "Hormones in Cosmetics" and "Sensitivity Testing". Part 5 includes a chapter on American patents and trade marks and a copy of the relevant parts of the Federal Food, Drug and Cosmetic Act, 1955.

The editing of the book has been extremely good, and little overlapping of information occurs in its many chapters. Each chapter is fully and widely referenced. The theoretical knowledge given, where it is required in each chapter, is generally good, although occasionally it is a little ambiguous when emulsions are being considered, but as the book is essentially one of cosmetic practice, these statements do not interfere with its usefulness.

The line diagrams are clear and well annotated; the graphs and tables self-explanatory. The photographs are good, although pictures of large-scale plant are not very enlightening. In the photographs of the mineral oil emulsions, two reference letters are missing.

An index of trade names is given, including details of chemical composition and manufacturers' names and addresses. The author index appears to be complete and is certainly well cross-referenced. The subject index is extensive, but, and this is probably the most serious fault with the book, it is not complete. Many substances are mentioned in several places in the text but only receive one reference in the index. Some substances are, unfortunately, mentioned in the text but not in the index.

These faults apart, the editors can congratulate themselves and the authors on producing a book which cannot help but be of great use to every cosmetic manufacturer (or would-be manufacturer) throughout the world. Cyril W. Ridout

l'Énergie Nucléaire dans le Monde

Programmes et Développements Prévus. Par T. Reis. Pp. x+296. (Paris: Dunod, 1957.) 2,900 francs.

THIS book provides a useful summary of the world's energy consumption and its distribution among available sources. It provides statistics of the energy consumption of most of the countries of the world and summarizes the predictions that have been made about the future growth of energy requirements.

The second chapter describes the atomic energy organizations of more than forty countries, lists their reactors of different types and gives their nuclear power programmes—where they exist. The information given is as accurate as could be expected when programmes change rapidly.

The third chapter summarizes the conclusion about the world's future requirements and predicts that in Western Europe nuclear energy will be providing between 15 and 20 per cent of all electricity generated by 1975. This would still only be 18 per cent of the indigenous energy deficit of the Organization for European Economic Co-operation countries.

A final table classes eight countries in order of nuclear power output by 1960, 1965 and 1970/75. According to this, Britain will take third place in 1960 and second place in later years, Canada being credited with second place in 1960. These predictions are of little value in the present shifting phase of national programmes. J. D. Cockcroft

Contributions to the Flora of Venezuela

By Julian A. Steyermark and Collaborators. (Fieldiana: Botany, Vol. 28, No. 4.) Pp. ii+512. (Chicago, Ill.: Chicago Natural History Museum, 1957.) 7.50 dollars.

THIS volume is the final instalment of new records, notes on range extensions, and descriptions of new species based on Dr. Steyermark's notable botanical collections on the mountains of Venezuela, especially on those of the Guayana Highlands, some of which had never before been explored by biologists. These contributions are of absorbing interest for the taxonomist and plant geographer, but the promise to include special notes on geology, topography, floral zones and ecological aspects in the sections devoted to certain mountains can scarcely be said to have been fulfilled. This final volume closes with a list, in taxonomic order, of all the new plants which have been described in the contributions. A complete set of Dr. Steyermark's specimens is placed in the Chicago Natural History Museum.

BBC Handbook, 1958

Pp. 288. (London: British Broadcasting Corporation, 1957.) 5*s*.

THE B.B.C. Handbook 1958 includes the balance sheet and accounts for the year ended March 31, 1957, as well as a brief analysis of income and expenditure for that year among the regions, an analysis of both sound and television programmes and a comparison of programme services costs. It also gives a comprehensive account of the Corporation's activities prior to the recent changes in the sound programmes. Following Sir Alexander Cadogan's foreword, a chapter on the constitution of the Corporation refers briefly to the 'fourteen-day rule' forbidding the anticipation of Parliamentary debates, but neither there nor elsewhere is there any discussion of live issues. The Handbook is essentially factual and descriptive: besides a review of the year's broadcasting, there are chapters on the domestic broadcasting services; the external services; the work and responsibilities of the engineering departments and their technical facilities and installations; programme policy and practice; and relations with the public, the latter including some advice on how to get the best reception. The texts of the Corporation's charter, licence and agreement and supplementary agreement are given, and the Handbook includes a useful select bibliography.

The Terpenes

By the late Sir John Simonsen and Dr. W. C. J. Ross. Vol. 4: The Triterpenes and their Derivatives: Hydrocarbons, Alcohols, Hydroxy-aldehydes, Ketones and Hydroxy-ketones. Pp. ix+524. (Cambridge: At the University Press, 1957.) 70*s*. net.

THIS is the fourth volume of a series, so it needs little in the way of general introduction. It contains accounts of the structures, degradations and general reactions of the compounds listed in the title, and some indication of stereochemistry. References are given up to 1956, but there are indications that some sections were substantially completed rather earlier than this, which is a disadvantage, although perhaps an inevitable one in a rapidly moving field. The volume is otherwise a very clear and complete account of the subject. The one quarrel which the reviewer has with it is the inadequate consideration given to stereochemistry. The results are stated in most cases, it is true, but without much account of the way they are derived. Conformations are not given. This is clearly a matter of deliberate policy, but the result is rather like raspberry jam without the seeds, wholesome and nourishing but a trifle unreal. It is a definite drawback to the use of the single volume. However, nobody who has the earlier volumes or who is interested in research or teaching in this field can afford to be without this book.

A. J. Birch

Kandelman's Krim

A Realistic Fantasy. By Prof. J. L. Synge. Pp. 175. (London: Jonathan Cape, Ltd., 1957.) 15*s*. net.

AN Orc, a Kea, a Unicorn and a Plumber, meeting to discuss the nature of infinity and the attributes of God, are joined by a sky-blue Goddess; her knowledge of arithmetic resembles Sam Weller's knowledge of London, but she does not understand why the debaters appear to be so interested in mathematics. Instruction is thrust upon her—integers, fractions, complex numbers, sequences, limits. Controversy is enlivened by flashes of wit and chunks of Carrollian nonsense.

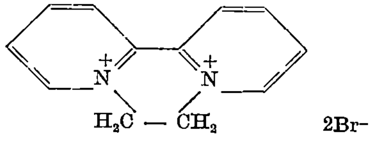
Temptation to see an allegory is strong. Surely the Plumber, with his strong constructive sense, his appreciation of mathematical techniques and his deprecation of formalism and academic subtlety, is the modern mathematical physicist, while the sceptical and pedantic Orc is the orthodox pure mathematician, roused only once or twice to a passion which suggests descent from the Orc of William Blake. But the allegory is obscure, and the long preface, with its discussion of meaningful and meaningless statements, its references to Berkeley and to the author's ancestor, Bishop Hugh Hamilton, may be a veiled warning against seeking a meaning where none exists. The fun is there to be enjoyed, and only the careless reader will miss the implication that real mathematics is as much the product of imagination as of logic. T. A. A. Broadbent

A NEW HERBICIDE

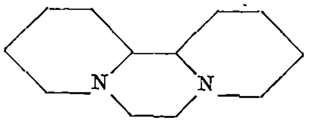
I : 1'-ETHYLENE-2 : 2'-DIPYRIDYLIUM DIBROMIDE

By R. C. BRIAN, R. F. HOMER and J. STUBBS
Imperial Chemical Industries, Ltd., Jealott's Hill Research Station, Bracknell, Berks
AND
R. L. JONES
Imperial Chemical Industries, Ltd., Pharmaceuticals Division, Alderley Park, Macclesfield, Cheshire

DURING the early spring of 1955, in the course of an investigation at Jealott's Hill Research Station into the herbicidal properties of a series of quaternary ammonium compounds, one chemical showed exceptional activity. This was originally prepared by R. J. Fielden at Blackley by the quaternization of 2 : 2'-dipyridyl with ethylene dibromide ; a reaction which gives rise to a single well-defined crystalline product which has been shown to be 1 : 1'-ethylene-2 : 2'-dipyridylium dibromide (*X*)[1].



(*X*)



(*Y*)

Elementary analysis agrees with the empirical formula $C_{12}H_{12}N_2Br_2$, in which all the bromine is ionic, and hydrogenation over Raney nickel in the presence of sodium acetate gives a fully saturated base $C_{12}H_{22}N_2$(*Y*), b.p. 74–76°/0·2 mm., which has molecular weight (cryoscopic in benzene) 186. $C_{12}H_{22}N_2$ requires 194. This eliminates possible dimeric or polymeric structures.

1 : 1'-Ethylene-2 : 2'-dipyridylium dibromide forms a pale yellow monohydrate from water m.p. > 320° decomp. having in aqueous solution $\lambda_{\text{max.}}$ 308,311 mμ ; $\varepsilon \sim 18{,}000$. The material is readily soluble to the extent of 70 gm. in 100 c.c. of water at 20° C. and is stable in acid or neutral solution. In alkaline solution coloured complex products are formed which appear to arise from the opening of one of the pyridine rings, a process associated with the uptake of one molecule of alkali.

In the greenhouse, aqueous solutions of *X* with added wetter (0·3 per cent 'Agral *LN*'), applied as foliage sprays at the rate of 100 gal./acre, gave complete kill of wheat, sugar beet, white mustard, marigold (*Calendula* sp.), red clover and cleavers (*Galium aparine*) at dosages down to ½ lb./acre. At ¼ lb./acre, there was 100 per cent kill of marigold, almost complete kill of mustard and serious damage to the remaining species. Even at ⅛ lb./acre, *X* seriously damaged all the plants other than cleavers. In the absence of wetter, the chemical was almost equally effective, though it was less damaging to wheat and clover. Similar results were obtained with low-volume (20 gal./acre) applications. The action of the chemical was very rapid.

From general observations on the effects of the treatment, and because the volume of application had so little effect on the activity, it seemed likely that *X* was acting systemically. Proof of the uptake and translocation through the aerial parts of broad bean and oat was readily obtained. Further, it was found that entry through intact bean leaves was very rapid, taking place within five minutes of application. Root uptake by oats growing in culture solution also occurred, though soil drenches had no effect on pot-grown plants. This apparent anomaly was explained when it was found that *X* was rapidly and completely adsorbed by soil.

Subsequent greenhouse tests showed that *X* was highly active against several common weeds at ¼–½ lb./acre, including the species resistant to 2,4-D and MCPA, chickweed (*Stellaria media*), groundsel (*Senecio vulgaris*), mayweed (*Matricaria* spp.) and speedwell (*Veronica* spp.). Russian thistle (*Salsola pestifer*), a common arable weed of North America, was highly susceptible, being killed at rates as low as ¼ lb./acre.

Because of its high activity in these initial tests, *X* was clearly worthy of further evaluation as a herbicide. Preliminary field trials confirmed that there was generally little difference between high-volume and low-volume application. For this reason, in most of the later trials the treatments were applied at 20 gal./acre.

Excellent potato haulm destruction was given by *X* at 1–2 lb./acre in a series of fourteen trials carried out in the period 1955–57, haulm kill being equal to that given by the standard sulphuric acid and sodium arsenite treatments and faster than the latter. Kill of common annual weeds, including fat hen (*Chenopodium album*), red shank (*Polygonum persicaria*), annual nettle (*Urtica urens*), chickweed (*Stellaria media*) and black nightshade (*Solanum nigrum*) by the new chemical at these rates was usually superior to that given by either sulphuric acid or sodium arsenite. Rain falling shortly after application had no effect on the herbicidal activity of *X* although it reduced that of the arsenite. The storage properties of the potato tubers were unaffected by the *X* treatments.

Indications that *X* was of value as a pre-harvest desiccant of red clover seed crops were obtained in a preliminary trial in 1956. This finding was confirmed in a more detailed trial later in that season and again in 1957, when it was shown that low-volume application of *X* at 1–2 lb./acre desiccated the crop at least as well as sulphuric acid (15 per cent B.O.V.) applied at 100 gal./acre.

Damage to cereals by X in the field was less than had been anticipated from the greenhouse observations. Oats proved to be the most resistant, and rates of up to 2 lb./acre mainly caused only localized foliar scorch. Wheat, maize and barley showed increasing damage in that order. Temporary chlorosis of the younger leaves sometimes developed, particularly with the more susceptible species. Grain yields in weed-free stands of spring oats and wheat in 1956 were not reduced following spray application at the 2–3 leaf stage of up to 1 lb./acre, but were affected by later treatments. Yields of spring barley were reduced in all cases; maize was not taken through to yield. In a series on weed-infested crops in the same season the treatments had no effect on yield in one trial on winter wheat and two on winter oats. Significant yield reductions, however, were recorded at two other centres where spring wheat and oats had been sprayed at later stages of development at 40 and 100 gal./acre, respectively.

Most species of broad-leaved annual weeds present in these cereal trials were adequately controlled by X at 1 lb./acre, exceptions being corn poppy (*Papaver rhoeas*), corn marigold (*Chrysanthemum segetum*) and parsley piert (*Aphanes arvensis*), which were markedly resistant. The activity shown by X in greenhouse tests against cleavers, chickweed, groundsel, mustard and speedwell was confirmed in these field trials. In addition, knotgrass (*Polygonum aviculare*), black bindweed (*P. convolvulus*), redshank (*P. persicaria*), charlock (*Sinapis arvensis*), runch (*Raphanus raphanistrum*), cut-leaved dead-nettle (*Lamium hybridum*), many-seeded goosefoot (*Chenopodium polyspermum*), fat hen (*C. album*), orache (*Atriplex* spp.) and scarlet pimpernel (*Anagallis arvensis*), all proved to be susceptible at rates of 1 lb./acre or less.

In these, and other trials, X gave good kill of top growth of several broadleaved perennial species, including dock (*Rumex* spp.), creeping thistle (*Cirsium arvense*), mint (*Mentha* spp.), field bindweed (*Convolvulus arvensis*), ox-tongue picris (*Picris hieracioides*) and ground elder (*Aegopodium podagraria*). Basal regeneration in these perennials, however, quickly nullified the effect of the treatment. Similar responses were given by a range of grass species.

Low-volume applications of X at 2–5 lb./acre gave good top kill of various brushwood species, including bramble (*Rubus* spp.), briar (*Rosa* spp.), hawthorn (*Crataegus monogyna*), elder (*Sambucus nigra*), elm (*Ulmus* spp.). In all cases, however, the initial dieback was followed by basal regeneration.

Clearly, 1 : 1′-ethylene-2 : 2′-dipyridylium dibromide is a very potent, translocatable, rapid-acting, non-persistent, post-emergence herbicide. Potential outlets seem to lie mainly in the field of potato haulm destruction, crop desiccation and non-selective weed-killing, though it may find some application as a selective weedkiller in cereals. More research is needed before the full potential of this new herbicide can be defined.

Considerable assistance with the field trials reported here was given by H. C. McIlvenny and L. G. Spencer.

NON-CONSERVATION OF PARITY

The situation in the field of elementary-particle decay interactions altered profoundly during 1957. With experiments demonstrating violation of parity in β-decay[1] and π–μ–e-decay[2] early in the year a new phase began in experimental work as well as in theoretical understanding of these weak interactions. A symposium, organized by Prof. R. E. Peierls, was held at the Royal Society on December 5 to assess the present situation in the field. The meeting was organized in two formal and one discussion session. An introductory talk by Prof. Peierls was followed by one from Dr. D. L. Pursey (Edinburgh), who gave a summary of β-decay and μ-decay theory. Dr. M. A. Grace (Oxford) surveyed the experimental situation in β-decay, and Prof. J. Cassels the situation in π–μ–e-decay. Drs. P. E. Cavanagh and E. C. Ridley described experimental techniques for measuring electron polarization and electron–neutrino correlation, and Prof. A. Salam (Royal College of Science, London) spoke on 'strange' particle decays. This article offers a brief discussion of some of the material presented.

The principle of space-reflexion symmetry asserts that there is no fundamental difference between right and left; that the results of any experiment look the same to an observer viewing the experiment directly as to one looking at its reflexion in a mirror. In elementary-particle physics this implies that transition probabilities for any reaction must not involve any pseudoscalar quantity. Pseudoscalar quantities are those which change sign on reflexion ($\mathbf{r} \rightarrow -\mathbf{r}$). Simple examples of these are products such as $\mathbf{p}_1 \wedge \mathbf{p}_2 \cdot \mathbf{p}_3$, where $\mathbf{p}_1$, $\mathbf{p}_2$, $\mathbf{p}_3$ are three (momentum) vectors, or $\mathbf{J} . \mathbf{p}$., where $\mathbf{J}$ is an angular-momentum vector. (It may be recalled that angular momenta behave similarly to $\mathbf{r} \wedge \mathbf{p}$ for reflexions. For $\mathbf{r} \rightarrow -\mathbf{r}$, $\mathbf{p} \rightarrow -\mathbf{p}$, $\mathbf{J} \rightarrow \mathbf{J}$ and thus both $\mathbf{p}_1 \wedge \mathbf{p}_2 \cdot \mathbf{p}_3$ and $\mathbf{J} . \mathbf{p}$ change sign.)

The principle of space-reflexion symmetry is known to hold in classical physics as well as in atomic and nuclear physics to all measurable accuracy. Yang and Lee[3] were the first to point out, in the summer of 1956, that no experimental confirmation had been obtained whether pseudoscalar quantities do in fact occur in expressions for transition-rates of decay processes. The first experiments performed with polarized neutrons[1] and μ-mesons[2] showed unmistakably that these rates are proportional to $a + b <\mathbf{J}> . \mathbf{p}_e$, where $<\mathbf{J}>$ is the vector representing neutron or μ-meson spin and $\mathbf{p}_e$ is the momentum of the electron emitted. These experiments also showed one other characteristic which has proved extremely valuable for their theoretical interpretation. This was the observation that in all neutron (n) decays the emitted electrons spin in the opposite sense to their direction of motion[4] (left-polarization) with a polarization of magnitude v/c, while in the inverse transitions and in μ^+-decay[5] the emitted positron possesses right-polarization of the same magnitude.

All decays can be classified into two categories:

Category (1). Decays involving neutrinos (ν) as one of the decay products: (1) $\mu^\pm \rightarrow e^\pm + 2\nu$; (2) $n \rightarrow p + e^- + \nu$; (3) $\pi^\pm \rightarrow \mu^\pm + \nu$; (4) (*a*) $K^\pm \rightarrow \mu^\pm + \nu$; (*b*) $K^\pm \rightarrow \mu^\pm + \nu + \pi^0$; (*c*) $K^\pm \rightarrow e^\pm + \nu + \pi^0$.

Category (2). Decays not involving neutrinos: (5) $\Lambda \rightarrow p + \pi^-$; (6) (*a*) $\Sigma^+ \rightarrow p + \pi^0$; (*b*) $\Sigma^+ \rightarrow n + \pi^+$; (7) $\Sigma^- \rightarrow n + \pi^-$; (8) (*a*) $K^\pm \rightarrow \pi^\pm + \pi^0$ (θ-mode); (*b*) $K^\pm \rightarrow \pi^\pm + \pi^\pm + \pi^\pm$ (τ-mode).

The decays in the second category involve 'strange' particles only and violate 'strange-ness' conservation. Thus these present the deeper problem.

Before considering experimental results, we wish to make some theoretical remarks regarding decays in category 1. From experience, one has learnt that the simplest procedure in neutrino theory is to consider only Majorana neutrinos (ψ). A Dirac (4-component) neutrino, ψ_D, is simply two Majorana neutrinos, ψ_1 and ψ_2, with a definite phase-relation between them ($\psi_D = \psi_1 + i\psi_2$). There are two independent basic assumptions which have been made in all present theoretical thinking, namely, (1) that the neutrino mass and self-mass are identically zero; and (2) that there is a conservation law for light particles (μ-mesons, electrons and neutrinos). In any process the total number of light particles minus anti-particles remains unaltered.

Specializing to the case of single Majorana neutrino, these two assumptions lead to the so-called 2-state theory[6]. In this theory: (*a*) Both parity as well as charge-conjugation invariance must be violated. (*b*) Neutrinos are polarized, either along (ν_R), or opposite (ν_L) to their direction of motion. ν_L may be considered as the anti-particle of ν_R ($\overline{\nu_L} = \nu_R$). (*c*) The electron (or positron) accompanying ν_R is right-polarized (with polarization of magnitude v/c) if the interaction is of 'vector' (V) or 'axial-vector' (A) type; it is left-polarized if the interaction is of 'scalar' (S), 'tensor' (T) or 'pseudoscalar' (P) type.

One may consider two completely independent Majorana neutrinos, ψ_1 and ψ_2, or a Dirac neutrino, $\psi_D = \psi_1 + i\psi_2$, obtaining further generalizations of the theory. In the latter case the distinction between a neutrino and anti-neutrino does not depend on the state of polarization of these particles ($\overline{\nu_L}$ and ν_R are both right-polarized but not identical).

Consider briefly the experimental data for processes in category 1 and their theoretical interpretation:

(1) $\mu \rightarrow e + 2\nu$.

(*a*) Experiments with electrons emitted by polarized μ-mesons show a backward–forward asymmetry, demonstrating parity non-conservation[2].

(*b*) The most accurate determination[7] of the Michel parameter, ρ, in the μ-decay spectrum gives a value of $0{\cdot}68 \pm 0{\cdot}02$. The 2-state theory predicts a value of $0{\cdot}75$ provided that, in μ-decay: $\mu^\pm \rightarrow e^\pm + \nu_L + \nu_R$.

(*c*) In the 2-state theory, writing the decay interaction in the form $g_V H_V + g_A H_A$, where V and A refer to vector and axial-vector couplings, $\{H_V = \overline{(\mu^+ Ve^+)}\ (\nu_R\ V\nu_L)$, etc.$\}$, the asymmetry parameter mentioned in (*a*) corresponds to equal V and A ($|g_V| = |g_A|$). The measurement of positron polarization and the result that these are right-polarized gives $g_V = -g_A$.

(*d*) The μ-mesons in these experiments were produced from π-decays at rest, and (in accordance with the expectation from 2-state theory) were nearly 100 per cent polarized. From the experimental observation that positrons from these μ^+-decays are emitted predominantly in the direction opposite to the μ^+-direction of motion[5], one may infer that μ^+-mesons from π^+-decay are also right-polarized.

(*e*) Assuming light-particle conservation, from $\mu^+ \rightarrow e^+ + \nu_L + \nu_R$, and $\pi^+ \rightarrow \mu^+_R + \nu_R$ (necessarily so from the conservation of angular momentum) one would infer that μ^+, e^+, ν_L form the set of 'particles' and μ^-, e^-, ν_R the set of 'anti-particles'.

It is to be noted at this stage that the 2-state theory gives no explanation of why $g_A = -g_V$.

(2) β-Decay:

As mentioned before, experiments with polarized nuclei demonstrate unmistakably that parity is not conserved. The fact that electrons and positrons emitted in β-decay possess a high degree of longitudinal polarization provides a new tool for the determination of the fundamental β-interaction. If the 2-state theory with lepton conservation is assumed, the experimental result that positrons are right-polarized implies that positrons are always emitted together with ν_R-neutrinos. This would mean that the β-interaction is A and V.

The experimental situation on this question is in confusion. First, most experiments seem to agree on the interaction being S or V plus A or T. This follows from the absence of Fierz-interference terms (plus the assumption of time-reversal invariance). The detailed distinction between S or V and T or A is made by electron–neutrino correlation experiments which have nothing to do with violation of parity as such. Experiments with argon-35 seem to show V, experiments with helium-6 show T; neon-19 and neutron data are compatible with either (S,T) or (V,A) combinations. It would appear that if the helium-6 experiments[8] stay firm, the 2-state theory with lepton conservation will have to be abandoned, notwithstanding its successes.

Turning to a consideration of decays in category 2, data have recently become available which demonstrate violation of parity in these processes also. The most conclusive evidence comes from $\Lambda \rightarrow p + \pi^-$. For a sample of polarized Λ-particles at rest, with spin pointing along $<\mathbf{J}>$, it is sufficient to show that the decay probability, W, depends on $<\mathbf{J}> \cdot \hat{\mathbf{p}}_{out}$ ($\hat{\mathbf{p}}_{out}$ is the direction of π-momentum). It transpires, providentially, that in the production reaction $\pi^- + p \rightarrow \Lambda + K$, the Λ-particles produced by π-mesons of about 1-BeV. energy possess a high degree of polarization. Since, quite generally,

$$<\mathbf{J}> \propto \mathbf{p}_{in} \wedge \mathbf{p}_\Lambda$$

where $\mathbf{p}_{in}$ is incident π^--momentum and p_Λ the Λ-momentum in the centre-mass frame, it is sufficient to look for an asymmetry in the number of decay π's in a direction normal to the Λ-production plane and in the opposite direction. Writing

$$W = 1 + \alpha <\mathbf{J}> \cdot \hat{\mathbf{p}}_{out}$$

the combined results of the Columbia, Bologna, Pisa, Michigan, Brookhaven and Berkeley groups give $\alpha\,\overline{<\mathbf{J}_\Lambda>} = 0{\cdot}52 \pm 0{\cdot}10$. Here $\overline{<\mathbf{J}_\Lambda>}$ is an average taken over a number of production angles. From angular distribution data in Λ-production it has been estimated that $\overline{<\mathbf{J}_\Lambda>} \leq 0.68 \pm 0{\cdot}03$, so that the fundamental asymmetry parameter[9], $\alpha \geqslant 0{\cdot}77 \pm 0{\cdot}15$. The corresponding results for Σ^+ and Σ^- particles give

$$\alpha\,\overline{<\mathrm{J}>_{e+}} = -\,0{\cdot}36 \pm 0{\cdot}20$$
$$\alpha\,\overline{<\mathrm{J}>_{e-}} = -\,0{\cdot}13 \pm 0{\cdot}26$$

The two decay modes of K^+-meson (θ-mode, $\pi^+ + \pi^0$, and τ-mode, $\pi^+ + \pi^+ + \pi^0$) provide additional evidence for violation of parity. The final state consisting of $\pi^+ + \pi^0$ mesons has spin-parity assignments 0 +, 1 −, 2 +, etc. It is easy to show that corresponding assignments for the $(\pi^+ + \pi^+ + \pi^-)$ state are 0 −, 1 +, 1 −, 2 +, etc. There is considerable evidence that the spin of the K-meson is zero. Thus, K-particles decay through two modes, with opposite intrinsic space-reflexion properties.

For the theoretical interpretation of 'strange'-particle decays there is nothing analogous to the neutrino to carry the blame for violation of parity. It may be recalled that it was the possibility of making the gauge transformation $\psi_\nu \rightarrow \gamma_5\psi_\nu$ for the neutrino (on account of its zero-mass) which led to the 2-state theory. One would like to have something analogous to this transformation for 'strange'-particles.

Already in neutrino physics there are indications that the transformation, $\psi_\nu \rightarrow \gamma_5\psi_\nu$, is not enough. There is the obstinate fact in μ-decay that $g_A = -\,g_V$. One can perhaps find a natural explanation for this by generalizing the neutrino gauge to electrons or μ-mesons, in the following manner. We postulate that all μ-interactions or electron-interactions are invariant for the transformations

$$\psi_e \rightarrow \gamma_5\psi_e, \quad m_c \rightarrow -\,m_e$$
$$\text{or } \psi_\mu \rightarrow \gamma_5\psi_\mu, \quad m_\mu \rightarrow -\,m_\mu$$

In so far as the electro-magnetic interaction is not changed by these (mass-reversal) transformations, invariance for mass-reversal appears as a universal law for all light particles.

Unfortunately, the current theories of strong interactions are not mass-reversal invariant. J. Sakurai[10] has, however, proposed that as a start towards obtaining the interaction for 'strange'-particle decays one may postulate that all 'strange'-particle decays arise from weak couplings of the type $(\overline{\Lambda} N)\ (\overline{N} N)$, where N stands for nucleons, and that mass-reversal applies to these. One then obtains the result that there exists a universal 4-field interaction between Fermi fields with equal mixtures of A and V. In the particular case of Λ-decay, this gives $\alpha = 0{\cdot}89$. This unified point of view appears attractive although it suffers from a number of theoretical objections. The chief experimental evidence against it, however, is the result of $e - \nu$ correlation experiments on helium-6 decay, mentioned before.

This discussion would not be complete without some mention of the so-called PCT theorem[11]. It can be shown that invariance of a theory for Lorentz rotations automatically implies its invariance under each of the six products PCT, TPC, PTC, etc., where P stands for parity, C for charge-conjugation and T for time-reflexion invariance. It is clear that —besides parity—at least one other invariance must be violated in weak decays. It can be shown that all experiments imply C-violation. Weak interactions are not charge-conjugation symmetric. It is still an open question whether or not time-reflexion symmetry holds in these processes.

VACANCIES AND OTHER POINT DEFECTS IN METALS AND ALLOYS

IN recent years there has been considerable interest in the behaviour of lattice vacancies, interstitial atoms and other more complex point defects in metals. In order to survey this subject, the Metal Physics Committee of the Institute of Metals invited six papers which would form the basis of a symposium. By kind permission of Sir John Cockcroft, the symposium was held at the Atomic Energy Research Establishment, Harwell. On December 9, following visits to the reactors DIDO and PLUTO and some laboratories, an introductory lecture was given by Prof. R. W. K. Honeycombe (University of Sheffield). He showed that a knowledge of the characteristics of point defects is necessary for the understanding of a wide range of metallurgical phenomena, including quench- and irradiation-hardening, fatigue and creep.

On December 10 the six invited papers were briefly presented to an audience of about three hundred, and general discussion followed. Dr. A. H. Cottrell (Atomic Energy Research Establishment, Harwell) considered how point defects can cause or contribute to hardening and softening processes in metals at temperatures lower than those at which conventional high-temperature creep occurs. The most spectacular hardening is that produced by quenching very pure metals from temperatures near the melting point. If the quench is sufficiently rapid, the high-temperature equilibrium concentration of vacancies remains randomly dispersed, and there is little or no hardening. Then if the metal is warmed sufficiently for the vacancies to agglomerate or migrate to dislocations, considerable hardening can occur. The detailed interpretation of quenching experiments was repeatedly shown to be of crucial importance for the understanding of the behaviour of lattice vacancies. When a metal is bombarded by energetic particles, occasional collisions lead to the knocking of atoms from lattice sites and the consequent production of equal numbers of vacancies and interstitials. The hardening produced by irradiation is often considerable, but the processes are apparently complex. It appears that both the initiation of plastic deformation and its continuation are usually made more difficult, indicating that point defects do interact with dislocations to give 'source hardening', and with each other to give general lattice hardening. During plastic deformation of annealed metals, lattice vacancies are produced and in certain circumstances can lead to readily observed increases in local diffusion rates. This is particularly prominent in fatigue, and it is probable that there is also a characteristic fatigue-hardening produced by point defects which more resembles quench- and irradiation-hardening than work-hardening.

The effects of point defects on some physical properties afford means for the study of their generation, movement and disappearance. The existing theoretical and experimental evidence was summarized by Dr. T. Broom and R. K. Ham (University of Birmingham). It was concluded that while the measurement of electrical resistivity is often experimentally simple, the uncertainties in interpretation are often such as to render more desirable the rather difficult measurement of stored-energy. The other properties considered were density, thermo-electric power, magnetic behaviour, thermal conductivity and nuclear magnetic resonance. The most useful experiments are obviously those in which the changes of many properties are studied simultaneously.

Dr. W. M. Lomer (Atomic Energy Research Establishment, Harwell) considered the transport of atoms through metallic lattices in various types of diffusion processes, of which vacancy diffusion is the most important. In many face-centred-cubic metals the details are well understood, but in other lattices the 'structure' of a vacancy and of other point defects remains uncertain and hinders agreement between theory and experiment. Vacancies in alloys usually associate preferentially with one species of atom, and useful information can be gained about this indirectly from quenching experiments and directly from tracer diffusion measurements in homogeneous alloys. It is probable that non-equilibrium concentrations of vacancies introduced into homogeneous alloys, for example, by irradiation, can only lead to accelerated diffusion over very small distances because of the density of vacancy traps. Chemical diffusion in inhomogeneous systems is more complex on account of the complication of the gradient of chemical potential. Briefly, each species of atom will migrate at a different rate along the gradient leading to shifting of diffusion interfaces, to 'vacancy pumping' and frequently to formation of porosity due to local vacancy supersaturations. The detailed behaviour of sinks (and sources) for vacancies is important not only in such systems but also in vacancy-creep and in sintering.

The activation energy for creep at high temperatures has frequently been found to be very close to that required for self-diffusion. In a general account of high-temperature mechanical properties, Dr. D. McLean (National Physical Laboratory) showed how this is accounted for by mechanisms involving climb of dislocations caused by their absorption of thermal vacancies. The relative rates of creep in various metals can be qualitatively explained by considering the structure of the dislocations involved and whether they can readily act as sinks for vacancies. Alloying usually reduces the rate of secondary creep, and it is possible by simple calculations to indicate what modifications to the dislocation climb model may occur in particular cases. During the later stages of creep tests, voids frequently appear at grain-boundaries. The hypothesis that these are formed by the condensation of vacancies is confirmed after critical examination of the conditions for nucleation and growth.

Dr. P. L. Pratt (University of Birmingham) contributed a paper discussing the role of point defects in determining the mechanical properties of ionic crystals. Historically, there is good precedent for such studies casting light on similar properties in metals, and it was shown that quench-hardening, generation of vacancies by moving dislocations, dislocation-pinning and vacancy cluster hardening all occur in crystals of sodium chloride. However, an important contribution to hardening in ionic crystals arises from the positive charge carried by dislocations which itself is a consequence of differing energies of formation of positive and negative ion vacancies. The line charges are screened by clouds of oppositely charged vacancies and this causes additional dislocation-pinning.

The last paper of the symposium, by E. C. Williams and P. C. S. Hayfield (Imperial Chemical Industries, Metals Division, Birmingham), dealt with the character of the metallic surface conceived of as containing an abnormal concentration of point defects and the influence that this has upon dry corrosion. Many new experimental results were presented from work in progress, and it was considered that they could best be explained by introducing into the theory of oxidation the concept of the trapping of electrons by localized structural defects.

In opening the general discussion, Prof. R. Maddin (University of Pennsylvania) gave new results for the hardening of polycrystalline copper by quenching. Specimens which had been rapidly quenched to room temperature could be hardened by slight warming, but heating at a higher temperature caused softening. Both processes occurred with an activation energy of 0·7 eV. and were believed to be associated with the movement of single vacancies. In a new theoretical interpretation of the effects of quenching on the electrical resistivity of gold it was proposed that quenching from low temperatures (~ 500° C.) produced single vacancies but that during quenching from high temperatures (~ 900° C.) some pairs, clusters and collapsed clusters (sessile dislocations) were created and then later modified appreciably the kinetics of annealing-out of the extra resistivity. Other experimental results were presented on the effect of straining and rate of strain on self-diffusion in silver single crystals. At appreciable rates of strain the activation energy for diffusion fell to ~ 0·7 eV., indicating this value as that required for the diffusion of vacancies produced by straining. Dr. M. C. Inman (National Physical Laboratory) gave some results for the effects of straining on the diffusion of antimony in copper and Dr. B. S. Berry (Fulmer Research Institute) for the energies for diffusion in quenched aluminium 4 per cent copper alloy.

Quenching of aluminium was discussed by M. M. Wintenberger (Vitry, France) both with reference to hardening and effects on electrical resistivity. Evidence was given which showed that annealing after a rapid quench gave a large residual resistivity and, because slight deformation reduced this, it was likely that it could be attributed to clustering of vacancies. The importance of clustering of vacancies in the hardening and subsequent softening of quenched sodium chloride crystals was emphasized by Dr. B. H. Kear (Tube Investments Research Laboratories). Describing work done at the University of Birmingham, he showed the effects of various quenching media, specimen sizes and quenching temperatures. After eliminating effects due to quenching strains there remained features closely analogous to those produced by single vacancies and vacancy clusters in metals.

Dr. T. H. Blewitt (Oak Ridge, temporarily at Harwell) referred to recent results in his own laboratory. Tensile tests on copper single crystals had been carried out at 20° K. in a nuclear reactor after maintaining the specimens at that temperature throughout a bombardment of 4×10^{17} neutrons. The hardening produced remained unchanged by pulse anneals up to about 250° K. despite the large drop of extra resistivity at $\sim 35°$ K. and its subsequent slow fall. Some slight decrease in critical shear stress occurred at $\sim 250°$ K. but complete annealing did not occur until higher temperatures. New measurements of the energy associated with the 35° K. resistivity-annealing process yielded 0·3 cal./mole for a bombardment of 4×10^{17} neutrons. Dr. Blewitt suggested that these results, taken in conjunction with his own previously published work on the effects of alloying on the 35° K. process in copper, precluded any simple interpretation of hardening as due to dispersed single vacancies and interstitial atoms. The annealing kinetics at 35° K. were apparently first order with a range of activation energies, and might provisionally be ascribed to the migration of crowdions.

The mechanisms of irradiation-hardening of copper after neutron bombardment were discussed by Dr. M. J. Makin (Harwell). His experiments on single crystals and polycrystalline copper showed that there is a large and temperature-dependent increase in the stress required to generate dislocation loops; this must originate from the interaction of one or more of the products of bombardment (vacancies, interstitials, etc.) with dislocations. In addition, there is a general lattice hardening (independent of temperature) which makes it difficult to maintain the movement of dislocations; this could be attributed to the clustering of point defects or to the formation of sessile dislocations. Some preliminary results were given for the effects of electron irradiations on the strength of copper single crystals. Evidence for the dual nature of irradiation-hardening was also given by Dr. A. T. Churchman (A.E.I. Research Laboratories, Aldermaston) in an analysis of the dependence of neutron-bombardment hardening of mild steel upon grain size and temperature, and by Dr. A. D. Whapham (Atomic Energy Research Establishment, Harwell), who showed photomicrographs illustrating the propagation of slip in lithium fluoride crystals hardened by electron bombardment. Dr. R. E. Smallman (Atomic Energy Research Establishment, Harwell) gave results showing how X-ray measurements indicate that a change occurs in the neutron bombardment of lithium fluoride at a critical dose of about 10^{17} nvt. Below this dose the lattice parameter increases with dose, but it remains constant above it; below, there are no diffraction streaks from single crystals and there is no line broadening and little low-angle scattering, but above 10^{17} nvt all these increase. Again, this may indicate condensation of point defects at high doses.

Various considerations suggest that such alternating strain as occurs during fatigue tests may be a prolific source of vacancies. R. K. Ham (University of Birmingham) presented new results which showed that the fatigue hardening of copper single crystals at room temperature is somewhat analogous to that produced by irradiation. Plastic flow in a tensile test following a fatigue treatment starts in the fatigue striae, and then at a stress some 30 per cent higher than the fatigue stress (and typically about 50 times higher than the critical stress of the virgin crystal) there is a small yield drop and a Lüders band passes through the crystal. The temperature-dependence of this fatigue hardening is high. Less-detailed results obtained for zinc crystals were described by Dr. G. B. Greenough (U.K. Atomic Energy Authority, Windscale). Dr. H. M. Rosenberg (University of Oxford) considered that electrical resistivity changes during fatigue of copper suggest that many more defects are created than during unidirectional deformation. The production of vacancies by unidirectional deformation is believed to be responsible for discontinuous flow in strain-ageing alloys: previous work has been done on dilute alloys, but S. G. Harris (University of Birmingham) showed how the Portevin–Le Chatelier effect in concentrated commercial and high-purity binary aluminium alloys is modified by a strain-induced precipitation process. This in turn can result in strikingly unusual 'shear' fractures after considerable plastic extension.

Recent experiments on copper bombarded with α-particles were described by Dr. R. S. Barnes (Atomic Energy Research Establishment, Harwell). On subsequent heating, bubbles of helium only appear where there is a prolific source of vacancies. The major sources of vacancies thus revealed are free surfaces and grain boundaries, with apparently only occasional dislocations. Dr. J. Nutting (University of Cambridge) suggested that, in technical creep-resisting alloys, vacancies could be produced as a result of the volume changes involved in the dissolution of small precipitates or their change in composition.

The analysis of new results for the creep of copper between 400 and 750° C. was discussed by Dr. P. Feltham (University of Leeds). Below a critical stress the rate of creep is controlled by the climb of edge dislocations, occasioned by the condensation of vacancies at jogs, and the activation energy is about 1·4 eV.; above the critical stress (identified as the strength of Cottrell–Lomer barriers) creep is controlled by the movement of screw dislocations containing jogs and the activation energy is about 2·2 eV.

Dr. A. B. Lidiard (University of Reading) contributed a discussion of diffusion in ordered alloys, and Dr. R. W. Cahn (University of Birmingham) indicated how in such alloys creep phenomena depend markedly upon the degree of order near the critical temperature.

Some criticism of the theory of Williams and Hayfield was offered by Dr. T. P. Hoar (University of Cambridge), who thought that their derivation of logarithmic oxidation rates could depend on other rate-controlling processes. New evidence for the effects of point defects on physical properties was given by Dr. H. M. Rosenberg (heat conductivity in strained α-brass single crystals) and by Dr. E. O. Hall (University of Sheffield) concerning effects of neutron-bombardment on the magnetic behaviour of single crystals of 2 per cent silicon ferrite. Fairly detailed analysis of the magnetic results was possible, and interpretations were offered in terms of an increase in density of dislocations and jogs and the creation of aggregates of point defects. T. Broom

INTERNATIONAL COMMISSION ON ENZYMES

AT the second general assembly of the International Union of Biochemistry, held in Brussels in August 1955, it was agreed to establish an International Commission to consider those problems of enzymology in which international co-operation would be useful, and especially to make recommendations for a more logical and a more generally satisfactory system for the nomenclature and classification of enzymes.

In the following year, Prof. M. Florkin, the president of the International Union of Biochemistry, called an *ad hoc* committee together in Paris. At this meeting it was finally agreed that the terms of reference of this Commission should in the first instance be: "To consider the classification and nomenclature of enzymes and co-enzymes, their units of activity and standard methods of assay, together with the symbols used in the description of enzyme kinetics". It was further agreed that the Commission should consist of ten ordinary members and two corresponding members. Dr. Malcolm Dixon was appointed president of the Commission and Prof. O. Hoffmann-Ostenhof secretary. Prof. E. Cherbuliez was present at this meeting as a representative of the Section of Biological Chemistry of the International Union of Pure and Applied Chemistry.

As a result of this meeting the following people agreed to serve on the Commission: *Ordinary members:* A. E. Braunstein (U.S.S.R.), S. P. Colowick (United States), P. A. E. Desnuelle (France), M. Dixon, president (United Kingdom), W. A. Engelhardt (U.S.S.R.), E. F. Gale (United Kingdom), O. Hoffmann-Ostenhof, secretary (Austria), A. L. Lehninger (United States), K. Linderstrøm-Lang (Denmark), F. Lynen (Germany); *Corresponding members:* F. Egami (Japan), L. F. Leloir (Argentine).

The work of the Commission was begun shortly after the appointment of members was completed, and a number of documents dealing with various different topics were circulated by the president and secretary for the consideration of the members.

The next meeting of the Commission took place in Paris in July 1957. One of the first pieces of business to be taken up at this meeting was a proposal by Dr. Gale that a philologist should be invited to participate in the work of the Commission. This somewhat novel and highly acceptable proposal was welcomed by the Commission, and Mr. H. S. Davies, Fellow of St. John's College, Cambridge, has now agreed to serve as a corresponding member. Although the work of the Commission is still in its early stages, a number of important decisions have been reached, and it is possible already to see the shape of the final recommendations. For example, it was agreed that a dual system of nomenclature should exist in enzymology, in which each enzyme should be given an exact systematic name, which in most cases will be a new name coined by the Commission, and also a short, trivial name, using for this, whenever possible, the present-day name. The systematic name for a given enzyme should as far as possible be descriptive of the reaction catalysed by the enzyme; thus, in the case of transferring enzymes the systematic name would be in accordance with the scheme 'donor–acceptor–group transferred–transferase', for example, alanine-α-ketoglutarate-amino-transferase, although 'transaminase' might well remain as a permissible trivial name. Enzymes catalysing oxido-reductions would be named oxidoreductases in the systematic nomenclature, according to the scheme 'donor–acceptor oxidoreductase', although again for everyday use it would probably be recommended that the terms 'dehydrogenase' and 'reductase' should be retained. A special sub-commission was set up to consider the nomenclature of cytochromes.

A preliminary discussion also took place on the question of the units of enzyme action and on the kinetic symbols to be used in the description of enzyme-catalysed reactions.

A joint meeting of the Commission on Enzymes with the Commission on Biochemical Nomenclature of the International Union of Pure and Applied Chemistry was also held in July, at which the nomenclature of 'pyridine nucleotides' was raised. It was agreed that the International Union of Pure and Applied Chemistry Commission should be asked to bring forward recommendations as to the naming of these compounds, so that the Commission on Enzymes would be provided with an internationally agreed terminology for this group of co-enzymes, and would therefore be in a position to deal with the nomenclature of enzymes functioning with these co-factors.

It would be misleading at this early stage in the work of the Commission to attempt to set down in any detail the recommendations that have been put forward. Much more work remains to be done, and in suggesting new proposals relating to nomenclature and classification of any group of compounds it is clearly necessary to view the field as a whole. One important practical point that faces any nomenclature Commission has already been discussed, namely, the means of bringing into general use the newly proposed names. Here it will, at some stage, be necessary to seek the help of the major biochemical journals in different countries, and it is to be hoped that the final recommendations of this Commission will be given the widest publicity in order to facilitate their adoption by working biochemists and so minimize the existing confusing and reduplication of names that exist in this field.

The Commission will welcome suggestions from non-members and from outside bodies on all aspects of the field. These should be sent to the president or to the secretary of the Commission, but it is hoped that they would not be published before being considered by the Commission.

O. Hoffmann-Ostenhof
R. H. S. Thompson

OBITUARIES

Mr. D. L. Chapman, F.R.S.

David Leonard Chapman, who died on January 17 at the age of eighty-eight, was little known personally outside the Universities of Manchester and Oxford, but the scientific work he quietly pursued for so many years was of the highest quality.

From Manchester Grammar School he went as an Open Exhibitioner to Christ Church, Oxford, and graduated with first-class honours in natural science in 1893. After teaching for a period at Giggleswick, he was appointed lecturer and demonstrator in chemistry under Prof. H. B. Dixon at the University of Manchester. In 1907 he was elected a Fellow of Jesus College, Oxford, to take charge of a new laboratory built by the College, which, because of the inadequacy of University laboratory accommodation, played a full part in the general teaching of chemistry in the University. The College laboratory remained open until his retirement in 1944.

In 1899 Chapman, who had excellent mathematical ability, published a paper of fundamental importance on maximum explosion-rates. Five years later similar results were obtained by Jouguet, and the two names have usually been associated in this field. The theory was a development of the mathematical results of Riemann and of Hugoniot, which showed that a discontinuity or 'shock wave' of very high velocity is set up in an explosion. This theory has proved both sound and valuable, and is still basic for modern work on explosion velocities. Chapman used it for calculating velocities for mixtures of nitrogen with electrolytic gas which were in excellent agreement with the experimental findings of Dixon; but since the theory required the knowledge of the magnitudes of high-temperature specific heats, which were then not obtainable directly, it did not for some years receive adequate recognition of its importance.

Early in the present century Chapman took up the study of the photochemical combination of hydrogen and chlorine, where investigators had found confusing results due to mysterious inhibiting effects. Long 'induction periods' were observed which appeared to vary in a very capricious manner from experiment to experiment. These were traced by Chapman to the presence of minute amounts of ammoniacal or other nitrogenous compounds in the water used in the reaction vessels, and a technique of high-temperature chlorine treatment was devised to minimize the irregularities. During the following forty years he continued a systematic study of this very difficult reaction, assisted by his wife Muriel (*née* Canning) and his research pupils. The effect of surface-area of the reaction vessel in affecting the dependence of the reaction-rate on the light intensity was carefully analysed. He also worked out the 'sector-technique' for finding chain-carrier lives by measuring the change of rate with sector speed, and applied it to the photochemical combination of hydrogen with bromine. In all this photochemical work he showed very great experimental skill in the planning and technique.

His approach to research was one of equal parts of penetration and caution; he was intensely honest and fair-minded, with a very clear vision of what had and what had not been proved. Although almost a recluse in scientific work, and indifferent to its reception by others, he was personally most friendly and approachable, and beloved by all his students. His high mathematical and experimental powers were recognized by his being brought into secret work on gaseous diffusion during the Second World War as part of the 'Tube Alloy' programme.

Chapman's absorption in scientific work did not prevent him from taking a part in College and University affairs. He never sought office or power, but in such positions he showed himself a practical administrator of great ability and common sense. For ten years he undertook bursarial duties in Jesus College, and acted as vice-principal from 1926 until his retirement. He also served as senior proctor and was from time to time a member of University boards and committees, including the Hebdomadal Council.

E. J. Bowen

Prof. Bjørn Helland-Hansen

Born in Oslo on October 16, 1877, Bjørn Helland-Hansen's advent to oceanographical science, in which he soon became a leading international figure, was almost fortuitous. The loss of most of his fingers by frostbite, while he was still a medical student in Oslo, induced him in 1898 to turn to the natural sciences. These he pursued in Oslo and, with oceanographical bias, particularly towards physical oceanography, also in Stockholm, where he sat under Vilhelm Bjerknes on dynamic meteorology and hydrography and where he met his life-long friend, V. W. Ekman, and in Copenhagen, where he worked with the already well-known Danish oceanographer, Martin Knudsen. Thus early, too, began his friendship and collaboration with Fridtjof Nansen, which produced two notable treatises on "The Norwegian Sea" and "The Eastern North Atlantic", in 1909 and 1927, respectively.

In 1900, Helland-Hansen was appointed assistant at the Norwegian Fishery Directorate in Bergen and for ten years participated in the cruises of its research ship, *Michael Sars*, the outcome of which, in 1912, was the oceanographical classic, "The Depths of the Ocean". In 1903, however, he made his own significant contribution to the developing science when, in collaboration with J. W. Sandstrøm, he derived the method which has since been extensively used for the dynamic computation of ocean currents.

In this same period, until 1914, Helland-Hansen was the brilliant leader of international courses in ocean researches which attracted marine scientists from far and near to Bergen; and in 1906, although primarily a physicist, he became director of the Marine Biological Station in Bergen. Four years later he was given the status of a university professor and approval to build a new research ship according to his own ideas. The *Armauer Hansen*, superseded only in 1957 by the appropriately named *Helland-Hansen*, was paid for entirely by the people of Bergen.

In 1917, as the result of his advocacy, the Geophysical Institute of Bergen, now part of the University of Bergen, was founded, and it is further significant of Helland-Hansen's sterling qualities that once again the new building occupied by the Institute in 1928 was paid for by citizens of Bergen. Besides being professor of oceanography, Helland-Hansen, until he resigned his professorship in 1946, was head of the Institute, which houses also Departments of Meteorology and of Cosmic Physics and Terrestrial Magnetism.

The scope and range of Helland-Hansen's enterprise and achievement embraced yet another project. In 1925 he was one of three trustees nominated by the testator to administer the residual estate of more than five million krøner of the late Christian Michelsen, a former Prime Minister of Norway and millionaire shipowner. As the Chr. Michelsen Fund, the estate endowed the establishment in 1930, and the maintenance, of a Chr. Michelsen Institute of Science and Intellectual Freedom. Besides compiling the statutes for its administration, Helland-Hansen, as chairman of the Board of Administrators, was for twenty-five years the presiding genius in its conduct.

He was the recipient of many honours, among which may specifically be cited the honorary rank of a Commander, with Star, of the Order of St. Olav, and the Portuguese Order of the Great Cross of St. Jago. He was doctor *honoris causa* of several universities and a fellow of numerous scientific and learned societies in Europe and America. Medals, in commemoration mostly of oceanographical research expeditions or investigators, were awarded him on many occasions. He was elected president of the International Association of Physical Oceanography in 1936 and president of the International Union of Geodesy and Geophysics in 1945.

Helland-Hansen died in Bergen on September 7, 1957, and the sympathy of countless colleagues, friends, and admirers the world over is offered to his widow, Anna Marie Krag, of Copenhagen, whom he married in 1902, and their family of one daughter and five sons.

J. B. TAIT

Prof. M. Damodaran

PROF. MANAYATH DAMODARAN, who died after a prolonged illness last December, was a graduate of the University of Madras, and after some preliminary training in research at the Indian Institute of Science, Bangalore, he was awarded a Government of Madras Research Studentship. He spent his first year in Germany with Abderhalden at Halle a.S., where he worked on the preparation and enzymic digestion of myristic acid peptides, and his last two years with me at the Imperial College of Science and Technology, London. He was then, as he always remained, a quiet unassuming scholar, and he already possessed the connoisseur's appreciation of research, a quality that his friends always found so attractive, and which inspired his own students later in Madras and Poona. Until recent years his main interest was in protein chemistry and metabolism, a field in which he was a pioneer in India and by far its best exponent. At heart he was an analyst and never happier than when applying his great experimental skill to problems concerned with amino-acid analysis of proteins.

At the Imperial College he was responsible, during 1929–32, for the isolation of asparagine and glutamine from enzymic digests of edestin and gliadin respectively, an achievement which provided the first direct proof of the 'amide hypothesis' in proteins and gained him the degree of D.Sc. (London). On his return to India at the end of 1932 he was made first reader and then professor in his old University at Madras, a post he held for sixteen years. There, in spite of very limited laboratory equipment, he embarked on a series of researches which soon made him one of the foremost biochemists in India. One may mention his work on phosphopeptone from casein, the isolation of canavanine from many seeds, new sources of urease, and the proteins of local foodstuffs. He also demonstrated for the first time the presence of glutamic dehydrogenase in plants, which he found in germinating seedlings. The results of all these valuable researches were accepted for publication in the *Biochemical Journal*.

In 1948 came the call to the new National Chemical Laboratory in Poona, where he was invited to assume directorship of the Biochemical Department and later the deputy-directorship of the Laboratory. At first the task was rather an uphill one, as accommodation was limited and equipment scarce. But in the early 1950's, with the new building in operation, conditions improved, and during his last five years or so Damodaran had at his disposal a laboratory as well equipped as any in Europe or America. The National Chemical Laboratory had been created to fulfil a national need, and Damodaran never lost sight of this aspect of his job. In the early stages of its development, proteins had to be relegated to the background and prominence given to problems that might have economic or medical application. For example, he bred a remarkably active and reliable strain of *Aspergillus niger* for the production of citric acid from sugar, and his process based on it is now in commercial operation. The synthesis of ascorbic acid from sorbitol, with a 99 per cent intermediary yield of sorbose, has also passed the pilot stage. Another important line he introduced was a gelatin plasma substitute preparation, based on a tryptic digestion, which has already been tested clinically with excellent results. Damodaran entered whole-heartedly into the work of the National Chemical Laboratory, and his retirement through ill-health in the summer of 1956 was deeply regretted by the Director and all his staff. All who knew him in Britain and India will mourn the passing of a very lovable colleague.

A. C. CHIBNALL

Prof. Claude Fromageot

CLAUDE FROMAGEOT, director of the Laboratory of Biological Chemistry at the Faculté des Sciences, Paris, since 1946 and professor of biochemistry at the Sorbonne since 1954, died on January 10, at the age of fifty-eight. The unexpected loss of this distinguished scholar comes as a great shock to his many friends all over the world.

Fromageot received his early scientific education at the Institut National Agronomique. After a year at the Collège de France, he spent a further year as assistant to Victor Henri at Zurich. In 1928 he went as a Rockefeller Fellow to Berlin-Dahlem, where he worked in the laboratory of Carl Neuberg. In 1929 he became director of the Biochemical Laboratory at the Faculté des Sciences at Lyons, and there he remained (with an interruption of ten months in 1933 spent at the University of Wisconsin, in Madison) until he went to Paris in 1946.

His early work was devoted mainly to the study of bacterial fermentations, particularly to the relation between fermentation and respiration in *Propionebacterium pentosaceum*. In later years he became interested in the study of the chemical composition of proteins endowed with biological activity; for example, of lysozyme and of the pituitary hormones. Some of his more recent results in this field were presented at Bristol in April 1956, when he took part in the Colston Research Society Symposium on the neurohypophysis.

Fromageot's name is most intimately connected with our present knowledge of the metabolism of sulphur, both in micro-organisms and in higher animals. Much of this work was reviewed in his Harvey Lecture, given in New York in 1953. One of the main advances that we owe to him and his colleagues is the recognition of the central position held by cysteinesulphinic acid in the degradation of cysteine. They discovered and investigated a number of enzymic reactions in which this important intermediate metabolite takes part. The role of vitamin B_6 in these reactions and the action of hormones on the enzymes involved have been studied in his laboratory. Many of these results are embodied in the "Colloque sur la Biochimie du Soufre", the outcome of a gathering held in May 1956 at the Station Maritime, Roscoff, under the auspices of the Centre National de la Recherche Scientifique, where Fromageot and his colleagues discussed outstanding problems with other workers in this field. Here his unique mastery of the subject was evident, and this volume will now serve to remind us of some of his more recent achievements and of his aims. At the time of his death, Fromageot was busy planning another session on sulphur metabolism for the Fourth International Congress of Biochemistry, to be held at Vienna this year.

Fromageot did much to strengthen international co-operation in research. He travelled widely and lectured in many countries, helped by his great linguistic abilities. Biochemists everywhere owe him a debt, as one of the founders of *Biochimica et Biophysica Acta*, and as the president of the Organizing Committee of the Second International Congress of Biochemistry, held at Paris in 1952.

In the remarkable development of French biochemistry in the post-war years, Fromageot played his full part. Some of his earlier colleagues followed him from Lyons to Paris; later his name attracted an ever-increasing number of workers from France as well as from many other countries. He was able in recent years greatly to develop his laboratory from its modest beginnings and to provide it with modern equipment. It is sad to think that his untimely death did not allow him to direct for a longer period what had grown into one of the world's leading centres of biochemical research. H. BLASCHKO

NEWS and VIEWS

Entomology at McGill: Prof. E. M. DuPorte

PROF. E. M. DUPORTE, who is retiring from the chair of entomology at MacDonald College, McGill, was born on the island of Nevis in the British West Indies and received his first college education at Basseterre on St. Kitts. He went to Canada in 1910 as a student at Macdonald College and has been attached to that institution either as a student or as a member of the staff throughout his academic life. He took his Master's degree in 1914 and his Ph.D. in 1921. Morphology became his principal interest, and his world-wide reputation was earned in this field. Prof. DuPorte has played an important part in establishing and maintaining the reputation of Macdonald College as a graduate school. He taught a remarkably wide range of subjects: ecology, protozoology, histology, parasitology, insect taxonomy, morphology, physiology, comparative vertebrate anatomy and embryology, and was one of the two members of the committee responsible for the establishment of the present Institute of Parasitology at Macdonald College. In spite of his wide range of interests in his own subjects, he has still found time for other activities, and is a keen golfer as well as a puppet player who builds and handles his own puppets. His friends and students thoroughout Canada will wish him a happy and enjoyable retirement.

Dr. D. K. McE. Kevan

THE appointment of Dr. D. K. McE. Kevan to succeed Prof. DuPorte at Macdonald College, McGill, will be welcomed by his many friends in Britain and Europe. Dr. Kevan graduated from the University of Edinburgh with first-class honours in zoology in 1941, and proceeded to the Imperial College of Tropical Agriculture, Trinidad, where he obtained his associateship in 1943. He was then appointed to the Colonial Service, and stationed in Kenya, where he became interested in the problems of the taxonomy of locusts and other bush hoppers. These have remained his abiding interest, and in a series of able papers he has undertaken considerable revision of the classification of certain Orthoptera, especially Chrotogonus, and has brought some degree of order to what had been a confused and tangled field.

He returned to England in 1948 as the senior member of the agricultural zoology section of the youngest Faculty of Agriculture in Britain, at the newly established University of Nottingham. In this, his first teaching post, he quickly established a reputation as an able teacher, and he played an active part in developing the curriculum for the new structure of the degree. He has been active both in the prosecution and in the encouragement of research, and a remarkable stream of papers has flowed from his department. His work in taxonomy has been assisted by a wide knowledge of foreign languages which is becoming unusual in a scientist, and papers in both German and French testify to his fluency. More recently he has become interested in soil zoology and has developed an effective undergraduate course in this field, while his own key for the identification of soil-inhabiting fauna, published with the Proceedings of the Second Nottingham Easter School in Agricultural Science, constitutes something of a classic. A critical and independent mind, he has been an admirable tutor, whose succinct reports on the vagaries as well as the virtues of both male and female students will be sadly missed by his colleagues at Sutton Bonington.

Civil Engineering at Nottingham: Dr. R. C. Coates

DR. R. C. COATES, who was appointed to the newly established chair of civil engineering in the University of Nottingham on January 1, began his education at

New Mills School and the Herbert Strutt School, Belper, Derbyshire. After a period of articled pupillage with Waude Thompson, borough engineer and surveyor, Mansfield, Nottinghamshire, Dr. Coates entered University College, Nottingham, and read for a degree in civil engineering. He then worked with Messrs. Lehane, Mackenzie and Shand, Ltd., as an engineer on factory construction for the Ministry of Supply, before joining the Corps of Royal Engineers during the Second World War, in which he served in the Mediterranean theatre. On demobilization, he worked as an engineering assistant to Mansfield Corporation, until appointed lecturer in civil engineering at University College, Nottingham, late in 1946.

He has carried out research on the fatigue strength of compression-type coil springs, and was awarded the Ph.D. degree of the University of Nottingham in 1953. In the same year he was appointed senior lecturer responsible for civil engineering in the joint Departments of Civil and Mechanical Engineering. Dr. Coates's research has included the fatigue of metals and structural analysis. In recent months he has co-operated with Mr. C. E. E. Gibson, county architect of Nottinghamshire, in the design of buildings to resist mining subsidence, and with Mr. L. E. Richardson, chief civil engineer to the East Midlands Division of the Central Electricity Authority, on the design of the experimental power station using coal gasification at Newman Spinney.

National Physical Laboratory, Ship Division : Dr. F. H. Todd

Dr. Frederick Henry Todd has been appointed superintendent of the Ship Division of the National Physical Laboratory, in succession to the late Dr. J. F. Allan (*Nature*, **180**, 68; 1957). Dr. Todd, who graduated from King's College, Newcastle upon Tyne, was at the National Physical Laboratory for twenty years before going to the United States in 1948 to become chief naval architect at the David Taylor Model Basin, Washington, D.C. Before the Second World War, Dr. Todd did much work on hull and propeller design and hull vibration for all classes of merchant ships and among his war-time activities were the testing and development of units of 'Mulberry' harbour. While in the United States he was responsible for the technical direction of the U.S. Bureau of Ships' hydrodynamics research programme in a variety of fields, including research into the hull-form of single-screw ships. Dr. Todd is returning to the National Physical Laboratory at a time of great activity in the Ship Division. The new Ship Hydrodynamics Laboratory, now under construction at Feltham at a cost of £2 million, together with present facilities, should make the National Physical Laboratory one of the best-equipped establishments in the world for ship research work. Dr. Todd spent his last year at the National Physical Laboratory before going to Washington working on a preliminary design of the main features and layout of this Laboratory.

British Trust for Ornithology : Mr. K. Williamson

The British Trust for Ornithology has received a five-year grant from the Nuffield Foundation, enabling it to appoint a migration research officer to carry out the work of analysing past observations and to make recommendations for the future. Mr. Kenneth Williamson, who has accepted the appointment, was during 1948–56 the director of the bird observatory on Fair Isle (between Orkney and Shetland) and last year spent a season on St. Kilda as warden for the Nature Conservancy. Previously he had extensive museum experience and served during the Second World War in the Faeroe Islands. During his time on Fair Isle, Mr. Williamson not only carried out extensive bird-ringing activities and day-to-day observations, but also made a particular study of the effect of the weather on migratory movements. He also studied the ectoparasites of birds as providing a possible clue to their place of origin and for several years he followed the fortunes of a breeding colony of the parasitized Arctic skua, a bird of great interest to biologists because of its two plumage phases. Mr. Williamson's first task will be to arrange for the copying by some photographic method of the massive observations accumulated by the bird observatories. In June he, with other officials of the British Trust for Ornithology, will attend the twelfth International Ornithological Congress in Helsinki and will read a paper on the work of the British bird observatories.

The International Atomic Energy Agency

A number of offers of fissionable materials, radioelements and special materials for reactors, and fellowships and training facilities, have been officially communicated by member States to the headquarters of the International Atomic Energy Agency at Vienna, for use in atomic energy programmes to be carried out under its auspices. The prices and conditions on which the materials are to be made available to the Agency have yet to be determined. Canada has informed the Agency that, for several years at least, it could provide the natural uranium necessary for its atomic energy programmes, while India states that it could supply all the thorium needed ; Ceylon has offered 30 tons of refined monazite of about 9 per cent thorium content ; Norway has offered to supply isotopes produced in the Norwegian reactor at Kjeller, which is operated in collaboration with the Netherlands, and special reactor materials such as niobium, aluminium and molybdenum ; Portugal has made available to the Agency 100,000 kgm. of uranium oxide in concentrate form ; South Africa is prepared to supply uranium oxide concentrates, beryllium, lead, tantalum, cadmium, lithium, vanadium, chromium and nickel ; the U.S.S.R. has offered 50 kgm. of contained uranium-235 in any concentration up to 20 per cent, and is prepared to make available further supplies of fissionable and other materials ; the United Kingdom has offered 20 kgm. of contained uranium-235 ; and the United States of America has offered 5,000 kgm. of contained uranium-235, and will also make available nuclear materials equal in quantity to the total amount of such materials supplied by other members of the Agency, and on equivalent terms, up to July 1, 1960. Contributions of 250,000 dollars have also been offered to the fellowships fund and several member States have placed at the disposal of the Agency fellowships and training facilities to be taken up in the countries offering them. The United States has also announced its intention of presenting a technical library to the Agency.

Molecular Physics

The editor, Prof. H. C. Longuet-Higgins, and the associate editor, Dr. J. H. van der Waals, of the new journal, *Molecular Physics* (1, No. 1; January 1958. Pp. 98. Published quarterly. Annual subscription: 95*s.*; 13.30 dollars. Single issues: 25*s.*; 3.50 dollars. London: Taylor and Francis, Ltd., 1958), state in their brief editorial to the first number that the subject of molecular physics occupies a key position in modern science and that the frontier between physics and chemistry is disappearing as the methods of physics are brought to bear on the problems of chemistry. Probably not all chemists and physicists would agree with this rather bold statement; nevertheless they would agree that the introduction of a periodical devoted solely to contributions on the structure and physical properties of molecules is timely. Papers on molecular structure and dynamics, the electric and magnetic properties of molecules, and the processes of molecular excitation, ionization and dissociation, and the equilibrium transport and relaxation properties of molecular assemblies, will be particularly welcome, in addition to research notes. The first number contains ten articles and one research note. These deal with such subjects as nuclear magnetic resonance in substituted ethanes; dipole moments of azines; critical opalescence in solid solutions; and six papers are devoted to theoretical problems, mainly of a mathematical nature, in quantum and statistical mechanics. One paper is in German, but all have abstracts in English, French and German. The format is similar to, and of the high standard associated with, other such scientific journals as the *Philosophical Magazine* published by Taylor and Francis, Ltd.

Science and Education

An important statement on policy has been issued by the Committee of the Science Masters' Association (pp. 12. London: John Murray (Publishers), Ltd., 1957). Recognizing that science must be taught as a major human activity and as a cultural study of supreme importance because of its effects on human life and thought, the Committee suggests that the aims of science teaching should be three-fold: to lead pupils to observe, and to solve problems by controlled experiments, to draw conclusions from observations, and to appreciate the systematic laws and principles of science; to give knowledge and understanding of the origins and development of science, of the achievements of scientific pioneers and of the implications, now and in the future, of modern scientific and technological developments; and for science specialists, to provide a suitable preparation for further scientific or technological education. The Committee recommends that all pupils should devote the same time to science subjects up to the end of the fifth-form year; that all sixth-form pupils should follow a cultural course in science and that subject-specialization should be retained in sixth forms and that science syllabuses at Advanced Level should be reduced in factual content. The recommendations raise many problems of syllabuses, of teaching methods, of suitable training for science teachers, and of examinations which will be examined in a future report.

Clouds on Filmstrip

Two filmstrips entitled "Clouds", accompanied by a 20-page booklet of lecture notes by F. H. Ludlam and Dr. R. S. Scorer of the Imperial College of Science and Technology, London, have been produced by Diana Wyllie, Ltd. (18 Pont Street, London, S.W.1), in co-operation with the National Committee for Visual Aids in Education. In recent years much has been learned about the motions of the air and properties of the water droplets and ice crystals which compose the clouds, the growth and decay of which can be used to exemplify many branches of physics. The filmstrips, which are in colour, and made in many cases from photographs of great beauty, are chosen principally to illustrate the process of development of various types of cloud rather than their classification. The colour suffers slightly in the reproduction process, which, however, also tends to increase the contrast between cloud and sky, with advantage. The filmstrips, which deal respectively with haze (in relation to condensation nuclei), convection clouds and ice clouds (24 frames) and with layer, wave and billow clouds, with three explanatory diagrams (25 frames), are intended chiefly for use in schools and universities.

Nucleonic Thickness Gauge

Baldwin Instrument Co., Ltd., Dartford, Kent, has published details of a new nucleonic thickness gauge for use in the cold-rolling of copper, brass or steel strip. The instrument can be used for thicknesses of steel up to 0·40 in., which is claimed to be about twice the upper limit for the normal β-ray gauge. This increased range is obtained by using bremsstrahlung emitted when β-rays from strontium-90 impinge on a metal target. The intensity of the radiation after passing through the strip, which is related to strip thickness, is measured by the intensity of the scintillations produced in a sodium iodide crystal. The instrument would appear to be well suited to automatic gauge control, for which it feeds a bridge circuit that indicates the deviation of thickness from any desired value. When this deviation reaches a predetermined level, the screw-down mechanism of the mill is brought into operation. The intervals during which no strip is passing through the mill are utilized for automatic standardization.

Bibliography of the Mysidacea

A useful "Bibliography of the Order Mysidacea", which is carried up to the end of 1955, has recently been prepared by Joan Gordan (*Bull. Amer. Mus. Nat. Hist.*, 112, 279; 1957). It is divided into three sections; the first, containing about 1,180 entries going back to O. F. Muller (1776), is a list of references arranged alphabetically. The second part is a list of the recorded species arranged in alphabetical order in their genera, which again are arranged alphabetically and grouped under five families. Under each species are listed the relevant page references in order of their date of publication. This arrangement makes it very easy to refer to the literature of any species for it includes the synonymy by cross-reference. The author points out that the work is not intended as a contribution to the systematics or taxonomy of the order and accepts the works of W. M., and W. M. and O. S. Tattersall (both of 1951) for these purposes. The third part arranges the literature under ten arbitrary but acceptable headings. That for distribution is subdivided into "Fresh and Brackish Water" and "Oceanic", and then each category is further divided into geographical regions. The printing and format are of the usual excellence of the *Bulletin* and the author is to be congratulated on a commendable contribution that will save future workers on the order a great deal of time.

Mond Nickel Fellowships

THE Mond Nickel Fellowships for 1957 have been awarded to Mr. E. J. Williams (John Summers and Sons, Ltd.) and Mr. R. J. D. Acheson (Mufulira Copper Mines, Ltd.). The Committee now invites applications for Fellowships of an approximate value of £900–£1,200 for 1958. Fellowships will be awarded to selected candidates of British nationality with degree or equivalent qualifications to enable them to obtain wider experience and additional training in industrial establishments, at home or abroad. Further information can be obtained from the Secretary, Mond Nickel Fellowships Committee, 4 Grosvenor Gardens, London, S.W.1. Completed application forms are required by June 1.

Progress in Atomic Power

THE United Kingdom Atomic Energy Authority is to hold a Conference at Harwell on June 11, at which recent developments in nuclear reactor technology will be discussed with representatives of British industry. Accommodation will be available for about two hundred representatives from industry. Requests for further details and for reservations should be made to the Director (Industrial Liaison Office), Building 329, Atomic Energy Research Establishment, Harwell, Nr. Didcot, Berkshire, not later than March 15.

Gordon Research Conferences

THE Gordon Research Conferences for 1958 will be held during June 9–August 29 at Colby Junior College, New London, New Hampshire; New Hampton School, New Hampton, New Hampshire; and Kimball Union Academy, Meriden, New Hampshire. The Conferences, established to stimulate research in universities, research foundations and industrial laboratories, consist of informal meetings, scheduled lectures and free discussion groups intended as a means of disseminating information and ideas which otherwise would not be realized through the normal channels of publication and scientific meetings. No publications are prepared as emanating from the Conferences, attendance at which is limited to one hundred persons. The programme includes ceramics, chemistry, structure and physiology of bones and teeth, magnetic resonance, nuclear chemistry, radiation chemistry, toxicology and safety evaluation, and corrosion. Requests for additional information, or applications to attend, should be addressed to W. George Parks, Director, Department of Chemistry, University of Rhode Island, Kingston, Rhode Island.

Aeronautical Research

THE Combustion and Propulsion Panel of the Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization, will hold its third colloquium in Palermo, Sicily, during March 17–21. The meeting will be largely devoted to consideration of current propulsion problems. Five themes will be developed during the meeting, with one day devoted to each. They are: power plant requirements related to aircraft mission; interaction of the combustion systems with other engine components; noise; combustion; aerophysical chemistry.

The Group's Wind Tunnel and Model Testing Panel will also sponsor a meeting, in Freiburg im Breisgau, Germany, during April 22–25. The subjects which will be discussed during the four-day meeting will include the historical development of ballistics, high-velocity guns, range techniques and long-range missiles.

Lady Tata Memorial Trust Scholarships and Fellowships

THE Trustees of the Lady Tata Memorial Fund invite applications for grants, scholarships or fellowships for research on diseases of the blood, with special reference to leukæmia, in the academic year beginning on October 1. In view of the affinity between leukæmia and other forms of neoplastic disease, candidates with programmes of research on any aspect of malignant disease which may throw incidental light on problems of leukæmia will be eligible for consideration. Grants of variable amount are made for research expenses or to provide scientific or technical assistants for senior workers. Scholarships are awarded for the personal remuneration of workers carrying out approved research under suitable direction; their normal value will be £600 per annum. In addition, the Trustees may award one or more Lady Tata Memorial Research Fellowships to workers with considerable research experience, with stipends of £1,200 per annum. Further particulars and forms of application may be obtained by writing to the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London, S.W.3. Applications must be submitted before March 31, and the awards will be announced by the Trustees in June. The grants, scholarships and fellowships offered by the Trust are open to suitably qualified investigators of any nationality, working in any country in which it will be possible to make payments in the coming academic year.

Oversea Service Division, Colonial Office

THE following appointments have recently been made in the Oversea Service Division, Colonial Office: H. B. Ambrose (agricultural officer, Kenya), research officer, Nyasaland; A. de K. Frampton (agricultural adviser to the controller, Development and Welfare Organizations, Barbados), deputy director of agriculture, Barbados; V. E. Gale (principal agricultural officer, Western Nigeria), assistant director of agriculture, Western Nigeria; L. Green (field officer (agriculture), Uganda), senior field officer (agriculture), Uganda; V. R. James (assistant superintendent of public gardens, Jamaica), superintendent of public gardens, Jamaica; G. S. Scott (provincial tsetse officer, Tanganyika), agricultural officer, Uganda; W. S. Steel (entomologist, Game and Tsetse Control Department, Northern Rhodesia), chief entomologist, Game and Tsetse Control Department, Northern Rhodesia; W. E. Lewis (assistant conservator of forests, Nyasaland), conservator of forests (Division of Afforestation), Nyasaland; J. L. Masson (assistant conservator of forests, Northern Nigeria), senior assistant conservator of forests, Northern Nigeria; C. A. M. Nash (assistant conservator of forests, Northern Nigeria), senior assistant conservator of forests, Northern Nigeria; I. Paul (assistant conservator of forests, Sierra Leone), senior assistant conservator of forests, Sierra Leone; J. D. Todd (assistant conservator of forests, Mauritius), assistant conservator of forests, Northern Rhodesia; L. H. Myers (assistant director of surveys, Jamaica), supernumerary deputy director of surveys, Jamaica; P. D. L. Guilbride (veterinary investigation officer, Jamaica), deputy chief research officer, Uganda; M. A. Petris (veterinary officer, class 2, Cyprus), veterinary officer, class 1, Cyprus; P. J. Sheehy (veterinary officer, Northern Rhodesia), deputy director of veterinary services, Northern Rhodesia; E. Jones, chemist, Agricultural Department, Northern Nigeria; Lieut. Col. C. H. Keenlyside, land settlement officer, Nyasaland; B. H. Kenten, biochemist, West African Cacao Research Institute, Ghana; J. F. Longworth, agronomist, West African Cacao Research Institute, Ghana; W. I. Powell, agronomist, Somaliland; W. Smith, supernumerary agricultural engineer, Mauritius; D. G. Thomas, senior botanist, Uganda; W. J. Evans, assistant conservator of forests, Northern Nigeria; C. S. Feilberg, assistant conservator of forests, Northern Nigeria; B. J. Rushton, chemist, Geological Survey, Tanganyika; R. C. Sansom, assistant geologist, British Guiana; S. S. Brunton, veterinary officer, Northern Rhodesia; P. B. Capstick, veterinary research officer, Kenya; J. Dickson, veterinary research officer, Federation of Nigeria; D. G. Erskine, veterinary research officer, Federation of Nigeria; O. G. H. Karst, veterinary officer, Northern Nigeria; K. A. Ross, veterinary officer, Northern Rhodesia; L. A. Stephens, veterinary officer, Kenya.

University News: Glasgow

PROF. J. MONTEATH ROBERTSON has been granted leave of absence to enable him to hold a visiting professorship in the College of Chemistry at the University of California, Berkeley. He will give a short course of lectures on the chemical significance of recent developments in crystal analysis, and will be away for about one month from the middle of March. Leave of absence has also been granted to Dr. E. Gelles for six months, during which time he will hold a research fellowship at Brandeis University, Waltham, Massachusetts. Dr. G. A. Sim has been appointed to a lectureship in chemistry, and Dr. W. M. Fairbairn has resigned his lectureship in mathematics in order to take up a lectureship at the Manchester College of Science and Technology.

London

DR. H. G. EGGLESTON, lecturer in the University of Cambridge, has been appointed to the University chair of mathematics tenable at Bedford College. Dr. Mary Barber has been appointed to the University readership in clinical bacteriology tenable at the Postgraduate Medical School of London and the title of reader in mathematics in the University of London has been conferred on Dr. M. A. Jaswon, in respect of his post at the Imperial College of Science and Technology.

Announcements

DR. H. R. C. PRATT has recently taken up an appointment as leader of the chemical engineering section in the Division of Industrial Chemistry, Commonwealth Scientific and Industrial Research Organization. Dr. Pratt was formerly chief scientific officer at the U.K. Atomic Energy Research Establishment at Harwell and was senior group leader of the Chemical Engineering Division.

THE Trustees will consider in June applications for a Ramsay Memorial Fellowship for advanced students of chemistry. The value of the Fellowship will be £600 per annum, to which may be added a grant for expenses of research not exceeding £100 per annum. The Fellowship will normally be tenable for two years. Further information can be obtained from the Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1. Completed applications must be received not later than April 18.

A SYMPOSIUM on "The Design of Teaching Laboratories in Universities and Colleges of Advanced Technology" will be held at the Royal Institute of British Architects on March 14. The chairman will be Sir Keith Murray. Further information can be obtained from the Secretary, Royal Institute of British Architects, 66 Portland Place, London, W.1.

AN informal discussion on "The Practice of Light Scattering" will be held in the Chemistry Lecture Theatre, Chemistry Department, University of Birmingham, on April 25. The discussion is intended to be entirely informal and to consider the experimental techniques employed in applying the light-scattering method to the study of solutions of both synthetic and biological macromolecules. Further information can be obtained from Dr. F. W. Peaker, Chemistry Department, The University, Birmingham 15.

AN international congress on nuclear physics will be held in Paris, during July 7–12, under the patronage of the International Union of Pure and Applied Physics and of Unesco. The title of the congress is "Low Energy Nuclear Interactions and Nuclear Structure". Its purpose is to gather theoretical and experimental information in the energy range lower than the threshold for meson creation. Further information can be obtained from the Congrès International de Physique Nucléaire, Institut du Radium, rue Pierre Curie, Paris, 5 ème.

THE Linnean Society of London is to hold a symposium on the biological uses of the electron microscope on March 28, with a possible extension to the morning of March 29. The object of the meeting is to enable biological workers (including those engaged in the cognate medical sciences) who are not themselves experts in the use of the electron microscope to learn something of the biological applications of that powerful research tool. Biologists who are not members of the Society should inform the General Secretary, Linnean Society, Burlington House, London, W.1, before February 28 if they desire to attend.

THE Federation of British Industries is to hold a Conference on Nuclear Energy under the chairmanship of Sir Claude Gibb (managing director, C. A. Parsons and Co., Ltd.) at the Grand Hotel, Eastbourne, during April 10–12. The Conference, which aims at conveying an understanding of the industrial potentials and applications of nuclear power to directors of firms in fringe industries, will include a visit to the Atomic Energy Research Establishment at Harwell. Further details can be obtained from the conference secretary, Mr. P. J. C. Perry, Federation of British Industries, 21 Tothill Street, London, S.W.1.

ERRATUM. In the communication entitled "Action of Ethylene Dibromide on Hen Gonadotrophic Hormones" by Dr. Eugenia Olomucki, published in *Nature* (180, 1358; 1957), the daily amount of follicle-stimulating hormone injected into hens was 1·4 mgm. (and not 14 mgm., as printed).

BRITAIN'S COAL AND ITS FUTURE

THE pace at which the material conditions of civilization are changing at the present time is unique in recorded history. Prof. Arnold Toynbee has contended that throughout the 5,000 years up to the past century these conditions, and the human outlook, remained fundamentally the same. But the rapid acceleration that began with the industrial revolution is now so far-reaching that it may herald a change in kind rather than of degree in the affairs of mankind ; accompanied, it is to be hoped, by an increased capacity for understanding and controlling the new environment. Though this general picture is true only of the industrial nations, none can long continue unaffected whether it participates in the process of industrialization or not. Prof. P. M. S. Blackett, in his recent presidential address to the British Association, has suggested that an investment of about £1 per head of population per annum is required initially to enable a society to 'take off' in this sense and gather the necessary momentum.

Nowhere is this acceleration more apparent than in the basic activities of fuel production and consumption. Industry has developed chiefly on energy from coal over some 200 years ; oil has become important during the past forty years and nuclear energy is providing the latest example of rapid growth. Other sources of energy have been, and are likely to remain, relatively unimportant in the broad picture. Oil has natural advantages, such as its convenience in use whether in the mobile internal combustion engine or as furnace fuel ; and, in addition to its energy value, the demand for certain fractions as lubricants is by no means negligible. It is thus the coal industry that may be most affected by the changing relative importance of these three sources of energy.

There is considerable misconception about the likely effects of these changes within the present century ; the quantity of coal used is very great, and nuclear energy, however rapidly developed, seems unlikely to shoulder a major part of Britain's power load before the final decades. Recent authoritative forecasts have predicted that the use of coal in the United States may be at least doubled over the next twenty years, though ultimately there may be some decline in consumption. In Britain, the change is unlikely to be spectacular, but an increase is to be expected in the immediate future. The large uncertainties that necessarily attend even the most careful attempts to foresee the overall trends and the detailed shifts in the modes of coal consumption thus pose many problems, not least to those responsible for both long- and short-term research on coal utilization.

It was in relation to this background that Dr. J. Bronowski, director of the Coal Research Establishment of the National Coal Board, delivered to the Royal Institute of Chemistry the tenth Dalton Lecture, entitled "Coal and Coal Chemicals in the National Economy", at the Manchester Town Hall on October 25. The large audience comprised, as well as scientists, a wide cross-section of the public led by the Lord Mayor ; and a well-designed exhibition relevant to the subject was arranged in the nearby public library by the Institute and the National Coal Board with the support of other organizations.

Dr. Bronowski's lecture consisted of a thoughtful analysis of trends in the material basis of life with special reference to fuel, their extrapolation into the future, and their bearing on current research policy. He demonstrated that the standard of living of a society is related in precise detail to its degree of mechanization ; as measures of mechanization, steel and energy consumption per unit of population, representing respectively indices of material being processed and of energy used in processing it, are both satisfactory. For reasons that are obvious, food consumption as a measure of standard of living tends to rise to a maximum, whereas the rate of increase of income with increase in mechanization shows no slackening. The position of the United Kingdom on the food-graph lies near the maximum, whereas on the income curves it lies well below that of the United States and Canada, though it is high among the European countries. With each additional ton of coal or its equivalent used annually by the individual, the average income rises by approximately £60 a year.

The acceleration in energy consumption is well illustrated by the fact that half the coal used in the history of mankind has been consumed in the past twenty-five years, and half the petroleum in the past ten. Coal had traditionally been used in two ways : to provide energy, and to produce coke for steelmaking—the latter a crude chemical use.

In Great Britain, only two forms of coal consumption are still increasing rapidly : electricity generation by about 80 per cent over the past ten years and metallurgical coke production by about 60 per cent ; other uses are for the most part either falling, stationary, or if still increasing, decelerating rapidly. Coal production is inflexible, the increase over the whole world since 1910 having been only 40 per cent, smaller than the increase in population. Considering the two accelerating demands in this context, electricity production at its present rate of increase cannot for long continue to be based solely on coal ; demand could not be met, and to attempt it would be inimical to the best use of the three main fuels. The nuclear fuels have no other large-scale application, but coal has its considerable chemical value. Moreover, the contribution of fuel to the total cost of manufactured goods is falling. This is due to the general shift from heavy towards light industry in which skill and therefore labour costs are relatively more important. A parallel tendency is from solid fuels towards the more flexible fluid forms, oil and gas. Dr. Bronowski emphasized that, owing to the exhaustion of the older seams and increased mechanization, the trends in the types of coal available are towards the following : coals yielding more volatile matter on heating but of less value in coke making ; an increased proportion of small coal ; and coals of increased ash content. Such lower-grade coals should be regarded progressively, in planning for the future, as raw material for making refined fuels and chemicals rather than as fuels *per se*.

The chemical by-products of coal carbonization now of greatest importance are benzene, naphthalene and phenols; these are linked with gas and coke production. From present tendencies, Dr. Bronowski estimated a need in 1975 for 50 million tons [an estimate perhaps on the high side] of coal to make metallurgical coke, a development that will make available considerably larger amounts of these chemicals. Thus the only use of coal likely to expand considerably will—in opposition to the pattern of production—demand selectively the better classes of coking coal unless the range of coals that can be used for this purpose can be widened—an important research objective. Even with this increase, the production from coal of the three chemicals mentioned will probably be inadequate—barely half the estimated needs of their users. Moreover, the coke oven is a most expensive plant requiring a capital investment of £7·7 for each £1 of value added in the product, as compared with £2·2 average in industry. The remainder of the lecture was therefore concerned with alternative methods of producing chemicals and coke or coke substitutes from a wider range of coals.

The chemical structure of oil is more suited to flexibility in the production of raw materials for chemical industry than that of coal; moreover, research in the past has been pursued more energetically in the oil industry. Nevertheless, the constitution of coal gives it a natural advantage for the production of aromatic chemicals; and though the hydrogen/carbon ratio in coal is low, carbonization leads to disproportionation reactions, yielding volatile products of higher ratio and a carbonaceous residue. Fluid-bed conditions are more favourable to high yields of liquid products than those in the fixed bed of a coke oven, which favour secondary cracking of the products. The former type of process converts coal to a powdered char, with good yields of tar, and a rich gas; these novel tars are less suited to the current market for tar chemicals, though there is a low-price outlet in the expanding market for coal-tar fuels. Dr. Bronowski mentioned the processes, being developed at the National Coal Board's Coal Research Establishment, designed to convert such chars by briquetting to smokeless fuels for domestic use [see also Sir Charles Ellis, *Nature*, **175**, 274; 1955].

Such processes are envisaged only as an interim measure, since the demand for solid smokeless fuels may well prove ephemeral. The next step would be gasification of the char, made as described above by fluidized carbonization with production from the tar of medium oil. The gasification stage could produce alternatively a rich gas for heating or a synthesis gas for production of oil—especially the gas and Diesel oils increasingly in demand as fuels rather than light oil of high octane number, previously the main objective of the Fischer–Tropsch process. Some of the simplest and most flexible chemical raw materials now made from petroleum, such as the olefines, could also then be made as by-products during production of oil from coal. Another potential use for the char is for production of calcium carbide simultaneously with gasification at high temperature using oxygen.

Looking still farther ahead to the end of the century, the possible availability of electricity at very low cost from nuclear reactors might make available cheap electrolytic hydrogen, so that the question of direct hydrogenation of coal to fuel oil, at present uneconomic owing to the high cost of hydrogen and power, might be reopened.

Dr. Bronowski concluded by emphasizing that these were his personal views on the future of coal. In brief, the post-war energy famine is ending; the industrial energy demand will ultimately be carried chiefly by atomic energy; small and high-volatile coal thus set free could be used for making solid smokeless fuels, and later, fluid fuels and chemicals.

In broad perspective, Dr. Bronowski's review of trends and portents corresponds closely with views increasingly coming to be accepted in Britain, and indeed in other European countries (see, for example, D. W. van Krevelen, *Chem. and Indust.*, 546; 1957). It will be conceded that there is likely to be an important shift in the use of coal within a few decades towards gasification and the production of oil. Opinions may differ, however, as to the advantage of a two-stage process, in which fluidized carbonization of coal precedes gasification of the char, over gasification of the coal in a single stage; this will depend partly on the commercial value of the tar produced by the first method. It may also be expected that for many years an appreciable amount of small coal of high ash content will be burnt in boiler plant, increasingly automatic, to provide heat and power for small industries. The extent of this will be affected by the siting of industry: for much of the heat inevitably wasted in a nuclear power station could ultimately be used as process heat in neighbouring factories. A large-scale outlet for higher-grade waste heat might, in fact, be provided by the gasification of coal or char, as suggested especially in the United States; the external source of heat would lead to many economies if it could be provided at not less than 900° C., to maintain an endothermic reaction between carbon and steam. The prospects of success appear, however, to be small (see J. V. Dunworth, "The Future of Nuclear Power", Inst. Gas Eng. Copyright Publ. No. 513; 1957).

One other point should be mentioned: not only is the coke oven, as Dr. Bronowski stated, a most expensive plant; the whole present sequence of steel making, using coke oven, blast furnace and open-hearth furnace, is costly and indirect, since it embodies three major stages and excess carbon introduced in the second has to be removed in the third (though for making special steels retention of this stage in some form would probably be necessary). It is quite possible that a successful single-stage process (see Sir Charles Goodeve, *Advanc. Sci.*, **13**, 23; 1956) might be developed before the end of the century; and if such a process proved effective and economic on an industrial scale it would seem likely that from that time onward only sufficient coke ovens to maintain supplies of foundry coke might be replaced. Their normal life being of the order of twenty years, one must envisage a possibility—no more at present—that the demand for metallurgical coking coals might then fall to a small fraction of its maximum level within some twenty years. Whether this will happen, and when, will determine whether a shortage (other than local) of coking coals is likely to develop, and therefore the importance of research—necessarily in the immediate future—on the production of metallurgical coke from coals at present unsuitable. In the writer's judgment, such research should be continued but regarded as an urgent and possibly short-term activity.

I. G. C. Dryden

SITING OF NUCLEAR POWER STATIONS

IN a debate on the siting of nuclear power stations initiated in the House of Commons on December 19 by Mr. A. Blenkinsop and Mr. T. W. Jones, the Parliamentary Secretary to the Ministry of Power, Mr. D. Renton declined to comment on the project for a nuclear power station in Merioneth because the Minister had already decided to hold an inquiry; but he gave a full account of the procedure for preserving the amenities of the countryside so far as the Ministry of Power is concerned which was distinctly reassuring. Mr. Renton recognized the serious conflict and dilemma which arises, and assured the House that the limited possibilities of using land already developed or waste were not overlooked. In selecting the four sites already chosen and in choosing the remaining eight before the end of 1966, a preliminary general suggestion by the Central Electricity Authority is followed in each case by the search for a particular site by the Authority, and then by application to the Minister of Power, usually with a public inquiry before the Minister gave his decision.

Throughout the three stages there are certain limiting factors. First is the purely economic one, requiring nuclear power stations to be sited where the greatest economic benefit may be secured—in regions where the cost of coal is highest, remote from coalfields. Second are safety considerations, and the Government is adhering to the policy of avoiding built-up areas. Furthermore, such power stations require large quantities of cooling water, as much as 35 million gallons an hour for the stations now contemplated, solid foundations for the very heavy buildings and plant, and an area of about 300 acres.

It is with these considerations in mind that the Central Electricity Board—and from January 1, 1958, the Central Electricity Generating Board—make preliminary studies in each area where a power station appears to be needed. These studies include a thorough consideration of the development plans of local planning authorities, of the maps of the national parks and areas of outstanding natural beauty, both of which must be avoided if possible, and a geographical study of basic physical features, such as water supplies. On the basis of these general studies, the team of technical experts of the Authority proceed to what they call site selection. This may take three to twelve months, involving consideration of every possible site in the area of search and sometimes survey before provisional selection. Besides the local planning authority, the Ministry of Housing and Local Government, the Ministry of Agriculture, the Home Office, the Air Ministry, the Ministry of Transport and Civil Aviation, if necessary the Admiralty and the War Office, the National Parks Commission and the Nature Conservancy are consulted and, after a site has been provisionally selected, the Royal Fine Art Commission. Moreover, Mr. Renton pointed out, under Section 37 of the Electricity Act, the Board, the Electricity Council and the Minister of Power must have regard "to the desirability of preserving natural beauty, of conserving flora, fauna and geological or physiographical features of special interest, and of protecting buildings and other objects of architectural or historical interest".

They must take into account the effect of their proposals on the natural beauty of the countryside and on any such flora, fauna, features, buildings and objects. Furthermore, it is not until these studies and consultations are completed that formal application is made to the Minister for his consent. When the Minister receives such an application he is now obliged to hold a public inquiry whenever a local planning authority objects and he may do so when there is any other objection. In such an inquiry he receives expert advice from his Ministry's inspector, who sometimes sits with an inspector of the Ministry of Housing and Local Government.

Observing that a conflict of public interests could only be resolved by a Minister or Ministers, Mr. Renton said that the aim was to provide a flexible system of planning. Each planning authority had the duty of formulating a county development plan and the Minister of Housing and Local Government has certain statutory duties in respect of development plans. He and other Ministers concerned were consulted by the Minister of Power before he gave his decision on each application, and the Minister's decision, which was that of the Government, could be questioned in Parliament. Mr. Renton said that the Minister of Housing and Local Government had overall responsibility for preserving amenities under the Planning Acts and his Ministry provided the information, maps and detailed plans which helped to prevent any avoidable desecration of the beauties of the countryside. Mr. Renton did not think that the central consultative committee of amenity associations suggested by Mr. Blenkinsop would contribute anything further, and he thought there was already sufficient frequent consultation with the National Parks Commission from the inception of any scheme.

CONCRETE ROADS

AN international congress was held in Rome in October to discuss recent technical progress and achievements in the construction of concrete roads and runways. Seventeen lectures were given by prominent engineers from ten countries and reports on the subjects to be discussed were also received from many others. About 800 delegates from 28 countries attended.

The congress enabled the practice in different countries to be compared, and it was of particular interest to note where there was general agreement and where there were differences. It was generally agreed that motorways and urban expressways were desirable on grounds of economy and safety. Most countries, and in particular Western Germany and Holland which together contain 80 per cent of the motorways existing in Western Europe, have preferred concrete construction for motorways. The slab thicknesses used in most countries were comparable and were based on experience; the thicknesses given were expected to give adequate service; but, when discussing concrete roads other than motorways, there was not complete agreement on the expected life of the road nor on what constituted failure. Probably for this reason there were considerable differences between countries in the change in thickness recommended for different classes of traffic, in the amount of reinforcement and in the spacing of joints. For example, in Belgium reinforcement was not considered necessary for secondary roads, whereas in Britain and Switzerland reinforcement was included in designs for housing estate and rural roads.

Because of the differences in design and in the availability of materials suitable for concrete or for other types of road construction, there were large differences in the views expressed on the economy of concrete construction. In Germany, improvements in bituminous construction resulting in enhanced durability required that there should be qualitative improvements in concrete construction on trunk roads. In Belgium, which has more secondary roads in concrete than elsewhere in Western Europe, this type of construction is claimed to have the advantages of economy in construction and maintenance and of good surface texture. For housing-estate roads in Great Britain concrete roads are considered to be particularly good for carrying builders' traffic, but to require careful supervision during construction if they are to be successful. In Switzerland, concrete roads had proved to be economical for rural roads when maintenance costs were considered as well as the prime cost. The question of the economical design of concrete roads in relation to performance and maintenance costs would obviously repay further study.

Economical design was also considered of major importance for the design of runways capable of carrying the very heavy channelized traffic which was now using heavy-duty airfields. One approach to the problem was to examine the traffic volume on various sections of an airfield and to relate the thickness of the pavement to the load and number of repetitions. If traffic was classified in this way it was possible to make the thickness of mid-sections of runways 25 per cent less than that required at the ends and on the main taxiways. Another approach was to use a prestressed pavement; the construction at Maison Blanche was described and it was estimated that the cost of the 7-in. thick prestressed slab was similar to that of 13 in. of normal concrete. This would correspond to a saving of some 10 per cent since it was considered that for comparable strength a normal pavement would need to be 14½ in. thick.

It seemed to be generally agreed that the subgrade had little effect on the stress in a concrete slab if the soil was uniform and the slab was equally supported over its whole area. In practice, however, uniform support is difficult to obtain, and, compared with twenty years ago, great emphasis is now placed in all countries on the proper compaction of the subgrade and base and, in order to avoid changes in the moisture content of the soil during the life of the road, on the protection of the soil from the weather during construction. In most countries the base thickness considered necessary was greater than that generally recommended in Great Britain; but this difference may be due more to the necessity of providing sufficient thickness of construction to avoid damage by frost than to the requirement for uniform support.

A very valuable summary of the construction practice in different countries was given. There was general agreement on what constituted good practice; but there were differences, many of which were due to the desire for economy. Thus, it was agreed that the concrete should have a high flexural strength and that for this purpose crushed stone aggregates were to be preferred, but gravels were used for reasons of economy. A dense concrete was desirable for durability but plastic concrete was sometimes used for facilitating placing in order to reduce costs. Two-course construction was often employed where cheaper concrete could be used in the lower course. The development of cheaper methods of construction was thus another subject on which a study might be made.

The development of prestressed concrete for roads was discussed. Most experimental work had been done in France and Great Britain but some work had also been carried out in Germany, Switzerland and the United States. It seemed that prestressed slabs of the individual type, that is those stressed by cables, have been preferred in Great Britain and Germany, while prestressed slabs of the continuous type, that is those stressed between abutments, seemed to be preferred in France and Switzerland. It seems probable that where the abutments can be placed a considerable distance apart the continuous method is more likely to be economical, but the problem of maintaining stability against buckling and of dealing with horizontal curves needs more consideration. With the individual type of slab the major problem is concerned with joints. With both types the question of reducing subgrade friction is also of importance. The congress felt, however, that the development of prestressed concrete for roads was of great importance because of the economies it appeared likely to achieve.

Finally, there were two papers on the surface irregularity of concrete roads. The methods of measuring the evenness were different, and a plea was made for agreement on an accepted international method so that comparisons could be made easily. Although a direct comparison could not be made, examination of the two papers suggested that the riding quality of recent Danish and recent British work was of the same order of quality but that considerably more effort was required in Britain to achieve that standard. In this connexion, however, it seems probable that the differences in the methods of construction may have some effect on the ease with which good riding quality may be obtained. For example, the Danish roads are generally unreinforced while reinforcement is generally included in British roads. The rate of progress during construction would therefore normally be slower in Britain, thus making the achievement of an even surface more difficult. It is important to remember, however, that the comparison is generally made between new roads, and it appeared from the discussion that the differences in construction might lead to differences in performance so that after some years under traffic the ultimate riding quality of roads of the two designs might be different. Further information is obviously desirable about the movements of slabs under traffic.

The congress thus enabled the present practice and experience in different countries to be compared. Although there was agreement on many points it was considered that further meetings to exchange experience, with perhaps a more limited field, would be of considerable value, particularly where new developments such as prestressed concrete were concerned.

R. H. H. Kirkham

LIVING CONDITIONS AND HEALTH

A MEDICAL conference on "The Influence of Living and Working Conditions upon Health" was held at Cannes during September 27–29, under the chairmanship of Prof. J. Parisot, former president of the World Health Assembly, and Prof. J. de Castro, formerly president of the United Nations Food and Agriculture Organization. The French Ministry of Health and Atomic Energy Commission were represented.

In the section on nutrition the diverse ways in which food factors operate were discussed on a world level by de Castro, while Cicely Williams laid stress on the social factors that might often exceed the physiological in a given food situation. According to Yang-En-Fu, recent examination of the high cereal diet common in China had shown evidence of reasonable adequacy of its vegetable protein with consequently less necessity for substitution by meat; local vegetable foods, fortified by vitamins and minerals, could be expected to correct the main deficiencies of this diet.

D'Arcy Hart considered that the highly efficient chemotherapy now available against tuberculosis imposes some re-thinking on nutritional policy in relation to this disease in under-developed countries. It is imperative to discover whether such chemotherapy is effective in the malnourished, so that mass chemotherapy can be integrated with general social and nutritional improvements; probably host resistance to infection remains important for healing, however potent the drugs may be in the initial stages of treatment. Techniques and factors, particularly psychological, in the study of fatigue in industry were discussed by Desoille and Le Guillant in the section on work factors, while problems of industrial disease in various occupations were presented by other speakers. These include Reysek, who told of some apparently new types of pulmonary exercises being tried in Czechoslovakia for silicotics, which were suggested by observations on glass blowers.

The third main topic on late effects of ionic radiations was introduced by Lacassagne, who concluded that collective measures, which would restrict the almost inevitable increase in the chance of the total population being exposed to a supplementary dose of such radiations, should not be delayed. The results of a follow-up in 1956 on the changes in blood and bone marrow in survivors of Hiroshima were given by Kono, who said that, apart from leukæmia, significant abnormalities were found on close examination of some apparently normal persons. Peacock pointed out the possible future carcinogenic dangers from radioactive isotopes. The general view of the speakers seemed to be that practice had outrun experiment and safety tests.

The conference concluded by forming an "International Medical Association for the Study of Health and Living Conditions"*, which, it is assumed, will sponsor the recently published journal *Living Conditions and Health*, the first two numbers of which have appeared in no less than six languages.

IMMUNITY IN PARASITISM

"THE Nature of Immune Responses in Parasitism" was the subject discussed at a meeting of the Parasitology Group, Institute of Biology, on October 18, at 41 Queen's Gate, London, S.W.7. Three speakers were invited to read papers.

Dr. M. Robertson (Lister Institute) summarized the results of the investigation into the antibody response of cows and heifers to infection with *Trichomonas foetus*. This work was carried out in collaboration with Dr. W. R. Kerr, of the Ministry of Agriculture, Northern Ireland.

The parasite develops in the uterus, and antigen, probably from the breakdown of the trichomonads, passes into the lymph glands and blood stream, resulting in the production of circulating agglutinins. The antibody in the blood stream has no protective value as it does not come into contact with the trichomonads at the site of infection.

The presence of *T. foetus* in the uterus stimulates the local production of antibody, which in acute cases of the disease appears to have a brief protective value in early re-exposure to infection.

Antigen passes out from the uterus, and antibody is produced in the circulating blood; but antibody does not pass back from the blood into the uterus. Trichomonads from the uterus appear in the vagina, sometimes in great numbers. Their presence stimulates the appearance of antibody in the vaginal mucin which causes the temporary disappearance of the trichomonads from the vagina, but does not have any value in protecting the animal from re-infection.

The vaginal antibody is probably produced locally. It is of great diagnostic value.

The antibody reactions of the rat to infection with *Trypanosoma lewisi* were briefly described. The trypanocidal antibody and the growth- and division-controlling antibody, or ablastin, studied by Taliaferro were referred to, and further work on the nature of ablastin was mentioned.

Dr. E. J. L. Soulsby (Cambridge) presented work concerned with immunological responses of the host to helminth infestations.

The way in which immune mechanisms may modify naturally ocurring helminth infestations was briefly indicated, with particular references to gastro-intestinal nematodes of sheep. It was shown that the degree of immunity of the host, as measured by antibody-levels, was inversely proportional to the intensity of infestation and to the level of egg production. An almost complete elimination of previously high infestations occurred in early summer, and this was associated with a marked immunological response by the host. Following the elimination of the helminths, a period of protection was established in the sheep despite persistent reinfestation.

More detailed work with *Ascaris lumbricoides* in the guinea pig showed that a marked immunity to re-infestation can be induced by administering infective stages orally or by alternative routes. With the exception of the 'metabolic products' of third-stage larvæ, non-viable worm material induced no protective immunity in the guinea pig. The critical period for the release of helminth antigen, which ultimately induces protective immunity, appears to be from four to six days after infestation. The earlier larval stages appear to be unimportant in stimulating immunity. During the period of four to six days after infection the second-stage larvæ moult, but in an immune host the growth of the larvæ is inhibited and they do not reach the size at which moulting normally occurs. Using a natural marker antibody (Forssman antibody), it was found that the period between the fourth and fifth days after infection was the earliest time at which a marked release of antigen could be expected. Since this period coincides with the commencement of moulting, the moulting process is strongly suspected as an important mechanism for the release of antigens which stimulate protective immunity in the host.

Dr. K. Mellanby (Rothamsted Experimental Station) spoke at short notice, in place of Prof. R. M. Gordon, on reactions to insect bites and infestation by mites and ticks.

Individual animals respond differently to the bites of particular insects, and the responses change with the period and intensity of the attack. Two and possibly three antigens may be involved. The first evokes a weal 5–10 min. after exposure. The second antigen produces the delayed, tuberculin-type reaction some hours after exposure. Thirdly, there may be a more serious, generalized reaction, distinct from the delayed reaction and possibly related to a third antigen. The antigens are injected with the saliva of the biting insects, but also occur in their tissues. Thus, extracts of larval, pupal and male mosquitoes may give similar reactions to the bites of adult females. Reactions to non-biting insects (for example, sensitization to locusts) are essentially similar to reactions to bites.

A previously unexposed person may not react to a first bite. However, after exposure he shows the immediate reaction to a bite, and on further exposure shows the delayed reaction as well. Generally, further exposure causes the delayed reaction to disappear, and prolonged exposure may eliminate the immediate reaction also.

The reaction of the host does not affect the feeding of most blood-sucking insects, but the feeding of mites and ticks, which may take some days to engorge, may be interrupted in sensitized hosts by the infiltration of leucocytes around the mouth-parts. Sensitization to the scabies mite *Sarcoptes* causes local œdema and the mites tend to leave their burrows; the sensitized individual may be virtually immune to scabies.

Other workers have reported differences in the reaction to bites of clean insects and those infected with parasitic diseases. In the rickettsial disease, scrub typhus, infecting bites may give characteristic local lesions not caused by uninfected mites.

June Mahon

INTERNATIONAL SCIENTIFIC RADIO UNION

The twelfth general assembly of the International Scientific Radio Union was held at Boulder, Colorado, during August 22–September 5 and was attended by more than 550 delegates and observers from twenty-seven countries. The meetings of the full assembly and of the executive and organization committees were held under the chairmanship of Father P. Lejoy, who was serving a second term as president of the Union. This was the first assembly since the recently constituted national committees in Austria, Greece and the U.S.S.R. had been formed; delegates from these countries were warmly welcomed, and they took an active part in the scientific work of all the meetings in Boulder.

As is probably now well known, the main functions of the Union are to promote and organize radio research requiring international co-operation and to encourage the setting-up of such common methods of measurement as may be required for the study of any radio phenomena, whether or not these be directly associated with the Earth and its atmosphere. The work is carried out by seven commissions, each of which is concerned with specific aspects of radio research, and ranging from measurements and standards, and the use of circuits and electronics techniques to all aspects of wave propagation, and terrestrial or atmospheric noise and the important new developments in radio astronomy.

Detailed accounts of the work of each commission will be published in due course in the "Proceedings of the General Assembly". In the meantime, the results of this work are crystallized in the resolutions which each commission made and presented to the assembly for adoption. These resolutions are being printed in the Information Bulletin of the Union, which is published by the Secretary-General at 7, place Emile Danco, Uccle-Brussels (Belgium). The most recently issued Bulletin—No. 105—contains the recommendations and resolutions of Commissions 1, 2, 5 and 6, and those of the remainder will presumably be in a later issue. A list of the commissions, with their officers and the national official members, is also given in the same Bulletin.

Prior to the general assembly in Boulder, meetings were held in New York of the Mixed Commission on the Ionosphere under the chairmanship of Sir Edward Appleton, and of the Joint Commission on Radio-meteorology with Dr. W. E. Gordon as chairman. The work of these groups is conducted in close co-operation with the corresponding commissions of the International Scientific Radio Union, namely 3, "Ionospheric Radio" and "Radio and Troposphere", of which Drs. D. F. Martyn and R. L. Smith-Rose, respectively, were re-elected chairmen.

At the closing meeting, Dr. L. V. Berkner was elected president, and it was decided that the next general assembly would be held in the United Kingdom in 1960. A revised scale of national subscriptions was introduced, and provision was made for the organization between general assemblies of international symposia on specialized subjects relating to radio scientific matters.

PHYTOCHEMISTRY

SPONSORED jointly by the Government of the Federation of Malaya and Unesco, a symposium on phytochemistry was held in the new Government chemical laboratories at Petaling Jaya, Kuala Lumpur, during December 4–8. The symposium, under the chairmanship of Prof. R. A. Robinson, was attended by sixteen overseas visitors, together with eighteen scientists representing the University, Government departments and research institutions in Malaya and Singapore.

The symposium was opened on Wednesday morning by the Hon. the Minister of Health, Mr. V. T. Sambanthan, and by the Unesco representative, Mr. Lennart Mattsson, both of whom emphasized that this was the first occasion since Malaya had achieved independence that a meeting of scientists including overseas delegates had been held in this territory and that in view of this region's dependence on plant products it was particularly appropriate that the first symposium should concern itself with phytochemistry.

Twelve original papers were presented to the symposium: "Avicennin, a new coumarin from *Zanthoxylum avicennae*", by Dr. H. R. Arthur (Hong Kong); "Constituents of *Phebalium nudum*", by Prof. L. H. Briggs (New Zealand); "Alkaloids of Apocynaceous Plants", by Dr. A. Chatterjee (India); "Preliminary Investigations on the C.N.S. Action of Indonesian *Rauwolfia* spp.", by Prof. A. J. Darman (Indonesia); "The Occurrence of some Optically Active Compounds in Anacardiaceous Exudates", by Dr. H. H. Hatt (Australia); "Testing for Anti-Arrhythmic Action of New Compounds in Dogs with Ventricular Tachycardia", by Prof. A. S. Harris (United States); "Chemical Constituents of the Plants of Coniferae and Allied Orders", by Prof. T. Kariyone (Japan); "The Isolation and Separation of Alkaloids of *Kopsia singapurensis*", by Dr. Kiang and Mr. R. D. Amarasingham (Singapore); "Recent Advances in Tea Chemistry in Japan", by Dr. Y. Sakato (Japan); "Bis-coclaurine Alkaloids from *Phaeanthus ebracteolatus*, with special reference to Phaeantharine", by Prof. A. C. Santos (Philippines); "Experimental Research on the Toxicity of Rice infected by *Penicillium citrinum*", by MM. Tran-Vy, Truong-Van-Chom and Bui-Duy-Tam (Vietnam); and "Preliminary Investigations on the Separation of Alkaloids of *Rauwolfia perakensis*", by Mr. Wan Sai Cheong and Dr. A. K. Kiang.

Surveys were presented by delegates from Australia, Hong Kong, India, Indonesia, Japan, Malaya, New Zealand, the Philippines and Vietnam describing the phytochemical work already done in their areas and outlining their future programmes. These surveys were integrated with round-table discussions of the problems associated with the collection of plants and their dispatch from field to laboratory, the chemical and biological methods used in the screening of plants for useful products and the exchange of further information between delegates on return to their own countries. The desirability of depositing specimens in recognized herbaria was stressed and the meeting expressed the opinion that in all publications from this region the herbarium number should be quoted. Unesco was asked to publish the proceedings and also to issue from its regional office in Djakarta a periodical newsletter containing items of phytochemical interest.

R. A. ROBINSON

THE SHIRLEY INSTITUTE

THE thirty-eighth annual general meeting of the British Cotton Industry Research Association was held at the Shirley Institute, Manchester, on October 10, with the chairman of the Association presiding. In his address, Mr. N. G. McCulloch said that he believed that the Institute could be of immense service to higher management in the field of operational, as well as technological, research. The chairman was also convinced that some kind of common policy among the directors of the 2,000 firms in the industry was essential if it were to be in a position to compete successfully in the European Free Trade area. He was very happy to be able to report considerable progress in the matter of the co-ordination of research with the British Rayon Research Association, and also to announce a generous offer by the British Man-made Fibres Producers' Committee which, subject to equal support being obtained from the industrial rayon users, would assist materially in financing the Association's work. Mr. J. Lindley, honorary treasurer, in reviewing the statement of accounts for the year, reported that although the new terms of the Government's grant-in-aid were potentially more generous, there would have to be a considerable increase in the industrial income, if the Association's funds were to achieve the full benefit.

Dr. D. W. Hill, director of research, then presented his report on the year's work which once again had shown intense activity in all branches of the Institute's activities. In selecting a few of the recent developments for comment, Dr. Hill mentioned the great success of the dust hood, now re-named the Shirley pressure point system for dust extraction, in ridding the industry of byssinosis, an occupational disease of the card room for more than 100 years. The director also referred to the complete success in prolonged mill trials of the Shirley separator for hard waste breaking-up machines, a simple and inexpensive device which could be fitted to existing machines to separate out the harder waste which could then afterwards be reprocessed. The dry feed system for the automatic size box had been further developed to give precision and accuracy, and a new automatic size box was also being developed to deal with all types of continuous filament yarns. The Shirley loom for high quality fabrics, the prototype of which had been undergoing prolonged mill trials, was now working satisfactorily. The comprehensive programme of fibre blending was yielding results which were becoming rapidly available to members. Dr. Hill also made special mention of the work on flame-proofing, the new rapid ager for colloresine printing, the intensive survey of industrial mangling, and the bulked yarn programme. He pointed out further that in spite of petrol rationing, the Institute had had almost 11,500 technical transactions with its members (against 12,000 in the previous year) including 2,999 special visits, figures which, he thought, would be of interest to those who suggested that the industry was not sufficiently interested in technical advance.

As in previous years, the Institute's laboratories were open for inspection for two days with senior members of staff available for consultation. For condenser spinners the hard waste breaking-up machine was displayed. Much of the emphasis in the spinning section was on a number of simple devices for improving quality control in the mill. Much of the fundamental work on spinning has been devoted to the preliminary stage of a programme of research with the immediate emphasis on automatic regularity control at several stages of the process.

Weavers were shown a new dobby which has been incorporated in the Shirley loom. Two sizing innovations which attracted interest were the recent developments of the automatic size box, the principle of which has now found application outside textiles.

The work on raising carried out in the Finishing Department provided a display of important information on power consumption and on the effect on the rate of raising of variations in the cloth speed. The exhibition which attracted most attention from finishers, however, was the new flash-ager, for accelerating, and in some instances improving, the development of colloresine printing. Work on industrial mangles, which is almost complete, has led to the production of an improved liquid removal process, in addition to providing data from which target figures at which to aim in plant operation can be given.

Fundamental chemical work was represented by four exhibits. Infra-red spectroscopic equipment was being utilized for investigating chemically modified cellulose; the results were shown of a critical examination of the effects of cyanoethylation on cotton; the interactions of formaldehyde with cellulose and of formaldehyde with urea are being investigated and some results were illustrated which, in addition to being of considerable chemical interest, will advance the understanding of the increasingly varied resin-treatment of textiles; and the partition chromatographic techniques which have considerably advanced knowledge of the structure of silk fibroin were demonstrated.

The Institute continues its fundamental investigations of the effect on yarn properties of blends of fibres (particularly of man-made with natural fibres) in various proportions in the yarn; work in three departments was displayed including the results of chemical treatment of various blends; another working exhibit was of the equipment for producing tailor-made synthetic filaments, the physical properties of which can be related to the chemical properties of the parent polymer.

There is a newly constituted department concerned solely with members' problems either of quality control or arising from the introduction of new fibres and processes in the mill and works. The department is staffed with physicists and chemists and textile technologists, and examples were shown of the use of spectroscopy in diagnosing biological damage, of the photochemical properties of certain new dyes and of the solution of some of the difficulties most frequently posed by members.

It is not the concern of the Institute to search for new textile products, but inevitably there are occasions when such materials are discovered during some broader research. On this occasion two such discoveries were displayed, namely, an elastic yarn made by a new process and a metallized fabric with novel optical properties. These aroused considerable interest.

Lastly, mention must be made of the continuing work on instruments for quality control which has had so great an impact on the industry in recent years, particularly since the setting-up of Shirley Developments Limited. The Company had its own display of instruments which it handles, and, in addition, there were four new instruments developed at the Institute which will shortly be handed over for exploitation.

The occasion of the annual general meeting and its two associated members' days was successful in attracting a total attendance of 800, representing 217 firms.

INFLUENCE OF ORGANIC VAPOURS ON THE CRYSTAL HABIT OF ICE

By J. HALLETT and Dr. B. J. MASON

Department of Meteorology, Imperial College of Science and Technology, London, S.W.7

ICE crystals grown from the vapour, both in atmospheric and in laboratory supercooled clouds, show the following remarkable variation of habit with temperature[1]: 0° C. to − 3° C., thin hexagonal plates; − 3° C. to − 8° C., needles and hollow hexagonal prisms; − 8° C. to − 25° C., plates; stellar dendrites around − 15° C.; < − 25° C., prisms.

Experiments by Shaw and Mason[2], in which crystals were grown on a metal surface under conditions in which the temperature and supersaturation of the surrounding atmosphere could be varied independently, showed that the crystal habit was determined by the temperature according to the above scheme and that variation of the supersaturation produced no systematic effects. More recent experiments[3] in which crystals are grown on a fibre suspended in the centre of a water-vapour diffusion chamber confirm this result. The habit of crystals growing along the length of the fibre, over which the temperature varies from 0° C. to − 50° C., again changes in accordance with the above scheme with dendritic crystals being limited to the temperature-range − 12° C. to − 16° C. and appearing only if the supersaturation exceeds about 10 per cent. Variation of the supersaturation over very wide limits (0–300 per cent) does not induce changes as between the essential prism and plate-like habits, but such transitions may be induced by varying the temperature by only one degree centigrade.

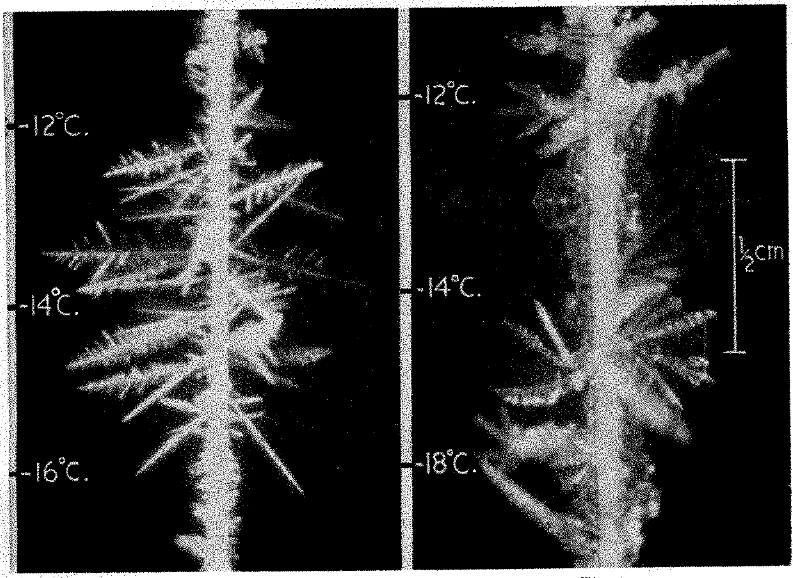

Fig. 1 Fig. 2

The variation, at about − 14° C., of ice-crystal habit with increasing concentrations of *iso*-butyl alcohol. Fig. 1. Dendritic growth; no alcohol present. Fig. 2. Plate-like growth; vapour pressure of alcohol 10^{-3} mb.

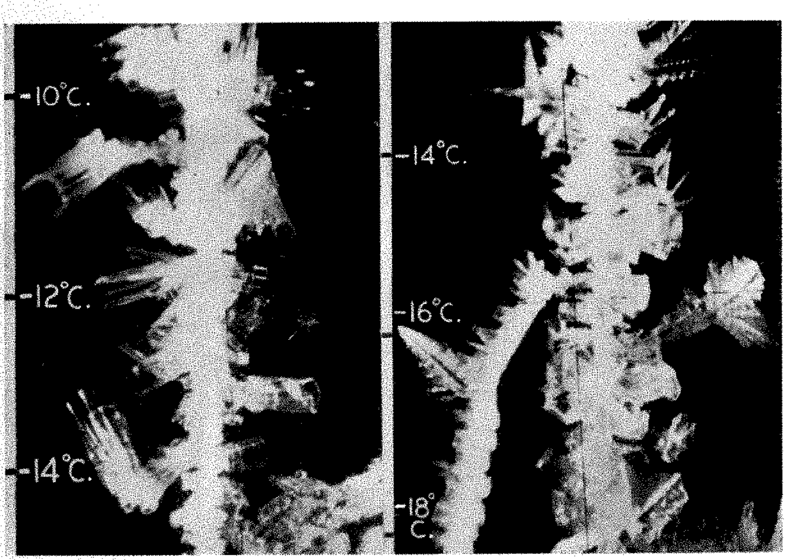

Fig. 3 Fig. 4

The variation, at about − 14° C., of ice-crystal habit with increasing concentrations of *iso*-butyl alcohol. Fig. 3. Hollow prisms; alcohol pressure 10^{-2} mb. Fig. 4. Reversion to dendritic growth; alcohol pressure 1 mb.

Nakaya[4] has reported that the growth forms of ice crystals may be modified by the presence of atmospheric aerosols. For example, he states that when the air is filtered to remove the suspended particles, the plate and dendritic crystals which normally occur at about − 15° C. are replaced by hollow prisms. We are unable to confirm this result. Crystals growing in our diffusion chamber show exactly the same variation of habit with respect to temperature irrespective of whether they grow in the presence of a water cloud formed by condensation on atmospheric aerosol particles or in very clean air from which all the particles have been removed by sedimentation.

However, it has been found that the presence of traces of organic vapours may profoundly influence the growth habit of ice crystals. For example, crystals grown in a diffusion chamber in which *iso*-butyl alcohol has been added to the water source show remarkable changes of shape as the concentration of alcohol vapour is varied from 0 to 1 mb. partial pressure. The vapour density of the alcohol, which diffuses downwards into the colder regions of the chamber in much the same way as the water vapour, can be estimated at each level by specifying its values at the source and sink and assuming a linear gradient in between. The concentration of alcohol vapour at the top of the chamber (the source), which is varied by changing the alcohol–water ratio of the mixture by successive factors of ten, is determined in terms of the partial pressures of the two component liquids. The vapour pressure of the alcohol at the sink, which is at − 50° C., is assumed to be practically zero. Although, in view of the simplifying assumptions, the calculated values for the absolute concentration of alcohol at each level may be slightly in error, the relative concentrations at different levels are probably reliable.

The most striking variations of crystal habit with increasing concentrations of alcohol occur between − 12° C. and − 16° C.; these are shown in Table 1 and illustrated in Figs. 1–4. When the partial pressure of the alcohol exceeds about 10^{-3} mb. the normal dendritic growth (Fig. 1) is suppressed and replaced by plate-like crystals (Fig. 2). A further rather small increase in alcohol concentration causes these to be replaced, either by hollow prisms or by needles (Fig. 3), which persist until the concentration is raised beyond 0·1 mb., above which there is a further transition to plates, and finally, at higher concentrations still, a reversion to a rather stunted form of dendritic growth (Fig. 4).

An earlier observation by Vonnegut[5], that a cloud of tiny hexagonal plate-like crystals, growing at

Table 1

Dendrites				
	Plates			
		Hollow prisms and needles		
				Dendrites

– 20° C., was transformed into hexagonal prisms by the addition of butyl alcohol at a partial pressure of about 10^{-2} mb. is confirmed. A reversion to plates occurs if the concentration of butyl alcohol exceeds about 0·2 mb. Similar transitions are also observed in the temperature-range – 8° C. to – 12° C.

The mechanism by which such sharp changes in crystal habit are produced either by small changes of temperature or by the adsorption of small quantities of certain organic vapours is not fully understood. However, experiments suggest that the habit changes, which reflect changes in the relative growth-rates of the basal and prism faces of the crystals, are due primarily to changes in surface structure, which is likely to be profoundly affected by the adsorption of foreign polar molecules, possibly by the poisoning of dislocation sites.

ESTIMATION OF ELECTRON AFFINITIES OF OXYGEN BY EXTRAPOLATIONS OF IONIZATION POTENTIALS

By DR. D. F. C. MORRIS
Department of Chemistry, Brunel College of Technology, London, W.3
AND
H. N. SCHMEISING
Department of Chemistry, Queen Mary College, London, E.1

EXPERIMENTAL determinations of the first electron affinity of atomic oxygen, $E(O \rightarrow O^-)$, have given results in unresolved conflict. A relatively short time ago a value in the range 2·0–2·33 eV. was suggested by studies of electron attachment at a hot filament and from dissociative attachment in a mass spectrometer[1]. (Data expressed in eV. should be multiplied by the factor 23·05 to obtain corresponding values in kcal./gm.-atom.) More recently, Smith and Branscomb[2] obtained the value 1·48 eV. by observing the threshold and measuring the cross-section for photo-detachment of an electron from the O^- ion. Also, Schüler and Bingel[3] have derived the values 0·98 and 1·05 eV. from spectroscopic studies. There is thus considerable uncertainty as to the correct value of the electron affinity.

In addition to experimental methods, various theoretical and semi-empirical procedures have been employed to derive electron affinities[4], and the whole problem has been reviewed by Pritchard[5]. One of the most widely used of the various extrapolation methods for the estimation of electron affinities of atoms depends on a knowledge of the ionization potentials of a series of isoelectronic ions. This type of method is considered here in connexion with the estimation of the first and second electron affinities of atomic oxygen. An indication of the consistency of the results may be obtained by comparing the sum of these electron affinities with the affinity of oxygen for two electrons, which may be evaluated by employing the theoretically calculated lattice energies of oxides in conjunction with known thermodynamic data[6,7].

Table 1. IONIZATION POTENTIALS OF IONS ISOELECTRONIC WITH O^- AND THE FIRST ELECTRON AFFINITY OF OXYGEN

Z	Ion	Ionization potential I			
		Moore	Finkelnburg and Humbach	This work	Selected value
9	F	17·42	17·418		17·418
10	Ne^+	41·07	41·07		41·07
11	Na^{2+}	71·65	71·8 ± 0·1*	71·715*	71·715
12	Mg^{3+}	109·29	109·3		109·29
13	Al^{4+}	153·77	153·8		153·77
14	Si^{5+}	205·11	205·1		205·11
15	P^{6+}	263·31	263·3		263·31
16	S^{7+}	328·80	328·4 ± 0·1*	328·6*	328·6

Extrapolation to $Z = 8$ gives $E(O \rightarrow O^-) = 1·044$ eV.
* Interpolated values.

Table 2. IONIZATION POTENTIALS OF IONS ISOELECTRONIC WITH O^{2-} AND THE SECOND ELECTRON AFFINITY OF OXYGEN

Z	Ion	Ionization potential I			
		Moore	Finkelnburg and Humbach	This work	Selected value
9	F^-				3·577*
10	Ne	21·559	21·559		21·559
11	Na^+	47·29	47·29		47·29
12	Mg^{2+}	80·12	78·2 ± 0·1†	80·14†	80·18‡
13	Al^{3+}	119·96	119·96		119·96
14	Si^{4+}	166·73	166·73		166·73
15	P^{5+}	220·414	220·41		220·41
16	S^{6+}	280·99	280·99		280·99

Extrapolation to $Z = 8$ gives $E(O^- \rightarrow O^{2-})$ equals – 7·754 eV.
* Value selected by Pritchard (ref. 5).
† Interpolated values.
‡ If this term were omitted, and extrapolation carried out, the same result would be obtained for $E(O^- \rightarrow O^{2-})$, namely, – 7·754 eV.

Although the ionization potentials, I, of isoelectronic ions are the eigenvalues of a discontinuous function of the atomic number Z, the present work is based on the premise that they satisfy a continuous well-behaved function.

The best way of finding whether the table of a function is reliable is to form a table of successive differences. The onset of 'noise' in the table indicates to how many significant figures the tabulated function is reliable. The most recent set of ionization potential data for ions isoelectronic with O^- and O^{2-} appears to be that of Finkelnburg and Humbach[8]; the values together with those given by Moore[9] are listed in Tables 1 and 2. The data of Finkelnburg and Humbach in Table 1 fit a well-behaved function quite reasonably. Their data in Table 2, however, do not represent a well-behaved function, as is indicated by the early onset of 'noise' in a difference table.

Following the initial premise that the ionization potentials should satisfy a well-behaved function, the interpolated values of Finkelnburg and Humbach have been recomputed by means of the Lagrange formula:

$$f(x) = \sum \frac{\prod\limits_{i \neq j}^{n} (x - x_i)}{\prod\limits_{i \neq j}^{n} (x_j - x_i)} . f(x_j) \qquad (1)$$

This may be rewritten as

$$f(x) = \sum_j L_j f(x_j) \qquad (2)$$

L being referred to as the Lagrange coefficient of the *j*th term. The results of the interpolations are given in column 5 of Tables 1 and 2. Although the best fit would be obtained by the use of Tchebychev coefficients, it was decided that the reliability of the data did not merit the extra work involved. (An extrapolation using weighted data may therefore be merited, but this was not done since it is uncertain which of the higher terms are most reliable.) The calculations have been performed on an electronic digital computer, the Lagrange programme being used for performing the final extrapolation to $Z = 8$.

The extrapolated value corresponding to the first electron affinity of oxygen was found to be 1·044 eV. This agrees well with the experimental results of Schüler and Bingel[3], namely, 1·05 and 0·98 eV.

The extrapolation required to obtain the second electron affinity of oxygen $E(\mathrm{O}^- \rightarrow \mathrm{O}^{2-})$ provides more difficulty. Morris[7] has recently derived the value − 6·63 eV. for the double electron affinity of oxygen $E(\mathrm{O} \rightarrow \mathrm{O}^{2-})$ from lattice-energy calculations, and it appears reasonable to regard this value as correct to within ± 0·3 eV. It follows that $E(\mathrm{O}^- \rightarrow \mathrm{O}^{2-})$ should be about − 7·67 eV. This may be compared with the value − 7·754 eV. obtained by extrapolating the selected values in Table 2. To assess the variation of $E(\mathrm{O} \rightarrow \mathrm{O}^{2-})$ on altering I_{12} in Table 2, it is necessary merely to evaluate L_{12}. This is − 17·5. Hence, if values for I_{12} of 80·12 or 80·14 eV. are adopted, I_8 is increased by 1·05 or 0·7 eV., respectively, and $E(\mathrm{O} \rightarrow \mathrm{O}^{2-})$ equals − 5·66 or − 6·01 eV. On the other hand, if the value of $I_{12} = 80{\cdot}2$ eV., quoted in Landolt-Börnstein[10], is taken, $E(\mathrm{O} \rightarrow \mathrm{O}^{2-})$ equals − 7·06 eV. The introduction of the value 80·12, 80·18 or 80·20 eV. into the difference table gives rise to considerable noise. It follows, if our major premise is to hold, that at least one *other* of the selected values in Table 2 is suspect. However, in view of the fact that the Lagrange coefficients of the middle terms are quite large, only small adjustments to these terms, about 0·02 eV., would be required to make the data satisfy a continuous function consistent with $E(\mathrm{O}^- \rightarrow \mathrm{O}^{2-})$ equal to −7·754 eV.

From the preceding argument it follows that the value for $E(\mathrm{O} \rightarrow \mathrm{O}^{2-})$ obtained by extrapolations of ionization potential values of present known accuracy, − 6·71 eV., is consistent with the value, − 6·63 eV., obtained from lattice energy calculations.

Our thanks are due to Dr. P. N. Daykin and Dr. A. J. Carr for helpful and stimulating discussion.

MAMMALIAN CELLULOSE

By DR. D. A. HALL, DR. P. F. LLOYD* and H. SAXL
Nuffield Gerontological Research Unit, Medical School, University of Leeds
AND
DR. F. HAPPEY
Textile Department, Bradford Institute of Technology

IT has been shown recently that following treatment with alkaline buffers collagenous tissue contains domains in which masses of 'elastica staining material' can be observed[1,2]. Further work has shown that numerous fibres or lamellæ with a high degree of birefringence may be associated with these domains, and their presence is more clearly seen after alkali treatment of the collagen and ground substance. Such fibrous systems have now been identified as minor components of many adult human tissues, but from present observations appear rarely in infant tissue. There is also evidence that they may constitute a significant component of certain pathological tissues, for example, dermis from cases of scleroderma. Hence it is felt that the presence of these adventitious fibre species in quantity may indicate aberrant developments in the metabolism of connective tissue. Thus a study of these fibres has been made using both chemical and physical methods.

The fibres are of two types, illustrated in Figs. 1 and 2. (These illustrations show two fibres obtained from fresh bovine skin by treatment with alkali, followed by digestion with collagenase and elastase, boiling with 2 per cent acetic acid and treatment with saturated lithium bromide solution to remove residues of keratin. Dried, unfixed preparations.) The first demonstrates uniform anisotropy in all directions. Hence there is no extinction of birefringence, whether the fibre is arranged parallel or at right angles to the plane of polarization. Extinction does occur, however, if the fibre is rotated about its axis (Fig. 1). The other group of fibres (Fig. 2) is

---

* Present address: Department of Chemistry, University College of North Wales, Bangor, N. Wales.

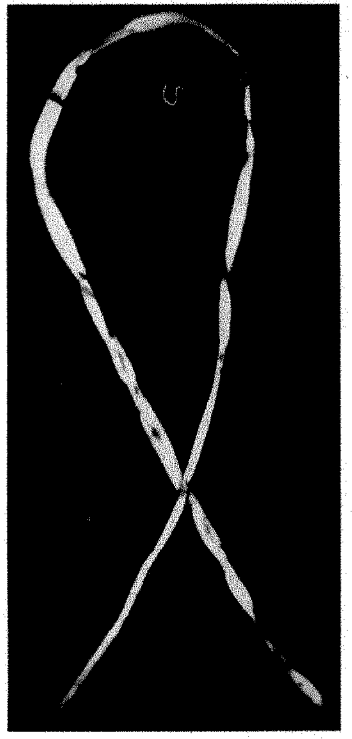

Fig. 1. Anisotropic fibre photographed in monochromatic sodium light. The birefringence is not associated with the orientation of smaller anisotropic rods, since it is not extinguished where the fibre is curved. Examined in white light the fibre shows very little dichroism in some regions. With a first-order red plate it is negatively birefringent like cellulose, and the refractive index is also of the same order as cellulose. (× 141)

characterized by the presence of either one or two anisotropic helices wound around a core, which shows little or no birefringence.

Preparations of small quantities of fibres in a relatively pure state have been obtained by the removal of the surrounding tissue by reaction with collagenase, elastase, boiling 2 per cent acetic acid and treatment with reagents specific for the fission of hydrogen bonds, such as lithium bromide. There was no evidence that these reagents had any effect on the completely anisotropic fibres, but lithium bromide treatment of those which consisted of two clearly observable phases (the polysaccharide did not form a complete pellicle around the ground substance) caused a certain amount of swelling, accompanied by the uncoiling of part of the outer helical layer (Fig. 2).

Hydrolysates of fibre preparations showed the presence of both amino-acids and sugars. Chromatography of the hydrolysates indicated that the protein portion of the fibres had an amino-acid composition intermediate between that of collagen and elastin. The polysaccharide portion, on the other hand, consisted in the main of glucose, associated with small amounts of pentoses and amino-sugars which could be derived from mucopolysaccharides. This high concentration of glucose coupled with the solubility properties of the intact fibres suggested that the polysaccharide might well be cellulose, or some related polymer.

Optical measurements on the fibres between crossed nicols gave the refractive indices with the fibre axis parallel and at right angles to the plane of polarization of 1·586 and 1·525, respectively. The

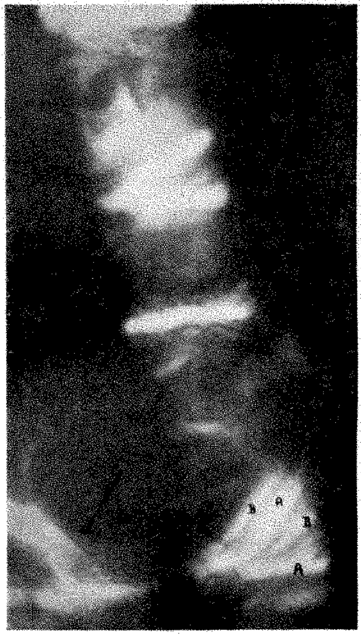

Fig. 2. Fibre composed of two phases: a core oriented in one direction only, and an outer layer having helical orientation. Observations in white light indicated dichroism of the core in some regions but none in the helix, and on examination with a first-order red plate only the helix had a yellow coloration and thereby the two phases could be separated. The outer helix is much more highly oriented, being of the same order as cellulose. Some of its layers have been stripped off (shown by arrow) and two superimposed layers of the anisotropic helices (*AA*, outer layer; *BB*, inner layer) can be seen. Photographed in white light. (× 1215)

sign of this birefringence is negative, and its value, 0·061, lies close to that of ramie. X-ray examination of the fibres confirmed the presence of native cellulose (Fig. 3). Finally, infra-red spectra, although rather complex and difficult to interpret due to the simultaneous presence of both polysaccharide and protein, were not inconsistent with the above conclusions.

Microscopic examination of the angles of the helices of those fibres with a partially developed polysaccharide phase (as in Fig. 2) showed a spread about

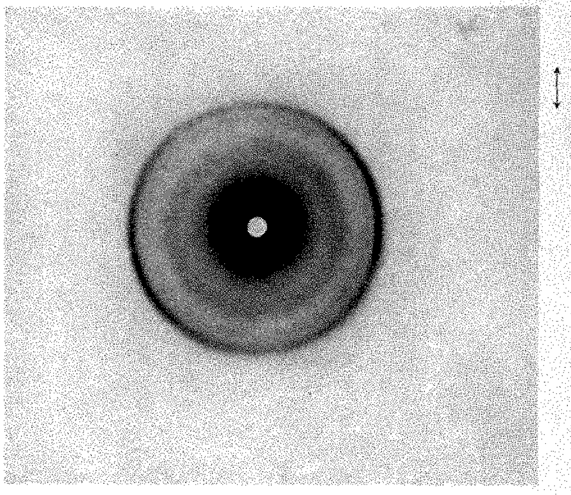

Fig. 3. X-ray diagram of aligned fibres showing a clearly defined X-ray diagram of native cellulose with an angular dispersion of ~ 75°. (Copper $K\alpha$ radiation, D = 4 cm. (on original diagram).) The direction of the fibre axis is marked on the diagram with an arrow

a mean value of 72° with a small distribution peak at about 58°. The angular dispersion of the arcs in the X-ray diagram would also appear to indicate that the cellulose was oriented at an angle in the region of about 75°, thereby showing marked correlation with the optical observations. Where extensive development of the cellulose component has occurred (Fig. 1) these helical angles cannot be measured.

Hitherto, cellulose has only been reported in the plant kingdom, and in certain lower animals such as the Tunicata. Examination of the cellulose fibres present in the tunics of the sea squirt, *Ascidiella aspersa*, has shown that, in common with the highly anisotropic fibres found in mammalian tissue, the cellulose is associated with a protein fraction which is resistant to attack by the same enzymes and chemical reagents, and which has an amino-acid analysis between that of collagen and elastin.

On the basis of these observations it may be suggested that under certain conditions cellulose may be laid down on the surface of collagen fibres. This deposition occurs initially in helical form and afterwards in a similar fashion in successive layers (Fig. 2) resulting finally in a fibre, the protein core of which is completely covered with anisotropic cellulose. Electron microscope studies of such fibres have also shown the presence of finer fibrils arranged in layers. All the fibrils in any one layer lie parallel to one another, but they lie at an angle to those in adjacent layers.

From the point of view of collagen morphology, this phenomenon is of considerable interest since it would appear to indicate that collagen degradation products are capable of bringing about the orientation of highly anisotropic elements in a helical form. This may suggest the existence of an underlying helical structure in the collagen fibre itself. A helical structure has been used for explaining the molecular organization of collagen[3,4] and has also been observed at electron-microscope level in the early stages of thermal denaturation[5]. It is interesting to postulate that a helical structure persists at all levels of organization. Cruise[6] has reported the presence in a number of animal tissues of fibres having a brittle nature. Their properties appear similar in many respects to those of the fibres reported here.

As a first indication of the presence of cellulose in mammalian tissue these observations are of fundamental biological importance, especially in view of the fact that there is a marked similarity between the protein matrix to which the cellulose is attached, in both mammalian fibres and in those obtained from the Tunicata. The existence of cellulose as a component of mammalian tissue may, therefore, have considerable significance from an evolutionary point of view, but it may also have an equally profound impact on theories of tissue ageing.

A further account of these observations will be published elsewhere.

We wish to thank Prof. R. D. Preston for electron-microscope studies and Dr. W. Horton for assistance in the X-ray examination.

ADENOSINE TRIPHOSPHATASE AND CONTRACTION IN DEHYDRATED MUSCLE FIBRES

By SHEILA M. V. HUNT and N. A. MATHESON

Ministry of Agriculture, Fisheries and Food Research Establishment, The Experimental Factory, Aberdeen

WHEN raw meat or fish is dehydrated it tends to become rather tougher and less juicy after reconstitution and cooking than is the starting material. It was thought that this might be due to denaturation of actomyosin, the major protein of muscle in rigor. To investigate changes in the actomyosin, three of its properties were measured, namely, solubility in salt solutions of ionic strength 0·5 or greater, adenosine triphosphatase activity, and contractility in presence of adenosine triphosphate.

The meat and fish examined were dehydrated either by freeze drying in a vacuum desiccator or by the vacuum contact plate drying process[1,2]. In the former case strips of muscle (about 1 × 1 × 10 mm.) were put on a microscope slide with a few drops of water. The water was frozen solid in 5–10 min. The slides were transferred to a desiccator and dried *in vacuo* over sulphuric acid. The method used in the latter case has been described by Rolfe[3]. Here the foodstuff is freeze-dried for a few hours; its temperature is then slowly raised until it reaches 60° C., by which time the material is dry.

The effect of dehydration by both processes on the solubility of cod (*Gadus callarias*) muscle proteins has been investigated by Connell[4]. He found that extensive denaturation had occurred and that none of the structural proteins had remained in the undenatured state. It was also found in this work that the actomyosin of vacuum-contact plate-dried cod muscle was not soluble in 0·5 *M* potassium chloride or in 5 per cent sodium chloride if the extraction were done by allowing the ground fibres to stand overnight in the salt solution, or by blending them at half speed in an 'Atomix' with a close-fitting baffle to prevent foaming. On the other hand, when an 'Atomix' blender was used at full speed, the 'soluble' protein rose to 85–95 per cent of the total protein. This additional 'soluble' protein, however, was sedimented as the centrifugal force was increased in the range 800–16,000 *g*. It could also be removed completely by filtration through a fine paper (Whatman 42). No solubility measurements were done on meat since those on fish were so inconclusive.

The adenosine triphosphatase activity of both cod and beef was measured before and after dehydration

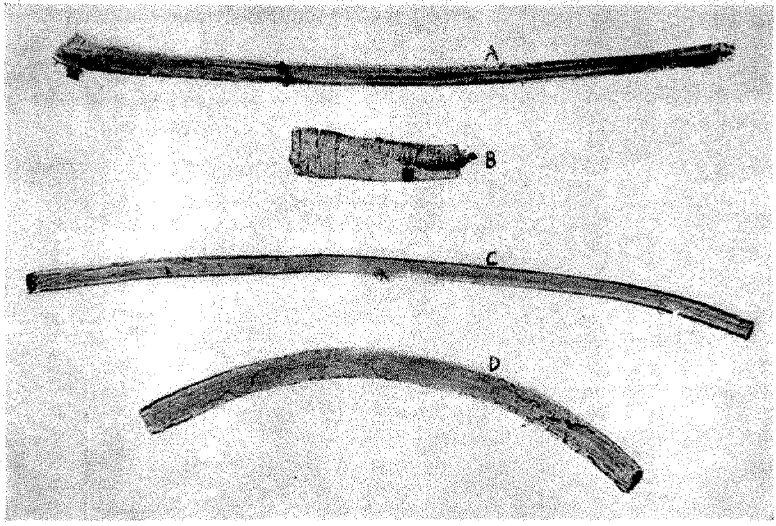

Fig. 1. Contractility of fresh and reconstituted, dehydrated, beef fibres on addition of adenosine triphosphate. *A*, fresh beef muscle fibre before addition of adenosine triphosphate; *B*, 5 min. after addition of adenosine triphosphate; *C*, dehydrated reconstituted beef muscle fibre before addition of adenosine triphosphate; *D*, 5 min. after addition of adenosine triphosphate. (× 50)

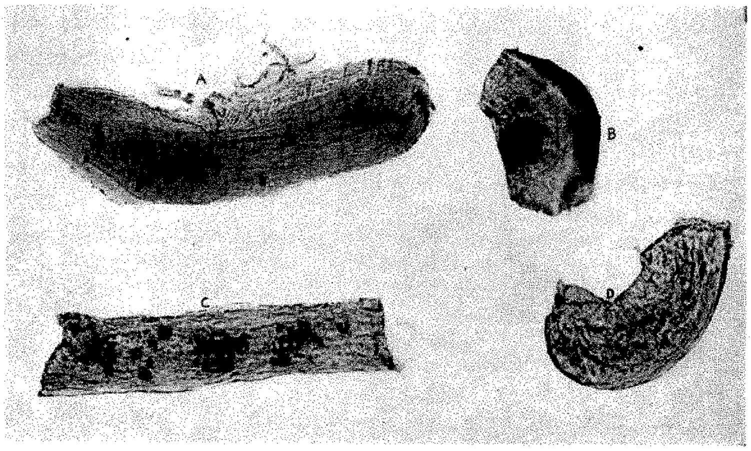

Fig. 2. Contractility of fresh and reconstituted, dehydrated cod muscle fibres on addition of adenosine triphosphate. *A*, fresh cod muscle fibre before addition of adenosine triphosphate; *B*, 15 min. after addition of adenosine triphosphate; *C*, dehydrated reconstituted cod muscle fibre before addition of adenosine triphosphate; *D*, 15 min. after addition of adenosine triphosphate. (× 30)

by the vacuum contact plate drying process. In these determinations the rate of liberation of inorganic phosphate from adenosine triphosphate by washed muscle preparations was measured with calcium as an activator. Calcium is probably not the physiological activator but it does promote actomyosin–adenosine triphosphatase without activating that of other tissue or apyrases. In every case examined, a proportion of the adenosine triphosphatase survived dehydration. In beef, the amount left varied from 40–80 per cent; in fish, about 50–75 per cent remained active. Loss of solubility and of enzyme activity are commonly used to show protein denaturation, but these results indicate that actomyosin could become insoluble in 0·5 *M* potassium chloride without losing its adenosine triphosphatase activity.

To obtain more evidence on the changes which occur in dehydration, beef and fish muscle were examined before and after dehydration for contractility in the presence of adenosine triphosphate. For this purpose, single fibres were removed by dissection with fine needles under the × 30 power of a stereoscopic microscope. These were then reconstituted in veronal buffer containing magnesium ions, and observed under the microscope while adenosine triphosphate was added. Beef fibres so treated always contracted whether they had been dehydrated by freeze-drying in a vacuum desiccator, or by the vacuum contact plate drying process. The dried, reconstituted fibres contracted to a smaller extent than the fresh and at a slightly slower rate. Like them they increased in cross-section as they shortened (Fig. 1). The contractility of dried beef fibres was not very easily destroyed by heat. Samples dried in a desiccator and heated in open dishes for 1 hr. at 22°, 37° and 55° were still contractile. At 70°, the power to contract was much reduced and at 100° it was completely absent.

The actomyosin in cod muscle fibres was much more labile. Fibres from cod fillets or steaks dried by the vacuum contact plate process never contracted in presence of adenosine triphosphate. Fibres from materials freeze-dried in a desiccator were sometimes contractile and sometimes not. The reason for this is not yet apparent though it is probably connected with the rate of freezing. Even when the fibres were contractile, they shortened less than similar fresh fibres and at a very much slower rate (Fig. 2).

From the above results it appears that cod actomyosin can be rendered insoluble by dehydration, but a large part of its adenosine triphosphatase activity, and sometimes even of its contractility, remains. Robinson had similar results with chicken actomyosin[5]. Solubility measurements are therefore not reliable criteria of denaturation though they do seem to measure some change which has occurred in actomyosin during drying.

Beef actomyosin is much more stable than that of cod. A large proportion of it is undamaged as measured by adenosine triphosphatase activity and contractility, after dehydration by freeze-drying or the vacuum contact plate process.

A detailed account of this work will be published elsewhere.

We wish to thank Mr. J. R. Bendall, of the Low Temperature Research Station, Cambridge, for his suggestion that contractility might be a useful method for studying the behaviour of actomyosin in dehydration.

Assay of Isotopic Nitrogen by Mass-Spectrometer

In a recent communication, Capindale and Tomlin[1] have pointed out some of the difficulties in measuring accurately the abundance of isotopic nitrogen (nitrogen-15), a measurement which is generally required when this isotope is used as a tracer in biological experiments.

One of the chief difficulties in estimating the abundance of isotopic nitrogen in small samples (20–300 μgm.) is the correction for contamination by air. Two methods are commonly used, each of them suffering from some drawbacks. One is based upon a measurement of the oxygen peak at mass number 32 and, by means of a predetermined nitrogen/oxygen ratio (28/32) for air ($\approx 5 \cdot 5$), correcting for contamination by atmospheric nitrogen. This method is accurate provided that all the oxygen in the sample comes from air, but is invalidated if any oxygen is formed by decomposition of hypobromite, when this is used for oxidizing the ammonia to gaseous nitrogen. The other method of correction is more specific in that it depends on measurement of the nitrogen/argon ratio (28/40); but it has the disadvantage that argon is present only in traces and experimental errors are magnified by the high nitrogen/argon ratio (≈ 73) in air.

Both methods have been tested in these laboratories during the course of work carried out by Yemm and Willis[2] and by Cocking[3]. More recently, it has been possible to apply corrections, based on measurements of the oxygen peak, with greater confidence by virtually eliminating the release of oxygen from hypobromite. As shown by Fleury[4], the decomposition, $2NaBrO \rightarrow 2NaBr + O_2$, is catalysed by traces of copper (Cu^{++}), but the decomposition is prevented by adding potassium iodide, which presumably forms a complex with the catalyst. Many tests have shown that no detectable release of oxygen occurs when 0·1 per cent potassium iodide is added to the hypobromite reagent. Moreover, by immersing the reaction vessel in liquid air after completion of the oxidation, it is possible to freeze out other by-products, such as nitrous oxide and carbon dioxide, which may interfere with measurements of nitrogen at mass numbers 28, 29, 30.

For routine analyses Rittenberg tubes[5], which can be fitted directly to the gas inlet system of a mass spectrometer, are convenient. By evacuating the tubes in two stages, first to about 10^{-2} mm. mercury by a mechanical pump (warming the solution to dispel dissolved gases) and then to about 5×10^{-5} mm. mercury by a backed mercury diffusion pump, nearly all the air can be removed prior to oxidation of ammonia by hypobromite. After the oxidation, the Rittenberg tube is attached to the mass spectrometer and immersed in liquid air to freeze out impurities. The gas is then expanded into a highly evacuated vessel of suitable volume (usually 50 ml.) for measurement of the peaks at mass numbers 28, 29, 30 and 32. In this way it is possible to obtain consistent measurements in samples containing as little as 30 μgm. nitrogen with very small or negligible corrections for contamination by air. Some typical examples of the estimates of nitrogen-15 abundance in amino-acids, separated chromatographically during the course of tracer experiments on yeast, are given in Table 1.

Table 1. Nitrogen-15 Abundance in Amino-Acids

Amino-acids	Nitrogen (μgm.)	Relative peak heights				Isotope abundance (atom per cent nitrogen-15)	
		Mass 28	Mass 29	Mass 30	Mass 32	28 : 29	28 : 29 : 30
Aspartic acid	92	280	28·25	0·700	0·600	4·86	4·85
Threonine	49	100	17·75	0·825	0·215	8·24	8·25
Serine	29	150	19·0	0·630	0·125	5·98	6·00
Glutamine	91	347·5	66·6	3·26	0·340	8·76	8·78
Glycine	30	189	23·6	0·775	0·125	5·93	5·96

In samples of gas containing about 5 atom per cent nitrogen-15 or above, it is possible to calculate the abundance either from the ratio of mass numbers 28 : 29 or from the measurements of the three peaks 28, 29, 30 (Rittenberg[6]). Close agreement between the two estimates is obtained, thus indicating the validity of the small correction for contamination by air, based on the measurement of the peak for oxygen at mass 32.

With the precautions outlined above, measurements have been made over a period of several months on replicate samples containing 30 μgm. nitrogen of a standard solution of an enriched ammonium salt; fifteen measurements had a mean of 31·67 atom per cent nitrogen-15 with a standard deviation of ±0·17.

We are indebted to Mr. B. Davis for measurements on the mass spectrometer, which were carried out in the Department of Chemistry in the University.

The work was supported by research studentships awarded by the Agricultural Research Council.

Mass-spectrometric Observations of Ions in Flames

As an extension of our studies of ionization in flames, previously based largely on conductivity measurements[1], an apparatus has been constructed for direct mass-spectrometric analysis of ions drawn from a flame. Whereas previously information about the nature and relative amounts of positive ions could only be obtained by inference from the electron concentration, it is now in principle possible to obtain directly the concentration of ions of any given mass number. It is the purpose of this communication to give preliminary qualitative results obtained with this apparatus, which prove to be of considerable interest.

In brief, the flame, burning at atmospheric pressure, is directed against a thin (0·002 in.) window in which is a small hole of about 0·002 in. diameter, which samples about 1/4 c.c./sec. from the flame into a chamber, evacuated to $\sim 10^{-3}$ mm. by means of a fast pumping system. Using a series of ion lenses, it is found possible to direct a beam of ions into the slit of a conventional sector-type mass spectrometer, and thus to obtain a mass analysis. Ion concentrations down to 10^7 ions/c.c. in the flame are readily detectable.

So far, premixed hydrogen–air and acetylene–air flames have been studied (temperatures ~2,200° K.) and sprays of salts of the alkali and alkaline earth metals have been added, and the resulting ions investigated.

A feature common to all the simple ions found is an apparent facility of attachment of one or two, or even, to a small extent, three water molecules to the parent ion. It is not yet established whether these hydrated ions occur in the flames, or are formed at some stage of the sampling process, but the latter seems more probable.

In hydrogen flames with no additive, the main ion in the gases above the reaction zone appears to be H_3O+, with a smaller peak corresponding to the attachment to this of a water molecule. There is also a fairly large peak at mass 18, which is thought to be due to H_2O+. There are also traces of Na+ and K+, which seem to be inevitable, at least when using compressed air to run the flame.

On spraying salts of alkali metals into the flame, the expected peaks of the simple ions Li+, Na+, K+, Cs+ appear strongly, and also those of the hydrated ions, increasingly weaker as one, two and possibly three molecules of water are attached. On spraying a solution of strontium chloride into the flame, the ion peaks of Sr+ appear, but somewhat stronger peaks appear seventeen mass numbers higher, which correlate with the ion SrOH+, previously postulated by Sugden and Wheeler[2] on the basis of electron concentration measurements. A small peak at mass number 106 confirms the presence of some of the first hydrate of Sr+, and likewise the second may be detected. Ion peaks corresponding to $SrOH+nH_2O$ may be detected up to $n = 3$. Similar results are found with calcium and barium, except that Ba+, if present, is below the limit of detection, and the hydroxide ion is predominant.

The flames of acetylene provide a more complicated system, and on sampling the primary reaction zone of an acetylene–air flame (near-stoichiometric mixture), ion peaks of varying sizes were found at almost every mass number up to 100. No analysis of this has yet been attempted. In the gases above the reaction zone, the ions are fewer both in number and in type. The peaks observed in hydrogen flames appear also in these, and the only additional prominent peak appears at mass number 30 (with its first hydrate at 48). The most likely formula for this is CH_2O+ or NO+. Further, it may be said, in the former case, that this is probably ionized formaldehyde rather than hydrated carbon, since no indication of the presence of C+ was found. The appearance of this ion in the upper parts of the flame, and the disappearance of other ions just above the reaction zone, merit much further study.

It is our aim to extend this work as both a qualitative and quantitative study with various types of flame and metallic elements, and to publish details of the apparatus and further results in due course.

We wish to express our gratitude to the Research Laboratory of the General Electric Company of Schenectady, New York, for a grant in support of this work.

Burning Voltage of Arcs in High Vacuum

In the course of an investigation of high-current arcs between solid electrodes in vacuum, an empirical relationship between arcing voltage and physical properties of the cathode material has been found. Certain exceptions are significant because, except for carbon, they are all ferromagnetic metals or alloys containing a ferromagnetic metal.

The burning voltage of an arc between two electrodes in vacuum is almost constant, increasing only very slightly with increase of current and depending in the main only on the nature of the cathode material. This applies provided that the anode subtends a large solid angle at the cathode, so that electrons and metal vapour ejected from the cathode spot or spots may follow line of sight paths to the anode. It is from the metal vapour ejected from the cathode spot or spots that the positive ions (which serve to neutralize the electronic space charge) are derived. The loss of positive ions from the discharge is small, so that the voltage gradient at any point in the discharge clear of the immediate neighbourhood of the cathode spot is negligible.

Although the arcing voltage of any particular metal is not steady, but contains high-frequency components, its average value is remarkably constant. The anode material does not normally affect the burning voltage, because the anode rapidly becomes coated with a thin film of material ejected from the cathode spot.

In Fig. 1, burning voltage is shown plotted against the product of boiling point and thermal conductivity of the cathode material. Normal temperature thermal conductivities have been used, because few data exist on thermal conductivities at elevated temperatures.

It is apparent that, with the exception of carbon and non-magnetic stainless steel, the arcing voltages of the non-ferromagnetic metals lie on or very near to a smooth curve, while the voltages of arcs on the ferromagnetic materials lie above the curve by an

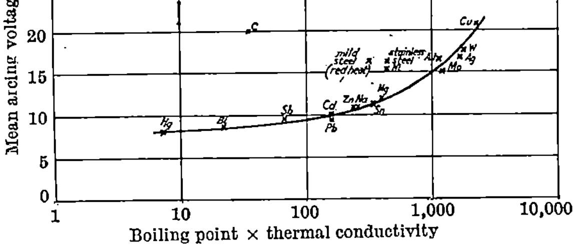

Fig. 1. Empirical relationship between arcing voltage in vacuum and physical properties for some common metals

amount that increases with the Curie point of the metal.

For steel the arcing voltage of 33 V. drops to 16·2 V. when the bulk of the metal is raised to a temperature at which it is a bright red, above the Curie point.

These results, which will be described fully elsewhere, give very considerable support to a new theory of electron emission from non-thermionic cathode spots, outlined in the following communication.

The Arc Cathode

IT is generally agreed that none of the theories that has been suggested gives a complete and convincing account of the mechanism of the non-thermionic arc cathode. Combinations of, say, thermal and field emission do not fare much better, particularly for cases like the mercury arc cathode[1]. What follows is a new approach which goes some way, if not all the way, towards a satisfactory theory.

In the pinch effect in a plasma the inward radial force is balanced by an increase in gas pressure which is, of course, unbalanced axially. The plasma maintains its state of electrical neutrality under the pinch forces. If, however, we consider what occurs in the metal, the fact that the positive charge centres—the crystal lattice points—are not free to move means that the pinch-effect forces are not balanced by an electron gas pressure but by space-charge forces: that is, the pinch effect sets up a negative space charge in the region of high current density near the cathode spot. The density of this space charge is easily shown to be:

$$\rho = \mu\varepsilon J\bar{v} \qquad (1)$$

where μ and ε have their usual meanings, J is the current density, and $\bar{v}$ is the mean velocity of the electrons carrying the current just inside the metal surface. But the electrons that can escape across the potential boundary must have energies greater than $W + \varphi$, where W is the Fermi energy and φ the work function, and so the appropriate value of $\bar{v}$ in equation (1) is of the order of

$$[(2/m)(W + \varphi)]^{1/2} \qquad (2)$$

Near the surface, therefore, the Fermi equilibrium is disturbed; there is a deficit of high p_z electrons, and to restore equilibrium a corresponding number of $-p_z$ electrons would require to be injected. These high $-p_z$ electrons would gradually degenerate to mean p_z as we move in from the surface and simultaneously the current would be transferred to the normal drift velocity appropriate to the centre of the metal. It is this 'slowing-down' length that determines the fall-off in space charge density as we move inwards from the surface.

The effect of the negative space charge is to lower the potential barrier and therefore the effective work function φ by an amount $\Delta\varphi$ which is of the order of $\mu\varepsilon J\bar{v}\Lambda^2 e$, where Λ is the slowing-down length. Characteristic values show this to be about 2–3 eV. in the case of, say, copper. Note that the value of φ in (2) must now be replaced by $\varphi - \Delta\varphi$. At high temperatures, where the simplified form of the Fermi distribution can be used, we then get an expression for the current density given by (Richardson formula):

$$J = AT^2\exp(-\varphi/kT)\exp(\Delta\varphi/kT) \qquad (3)$$

where $\Delta\varphi$ is the solution of:

$$\Delta\varphi \sim \mu\varepsilon J\Lambda^2 e[(2/m)(W + \varphi - \Delta\varphi)]^{1/2} \qquad (4)$$

that is to say, (3) is an implicit equation for J.

The space charge produced by the pinch effect is thus responsible for lowering φ sufficiently to account for the electron emission.

This changes much of the usual picture. The current density in the metal produced in this way, together with the increased resistivity $(\propto p^2)$ is responsible for the heating and evaporation of the metal at the cathode spot, which is therefore a purely secondary effect. The molten metal will itself have higher resistivity, and the depth of liquid below the surface is therefore involved. The result is that there is a considerable ohmic voltage drop *within* the metal. This has been pointed out by Reece (previous communication), who has shown, in the case of vacuum arcs, that the arc voltage is a function of the boiling point of the metal multiplied by the thermal conductivity of the metal and that a large part of the cathode fall is accounted for in this way. An unusual feature of the theory is the dependence on μ, which will have the effect of increasing the current density and therefore the cathode fall in the ferromagnetic metals. This is strikingly corroborated in Reece's experiments. Again, since there is always a parallel path of lower resistance through cold metal, the position of the arc is inherently unstable and hence must be in continual random movement.

Another consequence of this theory is that the time of disappearance of the cathode mechanism is just that of the dispersal of the electron space charge in the metal. It is in fact of exactly the same order as that observed for mercury arcs, namely, 10^{-9} sec.

There are several other consequences of the theory which, together with a more complete theoretical treatment and numerical verification, will shortly be published elsewhere.

Preliminary Investigations of the Silicon Boride, SiB_6

ALTHOUGH there has been a good deal of experimental work on the borides of silicon dating back to Moissan[1], current reports (ref. 2 and Parthe, E., M.I.T., private communication) have been somewhat confusing as to the exact phases present in the boron–silicon system. We now wish to report that we have prepared single crystals of silicon boride (SiB_6) by fusion of the elements. The wet chemical analysis after removal of excess silicon agrees with stoichiometric values for the compound SiB_6 as are shown by the following determinations:

B—69·05, 70·16, 69·3
Si—29·43, 29·48, 30·4

The density as determined by pycnometer methods is 2·45 gm./c.c.

Preliminary investigations of the compound by Laue and rotation photographs have indicated an orthorhombic unit cell with approximate lattice parameters of $a = 14{\cdot}60$ A., $b = 18{\cdot}40$ A., $c = 10{\cdot}02$ A. Based on the pycnometer density of 2·45 gm./c.c. the unit cell contains 42·7 molecules. These values confirm facial indices and axial ratios found from optical goniometer measurements. The structure appears to be quite complex, and further work using Weissenberg camera measurements will be necessary before an exact structure can be reported.

Electrical, hardness, and melting-point determinations indicate that the compound has interesting physical properties which are being investigated.

Permeability and the Size Distribution of Pores

A RECENT communication by T. J. Marshall[1] directs attention to a formula for calculating the permeability of a porous medium from its pore-size distribution. This appears to be derived from an implicit model for a porous structure which is very similar to a model which we have found useful at the Gulf Laboratories. However, the formulæ which we derive are somewhat different from Dr. Marshall's.

The physical model, which we believe can be used advantageously to represent actual porous rocks, may be conceived in the following way. Consider a cylindrical bundle of straight capillary tubes the radii of which have a suitable range. Cut this bundle into thin slices, of equal thickness, perpendicular to its axis. Re-arrange randomly the pieces of tube in each slice and then reassemble the slices to form a cylindrical core. This structure of randomly interconnected capillary tubes of various radii forms the model which we have used for studying linear flow.

In any homogeneous porous body a plane section exposes a pore distribution the total area of which is a fraction φ of the area of the section, where φ is also equal to the volumetric measure of porosity. Hence, in any slice of the model the total area available for flow is φ times the area of the slice. Because of the random interconnexion between adjacent slices, however, the total area available for flow at the junctions is reduced to φ^2 times the area of a slice.

Based essentially on this idea, we have worked out formulæ relating capillary pressure, absolute and relative permeabilities, electrical resistivity index and formation factor. We have also set up a theory for the displacement of a fluid from a porous medium by a miscible fluid. Details will be published elsewhere.

It is noteworthy that the expressions we get for permeabilities are essentially the same as those derived empirically by Burdine[2]. A comparison with some of the available experimental work can be found in his paper. In view of the simplicity of the model, the general agreement between predicted and observed results is surprisingly good. It cannot be said, however, that an unequivocal conclusion has been reached.

[2] Burdine, N. T., *Trans. Amer. Inst. Mech. Eng.*, **198**, 71 (1953).

FROM the preliminary information and the reference given by Dr. Wyllie and Dr. Gardner, it appears that the difference in their permeability equations may arise from their use of a term for tortuosity. I have avoided this mainly by allowing for the effect of imperfect fit and dead ends and the effect of the smaller pore in a sequence on the average size of the necks connecting the pores. Further details are given in a paper[1] which is to appear shortly.

Effect of Plastic Deformation on the Electrical Resistivity of Chromium

THE presence of a transition in the electrical resistivity and temperature coefficient of resistance of chromium in the region of 40° C. has been reported by several investigators[1]. In studying the influence of plastic deformation (at 150° C.) on high-purity chromium an anomaly has been found, in that below the transition temperature the deformed material had a lower resistivity than the annealed. Curves of resistivity versus temperature are shown in Fig. 1, together with the respective temperature coefficients of resistance. No hysteresis was observed in these measurements. A positive deviation in the temperature coefficient of resistance of the deformed material is observed both below and above the transition temperature. A minimum in the curve of resistivity versus temperature for the annealed material (Fig. 1) occurs at 41° C. and is in close agreement with other workers. Particulars of the specimen material are recorded in Table 1. As shown in Fig. 2, a change in the sign occurs, from negative to positive, in the value of $\Delta\rho$ (the difference in resistivity between the deformed and the annealed material) on increasing temperature through the transition region, namely, $-40°$ C. to $+40°$ C.

Table 1. RELEVANT HISTORY OF THE SPECIMEN

Analysis of chromium* (per cent)		Analysis of chromium* (per cent)	
Mg	< 0·0002	Ag	0·0001
Pb	0·0002	Ti	trace
Si	< 0·0005	C	< 0·0015
Al	0·0005	O_2	< 0·013
Fe	< 0·0005	N	< 0·0005
Cu	0·0002	H_2	< 3·0 ml./100 gm.

* All metallic elements determined spectrographically. (*a*) Specimen dimensions: 0·027 in. (0·073 cm.) diameter, 8·3 in. (20·7 cm.) length. (*b*) Specimen history: arc melted electrolytic chromium ingot (1·5 in. diameter) → extruded bar (0·5 in. diameter) → swaged rod (0·2 in.) diameter) → wire drawn to 0·027 in. diameter at 300° C. final 3 per cent reduction at 150° C. Total reduction in area 98 per cent. (*c*) Annealing treatment: 700° C. for 15 min. *in vacuo* (2×10^{-4} mm. of mercury); specimen completely recrystallized after this treatment.

Previous investigators[2] have reported changes in other physical properties of chromium in this temperature region although no satisfactory explanation for this transition has so far been given. It has been suggested[3,4] that the transition may be associated with a magnetic change at about 40° C. in residual chromic oxide (Cr_2O_3).

From the generally similar shape of the curves of temperature versus resistance for specimens annealed or plastically deformed, it seems reasonable to assume that the factors influencing the transition are similar in both states. Above the transition temperature the normal increased resistance in deformed material is observed; this is due to the scattering of conduction electrons by the lattice defects introduced during the deformation process. However, below the transition temperature, after deformation a modification must occur to that part of the resistance dependent on temperature, which in this particular case more than compensates for the scattering produced by lattice defects and leads to an overall decrease in the resistance relative to the annealed material. This modification is manifested as a 5 per cent decrease in resistivity on superimposing the positive value of $\Delta\rho$ at 70° C., on the $\Delta\rho$ value at $-60°$ C. (Fig. 2) and suggests a deviation from the normal electronic structure for chromium below the transition temperature, the normal structure being taken as that state which is essentially consistent with Matthiessen's rule.

Both Thomas[5] and Linde[6] have reported a decrease in resistivity in gold/chromium alloys with cold work and Linde[7] has postulated a change in the dynamic equilibrium between the electrons in the 3*d*- and 4*s*-shells in certain chromium atoms after cold work. The net result of this exchange is a reduction in the capture of conduction electrons by the *d*-shells by virtue of the more stable electron configuration attained by certain atoms, probably those displaced most from their lattice positions. This explanation has been supported by magnetic measurements on cold worked alloys of gold and chromium[8] which have shown a change in magnetic susceptibility corresponding to an increase in the number of electrons bound to the 3*d*-shell.

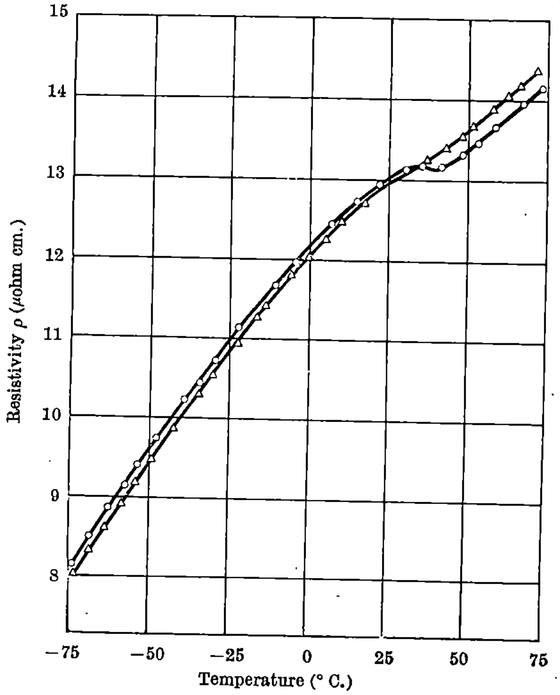

Fig. 1. Resistivity of annealed (○) and deformed (△) chromium as a function of temperature

Temperature range (° C.)	Temperature coefficient of resistance × 10^3	
	Annealed	Deformed
− 70 to − 45	7·16	7·40
45 to 70	2·50	2·58

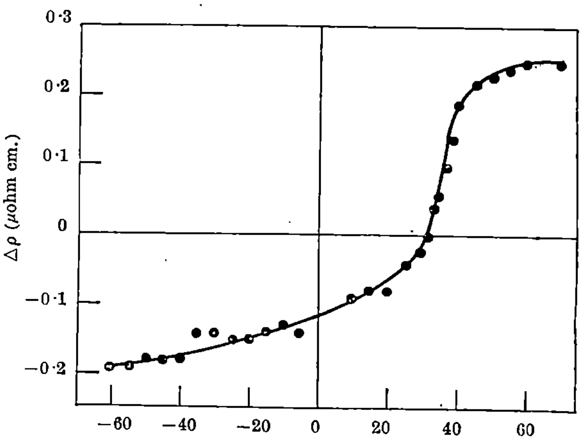

Fig. 2. Variation of $\Delta\rho$ with temperature

Electrolytic chromium is characterized by an increase in magnetic susceptibility with increasing temperature[3,9]. No irregularities have been observed in the susceptibility near the transition region. An antiferromagnetic superlattice has been detected by neutron diffraction experiments[10] at very low temperature with a Néel temperature of 200° C. Unfortunately no magnetic measurements are available for chromium in the worked condition to check the Linde hypothesis with respect to very pure chromium. It would seem, however, that the fundamental reason underlying the decrease in resistance is the abnormal electronic state present below the transition temperature and that the effect of deformation will not be fully understood until this state is defined and the reason for the transition determined.

A detailed report on the resistance measurements of chromium will be published elsewhere. Acknowledgment is made to Mr. J. I. Nish for his encouragement throughout this work and to the Chief Scientist, Department of Supply, Australia, for permission to publish it.

Oxygen-cutting of Vanadium

The mechanism controlling the oxygen-cutting of iron and steel has been investigated by this Association, primarily along the lines of previous work by Wells[1], whereby attention was focused on the iron/oxygen combustion process. Recently this work has been extended to the study of the general conditions governing the progress of flame cuts through elementary materials, propagated by combustion with a pure gaseous element. The situation has been analysed in some detail for oxygen and chlorine. With the halogen gases, melting points of the elements most likely to be cut appear to be below the ignition temperature in the gas; no cuts were obtained in the cases of zinc and magnesium, which were otherwise thought to be likely to respond. Other halogen gases have not been tested experimentally, though it is known that fluorine may be used for flame-cutting copper[2].

In the field of oxygen-cutting, probable natural flame-cutting elements are iron, titanium, vanadium and antimony. Experimentally, the latter element does not ignite below its melting point, but the first three are readily cut. Iron and steel cutting by oxyacetylene, hydrogen, propane, coal-gas or oxy-arc processes, has, of course, been in use for many years. Flame-cutting of titanium by the oxyacetylene process has formed the subject of a detailed report[3], as it was not realized that the process was known in the United States[4], though investigations by this Association were conducted independently.

Vanadium was selected as a trial element, since no previous tests were known, and, owing to the high cost of the material and its scarcity in massive form, it would be unlikely to be attempted outside a research laboratory. Because of the extremely poisonous nature of the vanadium oxides, it is necessary to conduct the cutting operation in a closed chamber, progress being viewed through a glass window. Two successful cuts have been made in a vanadium plate 11 cm. × 5 cm. × 0·6 cm. obtained through the courtesy of the United Kingdom Atomic Energy Authority. The first cut was made manually and the second with a motor-driven oxyacetylene torch at 32 in./min. traverse speed. The surfaces near the pre-heat initiation point were contaminated with condensed vanadium metal and oxide, but away from the pre-heat area contamination was limited to a temper-coloured zone about $\frac{3}{8}$ in. on either side of the cut edge. There was no appreciable hardening on the surface of the plate to within $\frac{1}{32}$ in. of the cut. As in titanium, the major deleterious effect would be expected to be oxygen pick-up by the edge. Owing to the high reactivity of vanadium, its flame-cutting properties would be expected to be more akin to titanium than to mild steel.

Apart from confirming previous conceptions of the process, the successful test on vanadium makes it likely that alloys of the iron–titanium–vanadium system would be 'cuttable' by oxygen methods.

A more detailed account of this work will appear elsewhere.

Structure of Cupric Salts with Mono-, Di- and Tri-chloroacetic Acids

In former communications[1], we reported that the cupric salts, anhydrous or hydrated, with *n*- and *iso*-monocarboxylic acids might consist of the dimeric molecules having a sort of copper-to-copper linkage. In continuation of these researches, we have recently examined the structure of cupric salts with mono-, di- and tri-chloroacetic acids, using the criteria previously derived: (1) the cupric alkanoates involving the dimeric molecules show, in addition to a band at about 43 × 10^{13} c./s., an absorption band of a special kind at about 80 × 10^{13} c./s., which was regarded as due possibly to the presence of the copper-to-copper linkage; (2) the polarization of the latter band is the reverse of the polarization of the former.

The present measurements indicate that cupric monochloroacetate and dichloroacetate in dioxane show absorption spectra which are closely similar to those of the cupric alkanoates in solution, showing an absorption band of the special kind at about 80 × 10^{13} c./s. The dichroism in the visible and ultra-violet of the two compounds has been determined quantitatively by Tsuchida–Kobayashi's microscopic method[2]. The crystals of cupric monochloroacetate tetrahydrate and anhydrate, and of anhydrous cupric dichloroacetate all show absorption bands at about 41 and 80 × 10^{13} c./s. besides strong absorption in the shorter wave-length regions. The polarization of the band at about 80 × 10^{13} c./s. is found to be the reverse of the polarization of the band at about 41 × 10^{13} c./s. These relationships bear a close resemblance to those with the cupric alkanoates, suggesting the existence of dimeric molecules similar to those of the alkanoates. Thus it may be concluded that cupric monochloroacetate and dichloroacetate have the dimeric molecules in dioxane and in the crystalline state. The dimeric molecules may be represented by $Cu(R.COO)_4$ or $Cu(R.COO)_4.(OH_2)_2$.

In contrast to the above mentioned compounds, cupric trichloroacetate in dioxane shows only one absorption band at about 40 × 10^{13} c./s. in the corresponding wave-length range. Furthermore, cupric trichloroacetate tetrahydrate in the crystalline state displays polarized absorption spectra having only the absorption band at about 40 × 10^{13} c./s. Thus the spectra of the compound are found to be quite different from those of the other two compounds. It is concluded, therefore, that the trichloroacetate does not involve the dimeric molecules in the crystalline state or in dioxane.

Cupric dichloroacetate is known to exist in a tetrahydrate as well. The dichroism of this form is not quite identical with that of the anhydrous form, which is shown to consist of the dimeric molecules. The structure of the tetrahydrate in the crystalline state is under investigation.

Time Variation of Chemical Affinity

In two previous communications[1,2] we have shown that an accelerated chemical reaction is always characterized by the variation of the chemical affinity of the system with time. For a reaction with constant velocity this time derivative would, of course, be zero. In this communication we shall consider further the properties of the function $\dot{A} \equiv (\mathrm{d}A/\mathrm{d}t)$. A is the instantaneous chemical affinity defined by

$$A = -\sum_i \nu_i \mu_i \tag{1}$$

In this equation, ν_i is the stoichiometric coefficient, and μ_i is the instantaneous chemical potential of the ith component. Since this potential is a function of the activity of the particular substance, it will vary with concentration, and hence with time. Bearing this in mind, we can now differentiate equation (1) with respect to time :

$$\dot{A} = -\sum_i \nu_i \mu_i \tag{2}$$

Throughout this discussion the pressure and temperature will be assumed constant.

Utilizing the definition of μ_i in terms of the activity coefficient[3]

$$\mu_i = \mu_i^0 + RT \ln a_i$$

where a_i is the activity of the component i and μ_i^0 is the chemical potential of this substance in the arbitrary standard state, we obtain

$$\mu_i = RT\, \mathrm{d}/\mathrm{d}t(\ln a_i).$$

By substitution in equation (2) we have

$$\dot{A} = -RT \sum_i \nu_i\, \mathrm{d}/\mathrm{d}t(\ln a_i) \tag{3}$$

This equation can alternatively be established from the relation[3] between the affinity and the equilibrium constant K :

$$A = RT \ln K - RT \ln \prod_i a_i^{\nu_i}$$

Differentiating this relation with respect to time, we get

$$\begin{aligned} \dot{A} &= -RT\, \mathrm{d}/\mathrm{d}t\, (\ln \prod_i a_i^{\nu_i}) \\ &= -RT\, \mathrm{d}/\mathrm{d}t(\sum_i \nu_i \ln a_i) \\ &= -RT \sum_i \nu_i\, \mathrm{d}/\mathrm{d}t(\ln a_i) \end{aligned} \tag{3a}$$

If the behaviour of the substances participating in the reaction tends to ideality, we may replace activities by concentrations (that is, the activity coefficient can be regarded as unity for our purposes). Thus,

$$\dot{A} = -RT \sum_i \nu_i\, \mathrm{d}/\mathrm{d}t(\ln c_i)$$

where c_i is the concentration of the ith component at any instant. As an approximation, therefore, we arrive at $\dot{A}$ from the experimental observation of the change of ($\ln c_i$) with time. We should note, of course, that the rate of change of concentration with time is related to the reaction velocity, but in the case of the accelerated reaction under consideration the velocity has different values with successive instants of time.

For the sake of completeness we can show how the acceleration of a chemical reaction may be related to the time variation of the chemical affinity.

We can define the acceleration and velocity of a chemical reaction by

$$v = \mathrm{d}\xi/\mathrm{d}t \text{ and } \dot{v} = \mathrm{d}^2\xi/\mathrm{d}t^2$$

where $\mathrm{d}\xi = \mathrm{d}n_i/\nu_i$ (n_i is the mole number of the ith component). Previously[1] we formulated the relation

$$\dot{v} = (\dot{A}/A)v$$

which, in terms of equation (3), becomes

$$\begin{aligned} \dot{v} &= \frac{-RT \sum_i \nu_i\, \mathrm{d}/\mathrm{d}t(\ln a_i)}{RT \ln K - RT \ln (\prod_i a_i^{\nu_i})} v \\ &= \frac{-\sum_i \nu_i\, \mathrm{d}/\mathrm{d}t(\ln a_i)}{\ln K - \ln(\prod_i a_i^{\nu_i})} v \end{aligned}$$

or approximately,

$$\dot{v} = \frac{-\sum_i \nu_i\, \mathrm{d}/\mathrm{d}t(\ln c_i)}{\ln K - \ln(\prod_i c_i^{\nu_i})} v \tag{4}$$

However, from the experimental point of view it is much simpler to obtain the acceleration directly from the definition

$$\dot{v} = \frac{\mathrm{d}^2\xi}{\mathrm{d}t^2} = \frac{1}{\nu_i} \frac{\mathrm{d}^2 n_i}{\mathrm{d}t^2} = \frac{1}{\nu_i} \frac{\mathrm{d}^2(Vc_i)}{\mathrm{d}t^2} \tag{5}$$

where V is the volume. Equation (5) implies that data for only one reactant are required to compute the acceleration. Equation (4) can thus claim no heuristic value, but is relevant to our discussion as a merely theoretical deduction.

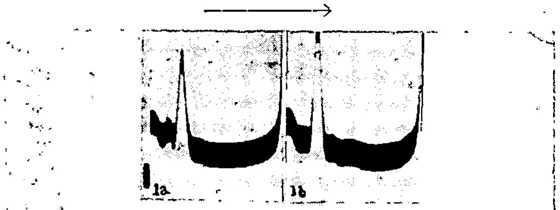
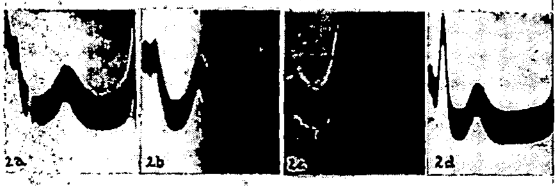
Complex Formation between Groundnut Skin Pigments and Conarachin II

When defatted groundnut meal containing a portion of the red skins of the nut was extracted with 10 per cent (w/v) sodium chloride solution and the extract dialysed against phosphate-sodium chloride buffer, ionic strength I 0·5, *p*H 8, the sedimentation-velocity diagram (Fig. 1*a*) revealed the presence of three components : arachin, the major component (sedimentation constant, $s^\circ_{20} = 13{\cdot}3$ S., conarachin II ($s^\circ_{20} = 8{\cdot}4$ S.) and conarachin I ($s^\circ_{20} \approx 2$ S.)[1]. When the extraction was carried out at *p*H 8–9 with sodium hydroxide, the solution was considerably more red in colour, the conarachin II component was less apparent, and the presence of a fourth, very fast sedimenting component ($s^\circ_{20} = 32$ S.) was observed (Fig. 1*b*). This fast component was absent, however, in extracts of blanched nuts or white skinned nuts. It would therefore appear to be connected with the presence of the red skin pigments in the meal.

The addition of calcium chloride (4 gm./l.) was found to precipitate most of the protein from a *p*H 8–9 extraction liquor leaving the colour in the supernatant liquor. When the latter was saturated with ammonium sulphate, the remaining protein precipitated along with the red pigment leaving an





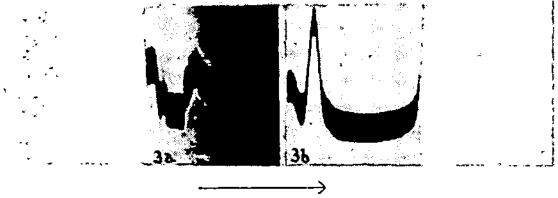


Fig. 1. Sedimentation diagram of: *a*, 10 per cent sodium chloride extract; *b*, (*p*H 8)-extract of groundnut meal containing some of the red skins. Both extracts dialysed to *I* 0·5, *p*H 8. Protein concentration, 1 gm./100 ml.

Fig. 2. Sedimentation diagrams in (*I* 0·5, *p*H 8)-buffer of: *a*, protein in supernatant of a (*p*H 8)-extract of groundnut meal after addition of calcium chloride: (4 gm./l.); *b*, 65/85 ammonium sulphate fraction of the supernatant; *c*, sediment after solution-*b* was spun in ultracentrifuge at 150,000*g* for 3 hr.; *d*, protein left in supernatant after (*p*H 8)-extract of meal was saturated to 65 per cent with ammonium sulphate. Protein concentration, 1 gm./100 ml.

Fig. 3. Sedimentation diagrams of: *a*, conarachin II (*I* 0·5, *p*H 8) + dark coloured (*p*H 9)-extract of red skins of the groundnut; *b*, conarachin II at *I* 0·5, *p*H 8

almost colourless supernatant. The precipitate in (*I* 0·5, *p*H 8)-buffer gave a dark red solution and the sedimentation diagram of Fig. 2*a*. If the supernatant, after the calcium chloride precipitation, was first 65 per cent saturated with ammonium sulphate, the protein which precipitated was not coloured. Further saturation from 65 to 100 per cent with ammonium sulphate produced a dark precipitate, giving in (*I* 0·5, *p*H 8)-buffer the sedimentation diagram of Fig. 2*b*. This diagram shows the presence of a higher proportion of the s_{32} component. The solution giving Fig. 2*b* was then centrifuged at 40,000 r.p.m. (150,000*g*) in the preparative head of the 'Spinco' Model *E* ultracentrifuge for 3 hr., and the sediment, when dissolved in (*I* 0·5, *p*H 8)-buffer, gave an extremely dark coloured solution and the sedimentation diagram of Fig. 2*c*. It will be observed that the proportion of s_{32}-component in this diagram is greater than that in Fig. 2*b*. This fast component was also observed in the supernatant after an extract of *p*H 8–9 of groundnut meal was 65 per cent saturated with ammonium sulphate (Fig. 2*d*). Its presence was only observed in highly coloured solutions.

When the solution giving Fig. 2*c* was dialysed against buffers at *I* 0·5 in the *p*H range 5–11 no change in the sedimentation diagram was observed. The addition of 5 *M* urea caused no change in the sedimentation diagram. When, however, the solution giving Fig. 2*c* was extracted with methyl ethyl ketone, a known solvent for vegetable tannins[2], the colour was removed from the solution, and the s_{32}-component was replaced by a component of sedimentation constant close to that of conarachin II. It thus appeared that the s_{32}-component was a complex between conarachin II and the groundnut skin pigments.

In order to confirm this, it was decided to attempt a synthesis of the complex from the protein and the pigments. The red skins of groundnuts were extracted at *p*H 9 with sodium hydroxide. Some of the very dark extract was then added to each of the three groundnut–protein fractions, arachin, conarachin I and conarachin II dissolved in (*I* 0·5, *p*H 8)-buffer. With arachin and conarachin I orange precipitates were formed. With conarachin II, however, no precipitation occurred, and the solution in the ultracentrifuge gave the sedimentation–velocity diagram of Fig. 3*a*, which shows the presence of a fast sedimenting component ($s^{\circ}_{20} \approx 32$ S.) but more polydisperse than the s_{32} component of Fig. 2. The diagram for conarachin II itself is shown in Fig. 3*b*.

The presence of four pigments in groundnut testa (tannin, phlobaphene, leuco-anthocyanin and flavone) has been reported[3]. Since the red tannin is the water-soluble pigment it seems probable that the complex is formed between conarachin II and the tannin. In view of the considerable increase in the sedimentation constant of conarachin II (8·4 → 32 S.) it would appear that some cross-linking of the protein by the tannin occurs to form the complex.

Isolation of 2-Nitro-phenol from the Mixture of Mono-nitro-phenols

2-Nitro-phenol is usually prepared from the mixture of mono-nitro-phenols obtained by nitration of phenol. According to the classical methods[1] the isomers can be separated by steam distillation, as the steam volatility of the 2-nitro product is higher than that of the 3-nitro- or 4-nitro-phenol. The 2-nitro-phenol obtained by these methods, however, is usually contaminated by more or less of the 3-nitro- and 4-nitro-isomers. A number of interesting publications have appeared on the preparation of the pure products[2].

A convenient method of isolating practically pure 2-nitro-phenol has been devised, which may be used for avoiding the adoption of the steam distillation in certain cases, and is also suitable for further purification of the steam distillate. Apart from its use in the laboratory, the procedure has potential industrial application in working up mixtures of nitro-phenols obtained either by nitration of phenol or by hydrolysis of nitro-chloro-benzenes.

The method is based on the different solubilities of the sodium salts of mono-nitro-phenols in dry ethanol. As the sodium salt of 2-nitro-phenol[3] has the lowest solubility among them, it can be separated from an adequately concentrated alcoholic solution of mono-nitro-phenols by adding sodium ethylate. Having a mixture of sodium salts of the nitro-phenols, the sodium 3-nitro-phenoxide and 4-nitro-phenoxide can be dissolved with a suitable quantity of dry ethanol, while the sodium salt of the 2-nitro-phenol remains undissolved. In choosing the appropriate quantity of the solvent it must be taken into consideration that 3·9–4·0 gm. of sodium 4-nitrophenoxide and 0·4–0·5 gm. of sodium 2-nitrophenoxide, respectively, can be dissolved in 100 ml. of dry ethanol at 20° C.

Isolation of 2-nitro-phenol from the solution of mono-nitro-phenols. 2·5 gm. of 4-nitro-phenol and 7·5 gm. of 2-nitro-phenol (melting point, 43·5–44·5° C.) are dissolved in 45 ml. of dry ethanol, then 27 ml. of a solution of sodium ethylate (1·35 gm. of sodium metal dissolved in 27 ml. of dry ethanol) is added, and allowed to stand for an hour at room temperature. The sodium salt of 4-nitro-phenol remains dissolved, while the red-coloured sodium salt of 2-nitro-phenol separates. After filtration it is washed successively three times with 20 ml. and once with 7 ml. of dry ethanol cooled in ice, finally with two 15-ml. portions of benzene, and dried at 105° C. The sodium-2-nitro-phenoxide thus obtained (7·6 gm., 87 per cent yield) is converted into the phenol by treatment with 28 ml. of 5 *N* sulphuric acid on a steam-bath, and then allowed to stand overnight in a refrigerator. The crystallized 2-nitro-phenol is filtered, crushed and rubbed with ice-cooled water in a mortar, filtered again, rewashed with ice-cooled water, and dried at room temperature (6·4 gm., 85 per cent yield. Melting point, 43·5–44·5° C.).

Isolation of 2-nitro-phenol from the mixture of the sodium salts of mono-nitro-phenols. 4·95 gm. of sodium-4-nitro-phenoxide and 10·05 gm. of sodium-2-nitro-phenoxide are dissolved in water, and the solvent evaporated. The dry residual mixture of the sodium salts is extracted with 150 ml. of dry ethanol, stirring for 40 min. at 70° C. It is then cooled to room temperature; filtered, washed successively five times with 20 ml. of ice-cooled dry ethanol and three times with 20 ml. of benzene, and finally with two 10-ml. portions of ethanol. The sodium salt of 2-nitro-phenol dried at 105° C. weighs 8·0 gm. (80 per cent yield). The salt is converted into 2-nitro-phenol by acidification as above. (Melting point, 43·5–45·0° C.)

Electrophoretic Removal of Protein from Hyaluronic Acid

EVIDENCE has been presented[1-3] to show that the hyaluronic acid of ox synovial fluid exists as a complex with a specific protein[4], the latter constituting 25–30 per cent of the total complex. This evidence is, in brief, that hyaluronic acid isolated from synovial fluid by a sufficiently mild means (differential filtration) cannot be obtained free from this amount of protein, and that removal of the protein (as by proteolytic action) from the material so isolated profoundly alters the physicochemical properties of the remaining hyaluronic acid.

It has been claimed, however, by Blix[5] and by Hesselvik[6] using U-tube electrophoresis and by Roseman, Watson, Duft and Robinson[7] using electrodeposition that hyaluronic acid containing substantially less than 25 per cent protein can be isolated; since electrophoresis should be as mild a procedure as filtration, these claims constitute an apparent contradiction of the evidence obtained from filtration experiments. Ogston and Stanier[2], in attempts to repeat Blix's procedure, were unable to obtain hyaluronic acid containing less than 25 per cent protein. Although it has not yet been shown that the products obtained by Roseman, Watson, Duft and Robinson have unchanged physicochemical properties, we have thought it well ourselves to investigate further the removal of protein from hyaluronic acid by electrophoresis.

We were not satisfied that the design of the electrodeposition apparatus[8] was such as to prevent the access of electrode products to the hyaluronic acid. We therefore used an electrodialysis apparatus designed and constructed by Dr. O. Smithies[9]. This apparatus consists of three cylindrical chambers of diameter 3 cm. The end-chambers contain circular platinum electrodes of large area, and the transfer of electrode products to the central compartment (10 ml. capacity) is entirely prevented by a carefully directed flow of fresh buffer through the electrode compartments. The maximum current employed in the apparatus was 40 m.amp., about 5·6 m.amp./cm.². 'Millipore' (Millipore Filter Corporation, Watertown, Mass.) *HA* membranes of pore diameter 0·4μ were used for separating the central compartment from the electrode chambers. The buffer used was 0·025 *M* phosphate, *p*H 7·0. The entire apparatus was used in the cold room at about 2° C.

Preliminary experiments indicated that the 'Millipore' membranes do not permit hyaluronic acid from ox synovial fluid to pass, even under considerable pressure, but do allow the passage of protein. Albumin and γ-globulin were found to migrate freely out of the central compartment with the application of an electric current.

Electrodialysis of ox synovial fluid at about 37 m.amp. caused a rapid loss of protein through the membranes. Colour was almost completely gone at the end of 11 hr. At 14 hr. ultra-violet absorption measurements revealed about 66 mgm. of protein per 100 ml.; at 18 hr., 38 mgm.; and at 22 hr., 23 mgm. At 26 hr. and 30 hr., however, the protein remained at 23 mgm./100 ml. This and another sample of ox synovial fluid, electrodialysed for 36 hr. at 37 m.amp., showed protein contents of 30 per cent of the hyaluronic acid complex.

To confirm this finding, a sample of hyaluronic acid complex prepared by filtration and containing initially 30 per cent protein was electrodialysed for 12 hr. at 37 m.amp. This period was sufficient to remove about 90 per cent of the total protein from synovial fluid, and assuming an exponential loss of protein, approximately the same proportion should have been removed from this material. At the end of the 12 hr., however, the protein content was unaltered. The viscosity and the non-Newtonian variation of viscosity with velocity gradient also remained unchanged.

Since there is reason to think that the protein present in the complex is of normal molecular size[4], and hence that it would, if free, be readily removed through the 'Millipore' membrane (as are all the other proteins of ox synovial fluid, as well as the two serum proteins tested), this evidence suggests that this protein cannot be removed from the complex by simple electrophoresis. Its removal by electrodeposition may have been the result of oxidation or change of *p*H caused by electrode products.

We are grateful to Dr. S. Roseman for unpublished information.

Dextrorotatory Urobilin-IXα and Racemic *d*-Urobilin

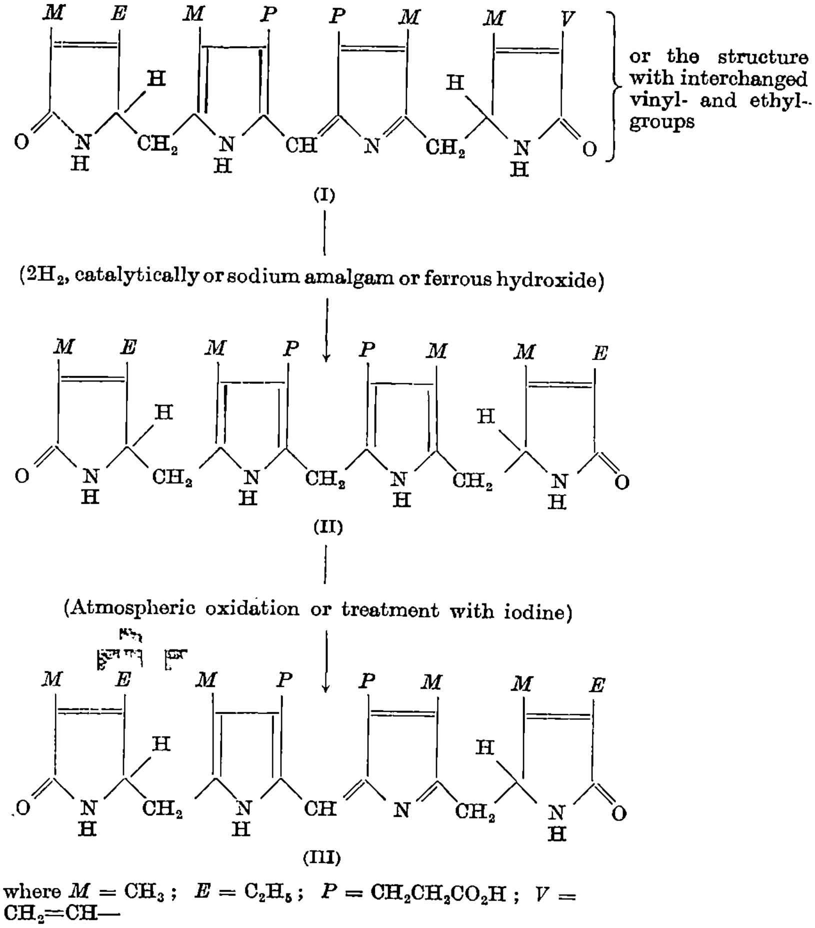
Of the three hitherto known bilene-*b* pigments only *l*-stercobilin and *d*-urobilin are optically active; *i*-urobilin has never been obtained in an optically active form. We now report the isolation of a dextrorotatory urobilin IXα and a racemic form of *d*-urobilin.

d-Urobilin appears to be formally derived from *i*-urobilin by replacement of an ethyl group by a vinyl group[1]. This is in agreement with Watson's earlier observation[2] that sodium amalgam or ferrous hydroxide reduction of *d*-urobilin gives a mesobilirubinogen (II) evidently identical with the compound obtained by total reduction of bilirubin since both afford *i*-urobilin (III) on oxidation. In the presence of colloidal platinum, *d*-urobilin hydrochloride ($[\alpha]_D^{CHCl_3} = +4,390$) in methanol or acetic acid absorbs a maximum quantity of two molecular proportions of hydrogen. However, the leuco-compound thus produced differs from the mesobilirubinogen obtained in Watson's experiments in providing, on oxidation, not *i*-urobilin but a dextrorotatory urobilin of $[\alpha]_D^{CHCl_3}$ = about $+ 4,950$. Quantitative hydrogenation of this pigment shows the presence of only one reducible double bond per molecule (as in *i*-urobilin) and not two (as in *d*-urobilin).

If the structure of *d*-urobilin is that shown in I the new dextrorotatory pigment can only be an optically active isomer of *i*-urobilin. We have recently shown[3] that the order of the β side-chains in *d*-urobilin is that of the IXα pigments; this must also be true of the new dextrorotatory pigment, which we will therefore call '*d*-urobilin IXα'. This accords with the term 'urobilin IXα' which has been given by many workers to *i*-urobilin, although all naturally occurring bile pigments have the IXα structure.

It is difficult to prevent the isomerization of *d*-urobilin to other pigments when the substance is in alkaline solution; but treatment, under hydrogen, with 1·25 *N* sodium hydroxide at laboratory temperature, causes complete racemization in 45 min., about 60 per cent of the pigment remaining as a urobilin. It has been possible to isolate sufficient of the crystalline, racemic urobilin hydrochloride for quantitative hydrogenation; the compound resembles *d*-urobilin but differs from *i*-urobilin in containing two reducible double bonds per molecule.

The existence of an optically active urobilin IXα is of some significance in relation to the structure of the end rings in such pigments. The classical hydroxypyrrole formulæ for *i*-urobilin (IV) and other bile pigments imply the absence of any element of asymmetry apart from that conferred by the asymmetric IXα order of the β side-chains; the substances would not, therefore, be expected to show any significant optical activity. On the other hand, structure III contains two asymmetric carbon atoms so that this structure is more in keeping with the observed optical activity of *d*-urobilin IXα. Doubtless the conditions prevailing in amalgam- or alkaline



(I)

(2H₂, catalytically or sodium amalgam or ferrous hydroxide)

(II)

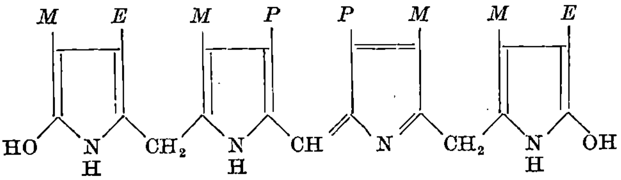
(III)

where $M = CH_3$; $E = C_2H_5$; $P = CH_2CH_2CO_2H$; $V = CH_2{=}CH{-}$



(IV)

ferrous hydroxide reduction of *d*-urobilin are suitable for the racemization of the pigment, and this would explain the formation of *i*-urobilin in Watson's experiments.

d-Urobilin IXα also undergoes racemization in alkali. It is possible that *i*-urobilin, prepared from mesobilirubinogen formed by amalgam reduction of bilirubin, is a true meso compound, but the racemized pigment must contain equal quantities of enantiomorphs. It should therefore be possible to obtain, in addition to the above pigments, a lævorotatory urobilin IXα which is not identical with stercobilin as well as an *l*-dehydro-urobilin IXα which is enantiomorphous with *d*-urobilin.

The quantitative hydrogenations were kindly carried out by Miss J. Cuckney, of the Micro-analytical Department of the Imperial College of Science and Technology.

Excretion of 17-Ketogenic Steroids in Subjects with Complete Transverse Lesions of the Spinal Cord

Elevation of the blood adrenaline-level, whether by intravenous infusion or in response to stress stimuli, leads to an increase in the concentration of adrenocortical hormones in blood[1-4]. It is believed that this increase is mediated by the anterior hypophysis, which responds to the increased blood adrenaline levels by releasing adrenocorticotrophic hormone.

The peripheral blood contains adrenaline, though in very low concentrations, even in the resting state. It has been shown that subjects with complete transverse lesions of the cervical cord have blood adrenaline-levels which are significantly lower than those of normal subjects[5]. More recent work in this Centre has shown that subjects with complete transverse lesions above fifth thoracic vertebra (*T*.5), that is, subjects whose adrenal medullæ are isolated from the control of the higher nervous centres, also show low blood adrenaline-levels.

It was of some interest, therefore, to determine the rate of excretion of adrenocortical hormones in the urine of subjects with complete transverse lesions of the spinal cord above *T*.5. The adrenocortical hormones determined were the 17-ketogenic steroids.

The 24-hr. excretion of 17-ketogenic steroids was determined on 16 male subjects with complete transverse lesions of the spinal cord above *T*.5, and on a comparable group of 17 male subjects with transverse spinal cord lesions complete below *T*.5.

The results are summarized in Table 1.

Table 1. 24-hr. 17-ketogenic Steroid Excretions

Subjects	No. of determinations	Mgm. 17-ketogenic steroids excreted/day (mean ± *S.D.*)
Normals (from Norymberski *et al.* (ref. 6))	8	13·15 ± 3·48
Subjects with lesions below *T*.5	17	14·0 ± 3·19
Subjects with lesions above *T*.5	16	5·8 ± 2·26

For the purpose of statistical analysis, the results of excretion of 17-ketogenic steroids by normal men obtained by Norymberski *et al.*[6] have been used. The results obtained from subjects with lesions complete above *T*.5 are significantly lower ($P < 0{\cdot}01$) than results from subjects with lesions complete below *T*.5 and than from results from normal subjects; there is no significant difference between the results from normal subjects and those from subjects with lesions below *T*.5.

The results are in harmony with the view that adrenaline is concerned in the release of adrenocortical steroids not only in stress conditions but also under resting conditions.

Studies are at present in progress on the plasma 17α-hydroxycorticosterone-levels in subjects with spinal cord lesions. The results of these studies, together with those reported above, will be published *in extenso* at a later date.

Isolation of a New Flavin produced by an Actinomycete

Since the discovery that riboflavin is produced by *Eremothecium ashbyii* and *Ashbya gossypii*[1], a great number of bacteria and fungi have been found capable of producing this and other closely related substances[2]. Among the *Actinomycetales* only a few species of *Mycobacterium*[3] have been reported capable of producing riboflavin, while no true Actinomycete has ever been found to possess such a capacity.

During the isolation of an antibiotic produced by *Streptomyces* 476, a still unidentified species probably belonging to the *griseus* group, a considerable yellow-green fluorescence of the metabolic liquids was noted. The riboflavin potency of such liquids was assayed with mutant strains of *Lactobacillus casei* and *Leuconostoc mesenteroids*, giving an activity corresponding to a riboflavin content of 0·9–1·2 μgm./ml.

The fluorescent pigments could be easily extracted with *n*-butanol and purified by absorption on charcoal and elution with aqueous pyridine. Paper chromatography of such preparations and of the original brews were then run in a *n*-butanol/acetic acid/water system according to Crammer's technique[4]. The

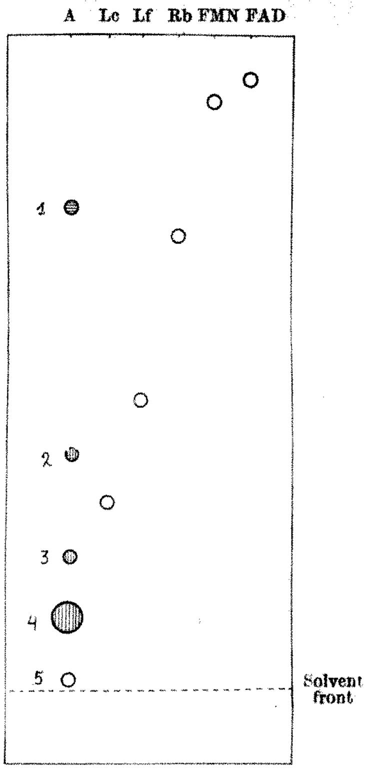

Fig. 1. Paper chromatogram developed with *n*-butanol/acetic acid/water (3 : 1 : 1, v/v). *A*, Sample; Lc, lumichrome; Lf, lumiflavine; Rb, Riboflavin; FMN, flavin-mononucleotide; FAD, flavin-dinucleotide. Areas shaded with vertical lines indicate yellow fluorescence, horizontal lines blue fluorescence and unshaded areas yellow colour without fluorescence

chromatograms showed at least four spots characterized by fluorescence under Wood's light but none could be identified either with riboflavin or its nucleotides or decomposition products (Fig. 1). Only spot 2 reacted with ninhydrin. When the spots were cut off the chromatograms and tested individually, only spot 1, characterized by a blue fluorescence, proved capable of sustaining the growth of *L. casei*.

Further work on the identification of the new flavin is proceeding, and will be reported in detail elsewhere.

Junction of the Epidermis and Dermis

At the surface of the dermis, fine fibres form a continuous subepithelial network[1]. These fibres, unlike the underlying coarser fibres, are argyrophilic and also stain red with periodic acid–Schiff technique[2] (Hotchkiss's method[3]). Into this network, processes from the basal epidermal cells project, and it has been reported that the interlocking of these processes with the dermal fibre is a means by which the epidermis adheres to the dermis[4].

New observations have been made on this junction of epidermis and dermis in the skin of the ox. The skin from the leg of an ox was freeze-dried about 5 hr. after death. Sections (3–5μ) were stained, without preliminary fixation by Foot's silver method[5] (to demonstrate the surface dermal fibres), followed either by Mallory's phosphotungstic acid hæmatoxylin (to demonstrate the tonofibrils of the epidermis) or by periodic acid–Schiff technique (Hotchkiss's method for the presence of mucopolysaccharide).

In the basal layer cells of the epidermis the tonofibrils ran mainly parallel with the long axis of the cell. These tonofibrils were found to project beyond the base of the cell and to pass between the argyrophilic dermal fibres. In Fig. 1*a* the tonofibrils can be seen to pass between the silver-stained dermal fibres.

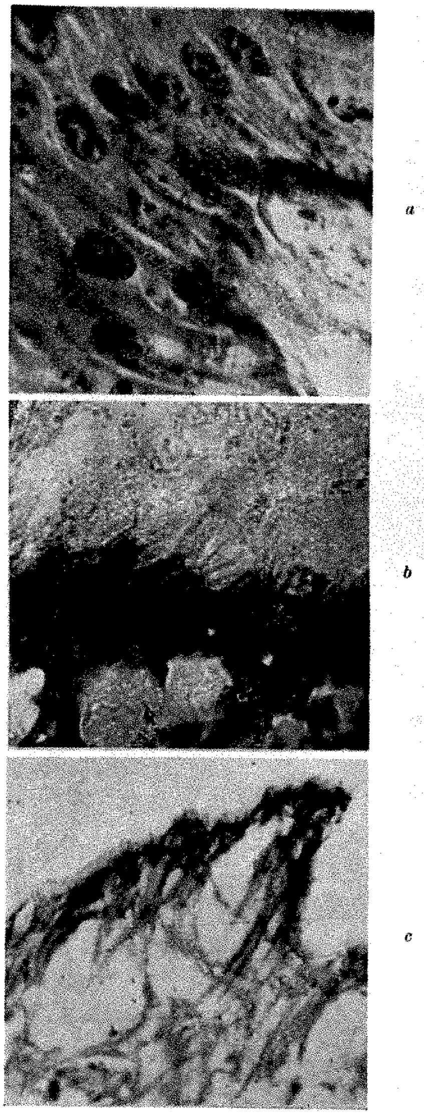

Fig. 1. *a*, Tonofibrils of the basal layer cells of the epidermis interlocking with the silver-stained dermal fibres (× 700); *b*, periodic acid–Schiff-positive fibrils projecting beyond the silver-stained dermal fibres (× 900); *c*, periodic acid–Schiff-positive fibrils as a fringe above the silver-stained dermal fibres (× 530)

From this observation we may conclude that there is also an interlocking of the tonofibrils of the basal cells, and dermal fibres, as part of the system by which the epidermis adheres to the dermis.

Examining the silver-stained sections counter-stained with periodic acid–Schiff reagent, no homogeneous periodic acid–Schiff-positive layer, as reported by Gersh and Catchpole[6], was observed between the dermis and epidermis. However, fine periodic acid–Schiff-positive fibrils were observed to extend from the silver-stained dermal fibres and to project into the epidermis. These fibrils appeared to be continuous with the dermal fibres and to be free ending. They varied in length, the longer fibrils at the tips and base of the papillæ. No epidermal structures were stained in these preparations. Fig. 1*b* shows these fine fibrils projecting beyond the silver stained dermal fibres. Fig. 1*c* shows at a lower magnification the fibrils forming a fringe above the dermal fibres.

Such free-ending periodic acid–Schiff-positive fibrils extending from the subepithelial argyrophilic network have not previously been described. As the fibrils stained intensely with periodic acid–Schiff reagent we may conclude that they are closely associated with mucopolysaccharides, and so it is unexpected that the silver failed to deposit on them. The relationship of these fibrils with the epidermal cells remains to be established.

Enzyme Changes in the Ageing Periosteum

ACID and alkaline phosphatase, cytochrome oxidase and succinic dehydrogenase activities of the periosteum of the femora of 100 normal and 100 traumatized animals were studied histochemically. The animals ranged from newborn to more than one year of age. Trauma was induced by drilling a hole in the midfemoral region.

A steady state of phosphatase activity was revealed in the osteogenic layer of the periosteum of normal animals except for a slight rise at a time comparable to the period of maximum bone formation and a reduction at about the time of sexual maturity. Animals exhibited a rise in dephosphorylating activity throughout the different age groups at the trauma site (Fig. 1, top).

The respiratory enzyme activity of the periosteum of normal animals was high at birth and increased at five weeks; a drastic reduction, however, was observed in all the older animals. At the site of trauma an increase in respiratory enzyme activity occurred but to a lesser degree with increasing age of the animal (Fig. 1, bottom).

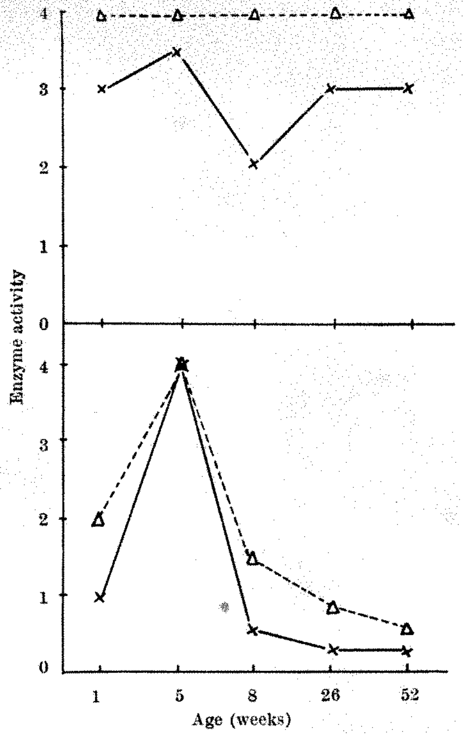

Fig. 1. Enzyme activity based on intensity of precipitate and colour in the osteogenic layer of the periosteum of rat femora taken at different ages. ×, Normal periosteum; Δ, traumatized periosteum. Top, phosphatase activity; bottom, respiratory enzyme activity

Zorzoli[1] has reported an increase in acid phosphatase activity in the cells of old animals. Weinbach and Garbus[2] have shown that in the liver and brain of old animals the respiratory level was maintained. This was supported by Bourne[3]. Bourne[4] further indicated that there was evidence of some increase in cytochrome oxidase and succinic dehydrogenase activity in the tissues of older animals.

It appears that, at least in the periosteum of rats, phosphatases do not increase with ageing, and the respiratory enzyme activity decreases to a low level. This is further supported in the observation that the cells of the periosteum of traumatized animals are less able to increase their respiratory enzyme activity with increasing age to levels seen in younger animals.

Bourne[3] states that the consequence of dephosphorylation of metabolically important substances may be behind the fundamental processes involved in cellular senescence. Trauma to bone at any age leads to increased dephosphorylation which is essential for bone repair mechanisms. This brings renewed life to an injured area. The respiratory enzymes, however, are associated with the reactions which make energy available to cells for various activities. The reduction in the activity of these enzymes is believed to be involved with cellular changes which bring about the gradual disappearance and death of the osteoblasts, which in turn reflect a reduction in bone repair rate and growth with increasing age.

The present results will be published elsewhere in greater detail.

Ovaries of Some Fœtal and Prepubertal Giraffes (*Giraffa camelopardalis* (Linnæus))

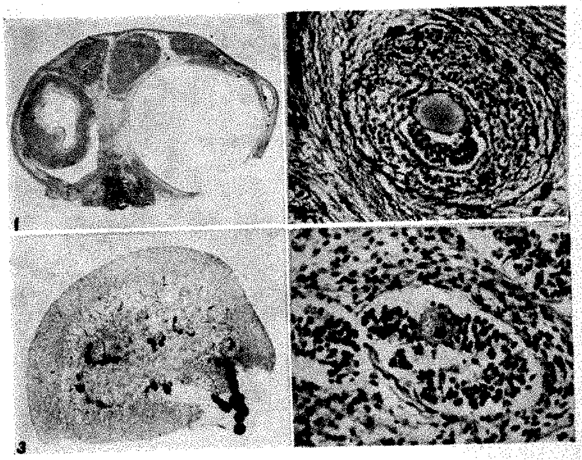

Fig. 1. (1) Section of a late gestation giraffe fœtal ovary showing luteinization, and advanced follicular development (× *c.* 1·5); (2) reticular fibres and capillary vessels penetrating a mass of granulosa-like cells which surround a centrally placed ovum (× *c.* 85); (3) section of a mid-gestation giraffe fœtal ovary showing a wide cortical region separated from the central medullary core by a zone of connective tissue which contains relatively few sex cells (× *c.* 4); (4) rete ovarii with contained ovum from a mid-gestation giraffe fœtal ovary (× *c.* 160)

In several species of mammals the ovaries of near-term fœtuses show a departure from the typical pattern of development as known in the laboratory rodents, the cat, the dog, etc. Deviations from this normal have been described in the fœtal gonads of the horse[1], the seal[2] and the African elephant[3], in which species an enormous development of interstitial cells is a characteristic feature. A premature development of large ovarian follicles, with antrum formation and luteinization, has been described in the human full-term fœtus[4-9]. Follicle development up to antrum formation appears to be a constant occurrence in the ovaries of near-term fœtal sheep (personal observations), and can occur in the cow[8]. The morphogenesis of the giraffe fœtal gonads provides yet another example of a departure from the normal pattern.

We have examined three stages in the development of the gonads of the female giraffe. So far as we can ascertain, these represent the mid-gestation, late-gestation and new-born periods. In many respects the histological structure of the ovaries of the late-gestation specimen *C.R.* = 1,040 mm. (at birth approximately *C.R.* = 1,162 mm.), Fig. 1,1, recalls that of an adult mammal. The germinal epithelium is cuboidal, there is a well-developed definitive tunica albuginea containing an abundance of both collagen and reticular fibres, the primary follicles are relatively few in number, and many appear shrunken and degenerate. In the medulla there are a number of apparently normal follicles, some of which have a large antrum and a well-developed discus proligerus; the largest is illustrated in Fig. 1,1. Hæmorrhagic follicles of various sizes are present in both ovaries as well as a number of corpus luteum-like structures (Fig. 1,1). These latter are solid, spherical bodies well vascularized and surrounded by a theca externa. The luteinized cells are of two types easily distinguished by their staining affinities, in sections stained in hæmatoxylin and eosin, and also by their size. It is of interest, therefore, to find that in all the adult giraffe ovaries so far examined by us the luteal cells of the corpora lutea of pregnancy show a similar dimorphism. Moreover, in the corpora lutea of pregnancy the proportion of large to small luteal cells appears to reflect the age of the structure. The impression is gained that in the fœtus the luteal bodies are of two forms, one in which the small cell type is prominent and a second in which it is less conspicuous. Besides these solid structures, there is what appears to be a luteinized follicle with a large central cavity (Fig. 1,1).

In the medullary stroma of the fœtal ovary of late gestation, a few discrete, spherical masses of granulosa-like cells surrounding a centrally or eccentrically placed oocyte are also present. These structures are penetrated by large sinusoidal capillary vessels, and contain a conspicuous network of reticular fibres (Fig. 1,2). In the ovaries of two mid-term fœtuses (*C.R.* = 485 mm. and *C.R.* = 620 mm., respectively), these last-mentioned structures, together with what appear to be normally developing follicles, are prominent features in the medulla, and in some of the follicles antrum formation has begun. In the older of the two specimens there is one exceedingly large hæmorrhagic follicle and several smaller ones. No such structures are present in the younger specimen. Surrounding the centrally placed follicles in both specimens and separating them from the cortex is a prominent zone of connective tissue (Fig. 1,3). The cortex of both ovaries is wide, and consists largely of closely packed primary follicles embedded in a small amount of connective tissue. The germinal epithelium, in the few places where it is undamaged, is simple and cuboidal. Lying immediately below, and penetrated in most places by connective tissue elements, are epithelial cells and a small number of sex cells not yet in the primary follicle stage. A few of the innermost of the cortical primary follicles appear to have penetrated into the subadjacent connective tissue zone, and even into the more centrally placed medullary core. There are signs of degeneration in many of the oocytes both in the primary follicles of the cortex and in the primary and more advanced follicles of the medulla.

Whether the spherical masses of granulosa-like cells penetrated by capillaries and surrounding an oocyte, which are so striking a feature of the medulla in the mid-term ovaries, are derived from a current cortical proliferation or are medullary derivatives is not yet clear. In places these structures occur in the neighbourhood of, and are closely associated with, the rete ovarii, the cells of which are separated, in places, by the occurrence of germ cells of various sizes (Fig. 1,4).

The ovaries of the two new-born giraffe specimens in our collection both contain large apparently healthy follicles with antra, large luteinized follicles, and numerous corpus luteum-like structures. These findings, together with the observations of a broadly similar picture in the ovaries of older prepubertal specimens, suggest that the developmental stages we have outlined above are a normal feature of ovarian development in this species.

The endocrinological implications of some of these findings, particularly as they are related to the fœtal gonads of late gestation, have been discussed by Amoroso[10-12]. From the foregoing observations on the giraffe fœtal gonads, and others we have made on the fœtal reproductive tracts, it seems clear that both are sensitive to hormonal stimulation for some time before birth, and, as gauged by the histological appearances, the fœtal ovary of the giraffe may be capable of adult secretory functions in addition to gametogenic functions. In view of the similar character of the ovarian changes in the human and giraffe ovary at birth, the occurrence of gonadotrophins in the urine of pregnant giraffe[13] becomes a matter of special interest. On the other hand, it is possible to envisage an endocrine picture in which maternal (or placental) œstrogen acting directly, or indirectly through the fœtal pituitary, plays a dominant part.

Avoidance of 'Secondary Disease' in Radiation Chimæras

In the experience of this laboratory the radiation chimæras[1], produced by irradiating *CBA* mice with 950 rads of X-rays and then injecting them intravenously with bone marrow from $C_{57}BL$ mice, invariably die within 4 months from 'secondary disease'. Congdon *et al.*[2] have worked on the lines that this condition might be due to recovery of the host animals' capacity to eliminate the foreign graft. We[3] and Uphoff[4] have favoured the idea that it was due to reaction by the graft against the host.

To test the latter hypothesis with its corollary that material from immature donors may be less reactive, similar irradiated *CBA* mice (950 rads of X-rays ; 250 kV. constant potential, 15 m.amp., half-value layer 1·2 mm. copper, 43 rads/min. at 70 cm.) have been given myeloid tissue from fœtal and newborn $C_{57}BL$ mice with the following results (Table 1).

Table 1. Survivors of Irradiated *CBA* Mice (950 rad X-Rays) given Myeloid Tissue from $C_{57}BL$ Mice

Myeloid tissue given	Survivors at 120 days
(*a*) Adult bone marrow	0/30
(*b*) Newborn spleen	11/20
(*c*) Embryo spleen	9/15
(*d*) Embryo liver	4/10

Two of the survivors in group (*b*) and seven of those in group (*c*), when they had survived more than three months and were in good condition, were grafted with skin from $C_{57}BL$ mice of the same stock. One animal died (? pylephlebitis) during the procedure of deplastering, one skin graft was shed after ten days ; the other seven grafts were intact after 2 months.

These results are in accord with our original hypothesis.

Transformation of Megaloblasts to Normoblasts by cultivating Human Bone Marrow in Presence of Vitamin B_{12} and Vitamin B_{12}-binding Protein

Callender and Lajtha[1] observed that little or no conversion of megaloblasts to normoblasts occurred when pernicious anæmia marrow was cultivated in pernicious anæmia serum by itself or together with vitamin B_{12}. However, if bone marrow is cultivated in pernicious anæmia serum containing vitamin B_{12} and normal gastric juice or in normal serum with vitamin B_{12} megaloblasts are partly converted into normoblasts within twenty-four hours. Swan *et al.*[2] did not find this influence of vitamin B_{12} and gastric juice, but Astaldi and Cardinali[3] have recently confirmed the findings of Callender and Lajtha[1].

We cultivated human megaloblastic marrow in suspension in pernicious anæmia serum or in normal human serum as described by Osgood[4] and Lajtha[5], and were able to confirm the findings of Callender and Lajtha[1] and Astaldi and Cardinali[3].

It seems that the effective principle in gastric juice and normal human serum necessary for the activity of vitamin B_{12} in the conversion of megaloblastic marrow to normoblastic marrow is the vitamin B_{12}-binding protein. By zone electrophoresis or fractionation with ammonium sulphate we prepared vitamin B_{12}-binding protein from normal gastric juice. When this was added to the bone-marrow cultures together with vitamin B_{12}, the conversion of megaloblastic marrow to normoblastic marrow showed decisive improvement. In some of these cultures we found 50 per cent of the nucleated red cells as normoblasts after twenty-four hours. In the same cultures containing only vitamin B_{12} there were no normoblasts at all. Bone marrow cultivated in normal human serum with vitamin B_{12} contained about 10 per cent of the nucleated red cells as normoblasts after twenty-four hours. The effect was not achieved when some other protein of gastric juice, having no binding capacity for vitamin B_{12}, was added to the cultures. Due to its binding capacity for vitamin B_{12} the α-globulin fraction of normal human serum also showed a marked effect on the conversion.

These investigations were performed on bone-marrow cultures of nine patients with pernicious anæmia in relapse and all yielded the same results.

Further particulars of this work will be published elsewhere.

Occurrence of Foldings of Plasma Membrane (β-Cytomembrane) in Cells of Pig's Carpal Organ as revealed by Electron Microscopy

THE carpal organ of the pig is a conglomerated sweat gland, and histologically it is known to be similar to the usual small sweat gland (eccrine gland)[1]. This organ is useful for investigating the fine structure of sweat glands with the electron microscope, since the conglomerated body of the gland is easily seen with the naked eye and most of the glandular tissue is found within the small field of the electron microscope. The tissue was fixed in 1 per cent osmic acid and buffered at *p*H 7·4 with acetate–veronal or phosphate buffer, washed for a short time and then dehydrated with ethanol in a graded series of concentrations. The specimens were embedded in a mixture of *n*-butyl and methyl methacrylate (7 : 3), and were cut into sections less than 0·05μ thick with a thermal expansion microtome (*JUM*-4) fitted with a glass knife. Embedded sections were examined in a *JEM*-3 electron microscope.

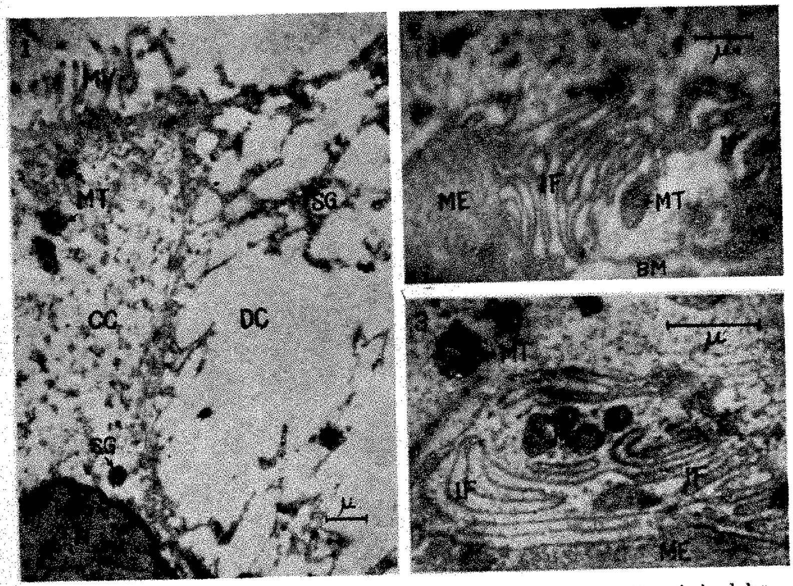

Fig. 1. An electron micrograph of apical and intermediate zone of two adjacent glandular cells (*CC*, clear cell; *DC*, dark cell). *MV*, microvilli; *MT*, mitochondria; *SG*, secretory granules; *N*, nucleus. Figs. 2 and 3. Electron micrographs of nasal portion of the glandular cell, showing the elaborated infolding (*IF*) of basal plasma membrane. *MT*, mitochondria; *ME*, myo-epithelial cells; *BM*, basement membrane

The presence of two kinds of glandular cells in the secretory portion of eccrine sweat glands has already been demonstrated by light microscopy in both human and certain mammalian skins, as well as in the carpal organ of the pig[1–3]. Dark cells, which are observed with the light microscope to contain a number of secretory granules stainable with iron-hæmatoxylin and are periodic acid–Schiff positive, show a number of large electron-lucent vacuoles, which may correspond to the dark-stained granules seen with the optical microscope. While the cells which are clear in light microscopy are rather dark under the electron microscope, secretory granules of this cell type were seen as relatively small, extremely dense granules (Fig. 1).

The free surface of both types of cell is covered by microvilli which are rather irregular in shape when compared with those of the brush or striated border seen in the proximal convoluted tubule of the kidney or intestinal epithelium. The development of microvilli is less marked on the dark cells than on the clear cells (Fig. 1). This was also observed with the light microscope[1].

In the basal cell zone and the lateral boundaries of both cell types, complicated foldings of the plasma membrane were observed (Figs. 1, 2 and 3); this is analogous to the structure called the "β-cytol membrane" by Sjöstrand[4]. The folding at the lateral cell margin is less developed than that of the basal one. The folding in the basal cell zone facing the myoepithelial cell or the basement membrane is similar to the basal infoldings observed in the proximal convoluted tubule of the kidney, the epithelium of the duct of some salivary glands, ependymal cells of the choroid plexus, and in the ciliary body of the eye, all of which are thought to be closely associated with water transport[5]. This suggests that these cells are also associated with the active transport of water from the surrounding connective tissue and blood capillaries into the lumen of the gland producing the sweat, that is, the dilution of the secretory product.

The α- and γ-cytomembranes[4] (called the rough and smooth surfaced varieties of endoplasmic reticulum by Palade[6]; the latter is also identical to the Golgi complex of Dalton[7]) as well as mitochondria are also contained in both glandular cell types. The features corresponding to the various states of the secretion cycle will be described elsewhere.

Physical Release of Acetylcholine from the Thoracic Nerve Cord of *Periplaneta americana* L.

Recently, suggestions have been made that acetylcholine in nerve tissue is associated with structural entities termed 'vesicles'[1]. The ideas are compatible with a quantum concept of nerve transmission[2]. The evidence that acetylcholine is released from mammalian nerve tissue by physical means[3] lends further support to the structural inclusion of acetylcholine within the nerve cell and casts doubt on the hypothesis that it is held in chemical combination. The following results on the release of acetylcholine from cockroach thoracic cord by osmotic pressure and homogenization makes the existence of a chemical combination in insects doubtful.

Table 1. Effect of Osmotic Pressure on Amounts of Acetylcholine in Supernatant and Residues of Homogenates of Cockroach Thoracic Cord

Extraction molarity with medium homogenization (17 sec.)	Acetylcholine			
	Total (μgm.) (15 cords)	Supernatant (μgm.)	Residue (μgm.)	Supernatant (per cent)
Distilled water	5·75	4·75	1·0	82·6
0·244 *M* Ringer	4·57	3·18	1·39	69·5
0·314 *M* Ringer	4·68	2·85	1·83	60·8

The results in Table 1 show the effect of extraction media of different osmotic pressures on the amounts of acetylcholine recovered from supernatants and residues of homogenates of thoracic cords of cockroaches. The cords were homogenized for 17 sec. in ice-cold medium and centrifuged at 50,000*g* for one hour. Assays for acetylcholine were carried out on frog rectus abdominus muscle, and the values are expressed as chloride. It is clear that both the supernatant and residue values for acetylcholine depend upon the tonicity of the extraction medium. The relatively hypertonic medium, 0·314 *M*, which gave the lowest supernatant value, has the equivalent osmotic pressure of Hoyle's insect Ringer. Furthermore, desheathed cockroach ganglia do not swell at this osmotic pressure. Having established an extraction medium apparently suitable to this insect nerve tissue a combination of homogenization and osmotic pressure was employed to release acetylcholine. The results are shown in Table 2. It is striking that the hypotonic medium, distilled water, released a high proportion of acetylcholine into the supernatant, whatever the severity of homogenization. In the instance of the hypertonic medium more acetylcholine was released into the supernatant with increasingly severe homogenization, until the value for acetylcholine in the supernatant approximated that of distilled water. It should be noted that in either medium it was not possible to obtain all the acetylcholine in the supernatant at severe homogenization.

Table 2. Effect of Homogenization and Osmotic Pressure on Amounts of Acetylcholine in Supernatants and Residues of Homogenates of Cockroach Thoracic Cord

Degree of homogenization	Acetylcholine							
	Distilled water				Insect Ringer 0·314 *M*			
	Total (μgm.) (15 cords)	Supernatant (μgm.)	Residue (μgm.)	Supernatant (per cent)	Total (μgm.) (15 cords)	Supernatant (μgm.)	Residue (μgm.)	Supernatant (per cent)
Light (5 sec.)	5·85	4·35	1·5	74·3	5·43	2·9	2·53	53·4
Medium (17 sec.)	5·75	4·75	1·0	82·6	4·68	2·85	1·83	60·8
Waring blendor (1 min. at 16,000 r.p.m.)	5·5	4·5	1·0	81·8	5·05	3·3	1·75	65·3
Medium + Waring blendor	4·65	4·28	0·37	92·0	4·52	3·86	0·66	85·4

It is concluded from these results that acetylcholine in cockroach thoracic cord can be released by both osmotic pressure and mechanical disruption. The ease with which acetylcholine can be released in insects supports the suggestion that in insects it can be released more easily than in mammals (Pal, R., unpublished). The evidence favours the hypothesis that acetylcholine is not in chemical combination in insects but located in the nerve cell within a 'structural compartment'.

Method of isolating the β_1-Metal-combining Globulin from Human Blood Plasma

Surgenor, Koechlin and Strong[1,2] have described the isolation of the β_1-metal-combining globulin (siderophilin, transferrin) from Cohn's plasma fraction IV–4 by alcohol fractionation. The crystallization, described by Koechlin[2], could not easily be reproduced by other investigators. Improved conditions for the purification and the crystallization starting from fraction IV–7 have recently been published by Inman[3]. Already the preparation of fraction IV–7 requires many steps and much time, which may be one of the reasons why only very few clinical experiments with this iron-transmitting globulin have been reported.

We have found that an electrophoretically almost pure preparation of the metal-binding globulin can be obtained by a much shorter procedure using rivanol (2-ethoxy-6,9-diaminacridinelactate).

Hořejši and Smetana[4] have shown recently that rivanol precipitates from serum or plasma at *p*H 7·3 almost all the proteins except the γ-globulin (2 parts of plasma + 7 parts of 0·4 per cent rivanol solution at room temperature). After adsorption of the rivanol by charcoal, the γ-globulin can be precipitated from the supernatant in very good yield under conventional conditions.

We have found that the supernatant of the rivanol precipitation contains significant amounts of albumin and a highly soluble β-globulin besides γ-globulin. The higher the *p*H during the rivanol precipitation, the smaller are the amounts of albumin found in the supernatant. Between *p*H 8 and 10 albumin is precipitated almost quantitatively, while the supernatant still contains γ-globulin and the soluble

β-globulin. From the rivanol-free solution the γ-globulin is precipitated in the presence of 25 per cent ethanol at pH 6·8 ($-6°$ C.), whereafter the β-globulin is carried down by 40 per cent ethanol at pH 5·8. Further purification of the β-globulin can be achieved by dissolving it at pH 9·4 (4–6 per cent protein) and repeating the rivanol procedure. From 100 gm. plasma proteins about 2 gm. of β-globulin almost pure paper-electrophoretically were obtained.

The deep red-brown colour of the solutions of this β-globulin fraction is characteristic of the iron-combining protein. Normally it is only partly saturated with iron. By dialysis against versene (ethylenediaminetetraacetate) it can be freed from iron and thereby becomes colourless. Quantitative determinations of the iron-binding capacity have shown that the preparations obtained in this simple manner consist to about 90 per cent of metal-combining globulin. So far as their purity is concerned, these preparations therefore correspond to fraction IV–7–2.

We think that the high solubility of the β_1-metal-combining globulin in the presence of rivanol above pH 7 makes this reagent a very suitable tool to prepare larger amounts of this interesting protein for clinical experiments.

Details of our studies, which are being continued, will be published later.

Soluble Antigens in Microsomes and Other Cell-Fractions of Rat Liver

It has been known for some time that particulate material sedimentable by high speed from tissue cells has characteristic immunological properties, and the antigenic specificity of isolated cell fractions has been studied in a variety of normal and tumour tissues[1]. These investigations not unexpectedly revealed a high degree of antigenic complexity of the different cell fractions, making further analysis difficult by the methods at hand. However, the results seemed encouraging enough to warrant an extension of the immunological work to the various soluble antigens characterizing different parts of the cell. An investigation of this sort has been carried out in our laboratory, and a detailed report of it will be published later.

The work was carried out on mitochondria, submicroscopic particles and supernatant prepared from liver cells of adult normal rats. For immunization, perfused livers were homogenized in 0·25 M sucrose and fractionated by differential centrifugation. Some microsome samples were prepared by the method of Palade and Siekevitz[2]. For control purposes, antisera were prepared also against total homogenate made in 0·9 per cent saline and against rat serum. The concentrated samples were injected as soon as possible after isolation. The antisera were obtained in rabbits using adjuvant techniques for injection.

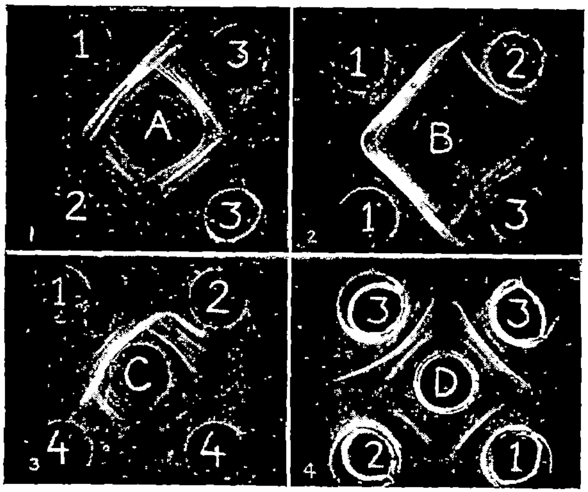
For testing, the cell fractions were prepared similarly, but variations in the conditions of fractionation were studied as separate variables. Mitochondria and microsomes were extracted with 0·4 per cent deoxycholate[2] and the microsomes were further fractionated by means of additional extractions with versene. Since the deoxycholate did not affect the reactivity of the antigens, the extracts could be used for testing without further treatment. The supernatants were tested directly in sucrose or after pressure dialysis against 0·9 per cent saline. Protein and ribonucleic acid determinations were always carried out in order to test the efficacy of the fractionations.

The double diffusion agar-techniques according to Korngold[3] were used in the immunological experiments. Instead of penicillin-cups, small plastic cups with a closed base and with narrow openings close to the base were used as containers for the reagents. The agar layers were poured into Petri dishes on the top of a thin glass slide. The experiments were run at 37° or at 4° C.; one or two fillings were sufficient to ensure strong reactions. After completion of the reactions in the refrigerator, the plates were washed, dehydrated with ethanol, stained and finally dried[4]. The glass slides with the thin agar film on top were removed from the dishes, and the preparations were mounted with liquid plastics under a second slide of the same dimensions[5].

The precipitation patterns obtained in the experiments were often complex and difficult to interpret. The criteria used for identification of the antigens and antibodies were those commonly applied in the Ouchterlony procedure[6]. Our conclusions are based on only those results which could be confirmed by means of independent experimental procedures, including, for example, reciprocal testing, tests at different antigen/antiserum ratios and chemical fractionations of the antigen solutions.

The antisera against both total homogenate and the cell fractions contained only small amounts of antibodies reacting with the proteins of rat serum. Correspondingly, the amount of these antigens in the cell fractions was mostly negligible. In fact the reactions showed an unexpectedly high degree of 'cell-fraction'-specificity. As a general rule, supernatant and deoxycholate extracts of mitochondria and microsomes gave the strongest and most complex precipitation patterns with their homologous antisera (Figs. 2–4). Entirely confirmative results were obtained with the anti-total homogenate sera (Fig. 1). The microsomes were 'strongest antigenic', probably due to lesser stability of both the mitochondrial preparations and the supernatants. This report deals mainly with the immunological properties of the microsome preparations.

The deoxycholate extracts of the microsomes were characterized by a group of antigens, occurring abundantly and predominating also as antibody producers (Fig. 2). The minimum number of detectable antigenically different molecules within this group was five. There are reasons for believing that these antigens, which we may call 'D-antigens', constitute an important part of the proteins extractable with deoxycholate from the endoplasmic reticulum of the hepatic cells[2].



Figs. 1–4. Antisera: *A*, anti-total homogenate; *B*, anti-microsomal; *C*, anti-mitochondrial; *D*, anti-supernatant. Antigen solutions: 1, deoxycholate extract of microsomes; 2, deoxycholate extract of mitochondria; 3, supernatant; 4, rat serum

Whereas the supernatants were essentially free from these D-antigens, the situation was more complicated for the mitochondria. Thus, the anti-mitochondrial sera contained a certain amount of antibodies reacting with the D-antigens in the microsomal extracts, but the concentration of the antibodies was lower here than in the anti-microsomal sera. Apart from antigens characteristic of mitochondria only, deoxycholate extracts of the mitochondria contained D-antigens in relatively small amounts (Fig. 3), varying from preparation to preparation. This might indicate that the presence of the D-antigens in the mitochondrial preparations was due to contamination with endoplasmic reticulum[7], although thus far other explanations cannot be excluded.

Apart from these D-antigens, the deoxycholate extracts of the microsomes contained an additional number of antigens in common with supernatant, and reacting with antibodies in both anti-microsomal and anti-supernatant sera (Fig. 4). In contrast to what has been found for the D-antigens, the distribution of these antigens between the microsome fraction and the supernatant was highly dependent on such variables in preparation as time and speed of centrifugation, sucrose concentration, washing, etc.

Versene extracts of the microsomes contained relatively little in common with the deoxycholate extracts. A certain number of distinguishable antigens, occurring in small amounts and generally not detectable in the deoxycholate extracts, could be found when these extracts were allowed to react with anti-supernatant serum. It cannot yet be stated whether these antigens represented contaminating proteins derived from the supernatant or whether they were common to both fractions in a more functional sense.

Naturally, a considerable amount of work remains to be done for a complete characterization of the main soluble antigens of the liver cell. However, the results reported here are sufficient to show that the striking differences between the antigens make it possible to analyse the cell fractions by the methods described above. Hence, in combination with common biochemical techniques, these methods should offer a valuable tool for testing the efficacy of a cell-fractionation procedure. Furthermore, they seem particularly well suited for a study of the genetic relationship between different elements of the liver cell. Finally, it should be pointed out that a combination of the immunological techniques with work on the incorporation of isotopes should be particularly suited for an investigation of such problems as protein synthesis *in vitro* in isolated cell fractions. Studies along these lines are in progress.

We are indebted to Dr. T. Hultin for valuable discussions and advice.

Variations in the Erythrocyte Potassium and Sodium in the Possum, *Trichosurus vulpecula*

The ratio of the concentration of sodium ions to that of potassium ions in erythrocytes has been recorded for numerous animal species. In most cases, the relation between the concentrations of sodium and potassium is of the same order for individuals of any one species[1]. This uniformity between individuals, however, does not exist in sheep. Evans[2] has summarized the previous work on sheep, and his own results show three distinct types of sheep, according to the concentrations of potassium and sodium in the erythrocytes, in the various breeds he examined. Evans and King[3] had already shown that variations in concentrations of these ions in sheep erythrocytes were determined by a single-gene substitution.

There has so far been no demonstration of similar variations in any wild population of animals. The results presented here show marked variations in the erythrocyte concentrations of sodium and potassium between individuals of a marsupial, the brush-tail possum, *Trichosurus vulpecula*.

The animals used were trapped in the suburbs of Perth, Western Australia, and of Adelaide, South Australia. (Samples from Adelaide were kindly sent by Mr. J. Eadie, Department of Zoology, University of Adelaide, South Australia.) Blood was collected by heart puncture into heparinized syringes. The Perth samples were treated as follows: for indirect estimation of ionic concentrations in the erythrocytes from whole blood and for plasma values, a portion of the whole blood was separated soon after collection, the remainder was centrifuged and the plasma decanted immediately; the cells separated by

Table 1. COMPARISON OF DIRECT AND INDIRECT METHODS FOR EVALUATION OF CONCENTRATIONS OF SODIUM AND POTASSIUM IONS IN ERYTHROCYTES FOR TWENTY-SEVEN PERTH POSSUMS

Group	No. of animals	Sodium (m.equiv./l.)			Potassium (m.equiv./l.)		
		Cells		Plasma	Cells		Plasma
		Direct method	Indirect method		Direct method	Indirect method	
High $[K^+]$	7	36·3	36·8	157·2	103·8	101·2	5·9
Low $[K^+]$	20	129·6	124·7*	160·7	10·3	10·9*	5·7

* Mean value for sixteen animals only.

centrifugation were prepared for direct estimation of the concentrations of sodium and potassium ions by three washes with isotonic glucose and then resuspended in isotonic glucose for hæmatocrit estimation. Cell samples sent from Adelaide were prepared by two washes with isotonic sucrose after preliminary separation of plasma, followed by 1 : 1 dilution of cells with distilled water. Hæmatocrit estimations were made in duplicate or triplicate using metal-sheathed micro-tubes spun at 3,000 r.p.m. for 30 min. ; concentrations of sodium and potassium ions were determined with an EEL flame photometer.

The concentrations of sodium and potassium ions in the erythrocytes of 42 possums (27 from Perth, 15 from Adelaide) determined by the direct method are plotted in Fig. 1. There is a clear-cut division of the animals into two groups, one with a high concentration of potassium and a low concentration of sodium in the erythrocytes (21 animals) and the other with a low concentration of potassium and a high concentration of sodium in the erythrocytes (21 animals). Some of the Western Australian possums were sampled repeatedly over periods up to three months. The variations between samples from the same animal were small compared with differences between the two groups. The mean sum of the concentrations of the two ions for individuals is approximately 30 m.equiv./l. lower in the Adelaide sample than in the Perth sample. This can probably be accounted for by differences in the preparation of the cell samples from the two areas.

Table 1 records the mean concentrations of sodium and potassium ions for the two groups of the Perth sample, determined by the direct and indirect methods, which give results in close agreement.

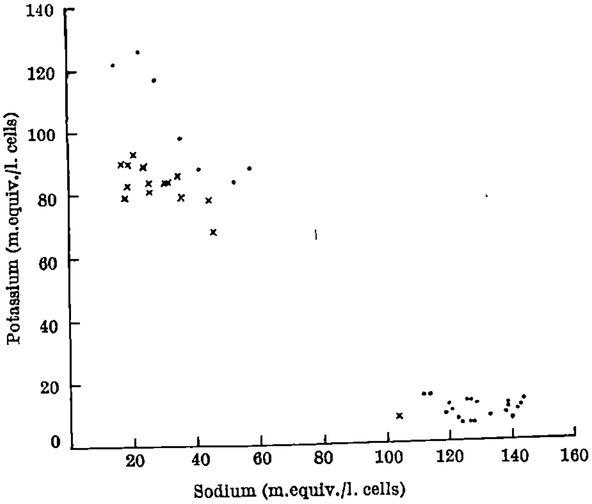

Fig. 1. Erythrocyte concentrations of sodium and potassium ions for 27 Perth possums (●) and 15 Adelaide possums (×), each point representing one animal

The animals from Perth and Adelaide constitute samples of two geographically isolated populations. The ratio of animals exhibiting a high concentration of potassium to animals exhibiting a low concentration of potassium is quite different in the samples from the two areas, being roughly 1 : 3 in the Perth sample and 14 : 1 in the Adelaide sample. The frequency of the different types of sheep varies with breed and geographical distribution[2], and it will be of interest to see what frequencies of cell types occur in possum populations in areas of Australia not so far sampled.

The two cell types reported here for the possum correspond most closely to the Evans α- and γ-types in sheep. Breeding experiments are in progress to determine whether genetic differences are responsible for the different types of erythrocyte in the possum.

The possibility of there being different types of hæmoglobin in the possum, as in the sheep[4], was suggested by Mr. R. L. Kirk (Department of Zoology, University of Western Australia), who has so far tested samples from fourteen of the Perth possums. No differences in type of hæmoglobin have been observed in this preliminary investigation.

Reproduction of Fused Larvæ in the Boring Sponge, *Cliona celata* Grant

LARVÆ of the sponge *Lissodendoryx carolinensis* fuse with each other if brought together in culture dishes, and some of the compound larvæ metamorphose[1]. Nevertheless, one would rarely expect such an event in Nature, as most sponge larvæ are released a few at a time, and disperse rapidly. In *Cliona celata*, however, I have observed successful reproduction by fused larvæ in a much more natural environment than a culture dish.

Throughout the summer of 1955, I kept several oyster shells containing boring sponges in an asphalt-lined wooden aquarium through which seawater constantly flowed. The water was pumped from the bottom of the Bideford River, Prince Edward Island, an estuary in which *Cliona* was growing, and did not change appreciably in temperature or lose suspended matter during its passage to the aquarium. *Microciona prolifera*, a sponge much more sensitive to stale water than *Cliona*, lived indefinitely and reproduced freely in a similar tank.

Under these conditions, *C. celata* (which is oviparous) may discharge tens of thousands of eggs from a large osculum in a few hours. The eggs are sticky, and adhere to each other and to the substratum in an irregular flattened mass. Diatoms, the shells of larval molluscs, silt and other debris rapidly accumulate on and in the mass, so that on hatching many of the larvæ are temporarily trapped, able to wander among the interstices of the egg mass but delayed in their escape to open water. In their wanderings, the larvæ sometimes come together in twos or threes and fuse. Fusion is without apparent regard for polarity, so the swimming movements of compound larvæ are often merely ineffective gyrations and many perish within the tangle of debris. A few escape, however, since two such compound larvæ metamorphosed successfully into single sponges, with single oscula, and began boring in crystals of calcite placed near an egg mass.

It seems quite possible, then, that *Cliona* larvæ occasionally metamorphose after fusion, in their normal environment. The natural occurrence of larval fusion, previously dismissed as a purely experimental phenomenon, emphasizes its interest to students of individuation and related problems of theoretical morphology.

This observation is part of a study of *Cliona* conducted at the Fisheries Research Board of Canada's Biological Sub-Station at Ellerslie, Prince Edward Island, which will be more completely reported elsewhere. I thank other members of the Sub-Station staff for their help.

Pressure developed within the Reticular Compartment of the Ruminant Stomach

In order to investigate the mechanical aspects of digestion in the ruminant stomach, pressure variations occurring within the reticulo-rumen have been measured on many occasions[1–3], using balloons connected to liquid-filled manometers or to recording tambours. Wester[1] reported that the intra-ruminal pressure in the cow showed phasic fluctuations of 2·5 cm. mercury, while Quin, Van der Wath and Myburgh[2] recorded a maximal rise of 10·0 cm. water in the sheep; in both instances the basal intra-ruminal pressure was close to atmospheric pressure. Balch, Kelly and Heim[3], using a balloon connected to a writing tambour, recorded pressure-changes from within the reticulum of the cow and showed a basic level of 2·5–3·5 cm. mercury above atmospheric pressure rising by 1–2 cm. mercury with contraction of the reticulum. It is probable that in the latter case the higher resting pressure is due to the hydrostatic effect of the liquid contents of the reticulum.

Brody and Quigley[4] have examined the balloon–water manometer technique for measuring intra-lumen pressure in the digestive tract and have demonstrated that inflated balloons and water manometers produce a number of artefacts in the pressure records which become unreliable and inaccurate. Such criticisms could be applied with even greater force to recordings made in this way from the very capacious reticulo-rumen where differential contraction and relaxation of the various subsidiary sacs occurs[5]. Brody and Quigley advocate the use of open-ended small-bore tubes connected to electromanometers as the technique of choice for the accurate measurement of pressure within the gut.

This method has been used for measuring the pressure within the reticulum of the goat using a 'Polythene' tube (2·0 mm. int. diam.) passed into the œsophagus intra-nasally. Pressure variations were registered by means of a Hansen capacitance manometer and d.c. amplifier and displayed by means of an Ediswan pen oscillograph. It was easy to make pressure records while the tube was being manipulated within the alimentary tract, so that entry of the tube into the antrum of the reticulum was indicated precisely by the replacement of the rapid respiratory pressure changes with the slow pressure variations of the reticulo-ruminal contraction cycle.

Pressure records made in this way show the well-known contraction of the reticulum occurring regularly at 43–52 sec. intervals, the pressure rising from near atmospheric level to 50 cm. water or more in 2–3 sec. and falling rapidly in 1–2 sec. to the resting level. Pressures up to 65 cm. water have been recorded, but 50 cm. water was the more common value of intra-reticular pressure recorded from eight goats on numerous occasions. Electromanometer pressure records from the antrum of the reticulum do not show the biphasic peak which is a feature of recordings when balloon–water manometer systems are used deep in the reticulum. Smaller and irregular pressure waves of up to 20 cm. water were also recorded from the reticulum near the cardia, and since these pressures accord with those obtained when the tube is pushed farther posteriorly it is likely that they are produced by contraction of the rumen musculature.

The figure of 50 cm. water reported here, although more than double the value recorded from the reticulum by balloon systems inserted through a rumen fistula, can be regarded as authentic, the disparity being due to the physical characteristics of the recording systems. This new result agrees very well with the pressures evoked in the reticulum following electrical stimulation of that region of the medulla oblongata which exerts control of the reticulum and rumen[6]. Pressures of this order have also been recorded by means of electromanometers from the reticulum of cattle during experimental studies of eructation phenomena[7].

It is possible that the rapid development of high pressure within the reticulum close to the cardia plays a part in the forward propulsion of ingesta during the regurgitative phase of rumination. As yet it has not been possible to measure the pressure in the reticular antrum during rumination as the presence of the tube in the œsophagus appears to inhibit the process.

Distribution of Radioiodinated, Acetone-killed *Brucella abortus* in the Tissues of Normal and Immune Mice

THE distribution of radioactively labelled antigens in animal tissues has been studied extensively. Most of the work has been done in normal animals, using simple antigens. Few direct comparisons have been made of the distribution of labelled antigens in normal and immune animals, and no work seems to have been done along these lines with a killed bacterial antigen.

Table 1. RADIOACTIVITY IN SELECTED MOUSE ORGANS (PER CENT OF RADIOACTIVITY INJECTED)

Time after administration of radioactive bacteria \ Immunizing dose (mgm.)	Liver			Spleen			Peritoneal membrane			Mesenteric lymph glands		
	None	0·07	0·5	None	0·07	0·5	None	0·07	0·5	None	0·07	0·5
6 hr.	13·5	12·0	7·2	4·2	1·2	0·5	3·2	4·8	8·0	1·7	3·8	5·0
1 day	12·0	3·2	7·6	4·3	0·7	0·7	1·5	3·0	3·5	1·3	6·2	2·0
3 days	6·2	4·1	2·7	2·5	0·6	0·4	1·0	0·9	1·3	1·6	3·2	3·1
6 days	3·2	0·7	1·5	1·6	0·15	0·2	1·5	1·2	0·4	0·4	2·6	1·1

Acetone-killed *Brucella abortus* 2308 was used in the present study, both as immunizing and as test antigen to be followed in the tissues. Mice were immunized by a single subcutaneous injection of 0·07 or 0·5 mgm. bacteria. Two weeks later they were 'challenged' intra-abdominally with 0·4 mgm. radioiodinated *Brucellae* of the same strain. The iodination was carried out with approximately 80 μc. iodine-131, following the technique of McFarlane[1] slightly modified for the present purpose. The material injected had a specific activity of 300,000 c.p.m./mgm. dry weight bacteria, as measured in a 'Tracerlab' well-type scintillation counter. More than 98 per cent of the activity was bound to the bacteria. Six mice of each group were placed in metabolism cages. Three were killed at 6 hr. and three at 24 hr. after 'challenge'. Other groups of three mice were killed at 3 and 6 days after administration of labelled *Brucellae*. A thorough search was made for the injected radioactivity in the internal organs of the mice. The main findings are summarized in Table 1, which shows striking differences between the normal and the immune groups. While the livers and spleens of the normal animals had a higher radioactivity than the corresponding organs of the immune animals, the reverse was true for the peritoneal membrane and the mesenteric lymph glands. Moreover, in several instances, especially at 6 hr. after injection, a direct relationship could be observed between the radioactivity in the organ and the immunizing dose. Thus, at 6 hr., the stronger the immunizing dose the smaller the radioactivity in the spleen and liver and the larger that in the peritoneal membrane and mesenteric lymph glands. This regularity of response suggests that it might be possible to use the present technique in the assay of the potency of vaccines. The similar behaviour of the spleen in experiments with living *Brucellae*[2] strengthens this assumption.

An interesting finding was the rapid excretion of the radioactivity from the body. 35–40 per cent of the injected iodine-131 was excreted during the first 6 hr. Since the radioactivity found in the urine was apparently attached to low-molecular compounds, as determined by dialysis, precipitation of the activity with silver nitrate and lack of precipitation with *Brucella* antiserum, it must be concluded that the excretion was due to a rapid breakdown of the antigen. High excretion-rates of the label have been found by several other workers[3-5].

It appears, therefore, that the animal can use two completely different mechanisms for the destruction of foreign antigenic material, one acting rapidly during the first few hours after injection, the other acting more slowly, after the antigen has been deposited in the organs, presumably through the intervention of the antibody.

Full details of this work will be published.

I am indebted to Mr. G. Rasooly for technical assistance.

Fibrinolysis Autographs

Permin and Astrup used a plate method of demonstrating fibrinolytic activity[1,2]. This technique can be applied histologically. A thin layer of fibrin is

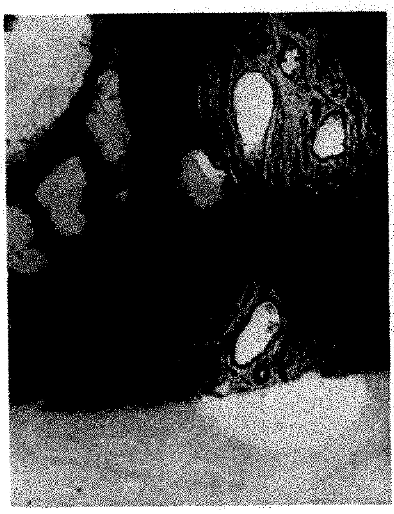

Fig. 1. Section of human prostate showing lysis of fibrin in relation to veins (stained with hæmalum and eosin). × *c.* 47

made on a microslide by adding a drop or two of fibrinogen to a film of thrombin on the glass. When the fibrin layer has formed, a section of fresh or alcohol-fixed tissue cut on the freezing microtome is applied to its surface and the preparation incubated at 37° C. After 30–60 min. patches of digestion of the fibrin appear in relation to structures possessing fibrinolytic activity. These patches appear as clear zones when the preparations are stained with hæmalum and eosin (Fig. 1), and can be related to the structures in the section.

Of the human tissues so far examined (including thyroid, lung, uterus, ovary, prostate, adrenal, kidney, liver, heart muscle and spleen), all, with the exception of liver, show scattered foci of fibrinolytic activity. These are consistently related to veins or venous sinusoids and, to a lesser extent, arteries, except in the lung, when they are predominantly related to pulmonary arteries.

Prolongation of the Life of *Drosophila subobscura* by a Brief Exposure of Adults to a High Temperature

THE life-span of *Drosophila subobscura* at 20° C. (the temperature at which this species is normally kept in the laboratory) can be increased by exposing adults to a high temperature soon after their emergence from the pupa. But first the results of keeping adults continuously at the same temperature will be described.

It has long been known that the life-span of *Drosophila*, and of poikilotherms generally, decreases with increasing temperature[1,2]. For the F_1 hybrids between the *K* and *NFS* inbred lines of *D. subobscura* the results obtained, for flies kept as mated pairs, and transferred to fresh food at regular intervals, are given in Table 1.

Table 1

Temperature (° C.)	Mean adult life-span (days) Males	Females
20	67·4	55·9
25	27·0	35·5
30·5	7·6	17·6

At temperatures above 31° C. the expectation of life falls very rapidly to less than 24 hr. at 33° C. There are reasons for thinking that the changes which occur in individuals at temperatures above 31° C. are different in kind from those occurring below 31° C. Thus if flies are exposed to 33° C. for 8-hr. periods, with intervening periods of 16 hr. at 20° C., their total survival-time at 33° C. is much greater than that of flies kept continuously at 33° C. In this sense the changes occurring at 33° C. are 'reversible', as are the changes which occur at still higher temperatures[3]. In contrast, changes occurring at 30·5° C. are irreversible, in that the total survival-time at this temperature is not increased by an intervening period of 8 days at 20° C.

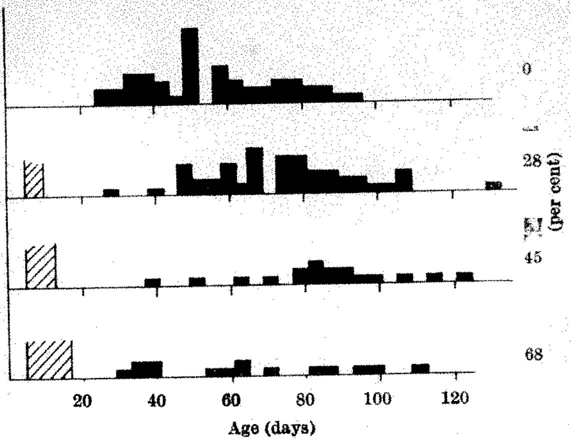

Fig. 1. Ages at death of female *D. subobscura* kept at 20° C., but exposed soon after emergence to 30·5° C. for 0 per cent, 28 per cent, 45 per cent and 68 per cent of their expectation of life at that temperature. Periods spent at 30·5° C. are indicated by hatching

Turning to the evidence for a prolongation of life by exposure to high temperatures, Fig. 1 shows the results of exposing adult females soon after emergence to 30·5° C. for 5–12 days (that is, 28–68 per cent of their expectation of life at that temperature) and then returning them to 20° C. Females so exposed lived for up to 50 per cent longer than did females kept continuously at 20° C.

Two conclusions follow. First, the life-span at 20° C. can be increased by exposing adults to 30·5° C. soon after emergence. It seems likely that one effect of this exposure is permanently to reduce the rates of metabolic processes at 20° C. This is suggested by the fact that the rate of egg-laying is much higher in females kept continuously at 20° C. than in females previously exposed for 5 days to 30·5° C.

The second conclusion is that at least two separate processes of senescence can occur in *Drosophila*. By senescence is here meant those changes occurring in an individual which render that individual more likely to die as it gets older; in other words, senescence is measured by the increase in the force of mortality with age. Now there are some environments in which the force of mortality increases with time, but in which the causes of death have little to do with senescence; for example, animals kept without food would in time die, but this would not be regarded as senescence because it is known that if, after a shorter period of starvation, the animals had been fed, they would have recovered completely. For the same kind of reason the reversible changes in flies kept at 33° C. are not regarded as senescence. But it does seem reasonable to regard as senescence the changes which ultimately kill flies kept continuously at 30·5° C., since they are not reversed in individuals returned for a time to 20° C. Now these senescent changes occurring at 30·5° C. (which may or may not be the same as the changes, also occurring at 30·5° C., which increase the subsequent life-span at 20° C.) cannot be the same as the senescent changes at 20° C., since if they were the same they would be expected to reduce rather than to increase the expectation of life at the latter temperature.

It follows that different processes of senescence occur at 20° C. and at 30·5° C. If so, it does not augur well for attempts to find a single fundamental cause of ageing in this species ; by analogy, there may well be a number of different and partly independent processes of ageing in mammalian species, although in a homiotherm these processes would not be so easily separable.

A full account of this work is in preparation. The investigation was assisted by a grant from the Nuffield Foundation.

Growth and Titration of Louping-ill Virus in Monolayer Tissue Culture of Pig Kidney

Rivers and Ward[1] reported the propagation of louping-ill virus in a Maitland-type culture of chick embryo tissue. More recently, Oker-Blom[2] has described a cytopathogenicity in HeLa cell culture induced by louping-ill which permitted titration of the virus. I have found a specific cytopathogenic effect by the same viral agent in monolayer culture of pig kidney.

The louping-ill virus was a strain isolated and maintained at the Moredun Institute and is used here as infected mouse brain. Virus dilutions were prepared in physiological saline (0·85 per cent sodium chloride) incorporating 10 per cent normal sheep serum, and titrations were carried out intracranially in four 3–5 week old white mice per dilution. Mice were observed for fifteen days following inoculation, and the 50 per cent end-point arrived at by the method of Reed and Muench[3]. The method of culture of pig kidney was that made available by Sellers (personal communication), the trypsin-dispersion of the renal cells having been modified to follow more closely the recommendations of Rappaport[4]. Initial cultures were grown in 'Pyrex' Roux bottles (12 cm. × 20 cm.) by introducing 60 ml. of cell suspension containing 8×10^5 cells per ml. of nutrient medium. The medium comprised Earle's saline, 0·5 per cent lactalbumen hydrolysate (enzymatic) and 0·01 per cent yeast extract ; to this mixture was added 10 per cent normal cattle serum as well as antibiotics. By this method almost confluent monolayers were formed by the sixth day of incubation at 35° C. At this time the cells were subcultured into 'Pyrex' tubes (1·6 cm. × 15·0 cm.) containing cover-glasses (0·63 cm. × 2·22 cm.) by introducing into each 0·5 ml. of cell suspension containing 8×10^5 cells per ml. of medium. Cultures were ready for inoculation by the second or third day of incubation, when continuous monolayers were formed. Further incubation was carried out in roller drums.

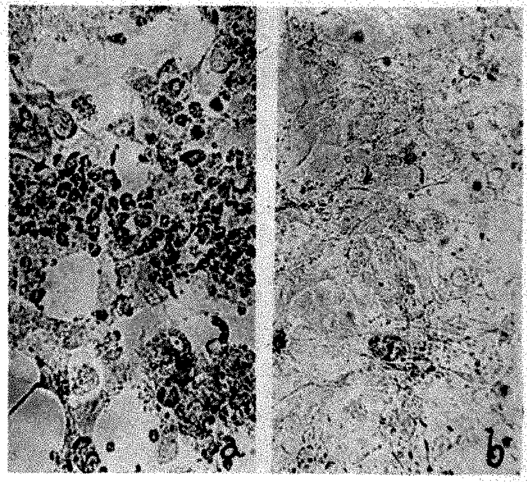

Fig. 1. (*a*) Cytopathogenicity produced in pig kidney monolayer tissue culture by approximately 300 *CPD*50 doses of louping-ill mouse brain virus in the presence of an equal volume of normal sheep serum diluted 1 in 100. (*b*) Normal pig kidney monolayer 'protected' from the same amount of virus by an equal volume of louping-ill hyperimmune sheep serum diluted 1 in 100. The source and age of the cells as well as the period of incubation with virus were identical with (*a*). × 110

Virus was passaged serially in culture by transferring pooled undiluted or diluted infected medium from one group of four to six tube-cultures to each of a group of newly prepared ones. Passage virus was harvested on the sixth day of incubation and titrated immediately in mice. By the fifth passage the original virus inoculum titre of 4×10^4 mouse *LD*50 doses per ml. was diluted 10^7 but yielded $3{\cdot}9 \times 10^7$ mouse *LD*50 doses per ml. Clearly, the cultures were supporting multiplication of the virus. Microscopic examination of live cultures inoculated with low dilutions of mouse brain virus revealed a cytopathogenic effect which commenced on the second to third day. The affected cells became granular, rounded up, and appeared to agglutinate (Fig. 1). As the effect increased in severity, there was almost total cell necrosis and destruction of the monolayers. Fixed coverslip preparations of affected cells stained with Giemsa showed shrinking, pyknosis and disintegration. Uninfected cultures and cultures inoculated with comparable dilutions of normal mouse brain remained unchanged.

Titration of virus in culture on the basis of the presence or absence of cytopathogenicity was carried

Table 1. NEUTRALIZATION OF THE CYTOPATHOGENICITY INDUCED BY LOUPING-ILL MOUSE BRAIN VIRUS IN PIG KIDNEY MONOLAYER TISSUE CULTURE BY SPECIFIC HYPERIMMUNE SHEEP SERUM. SIMULTANEOUS NEUTRALIZATION IN MICE INOCULATED INTRACRANIALLY IS ALSO SHOWN

Test system	Inoculum (ml.)	Quantity of virus	Sheep serum log dilution											
			Normal						Louping-ill hyperimmune					
			Undil.	10^{-1}	10^{-2}	10^{-3}	10^{-4}	10^{-5}	Undil.	10^{-1}	10^{-2}	10^{-3}	10^{-4}	10^{-5}
Culture	0·1	300 *CPD*50	5/5*	5/5	5/5	5/5	5/5	5/5	0/5	0/5	0/5	0/5	5/5	5/5
Mice	0·05	300 *LD*50	4/4†	3/3	4/4	4/4	4/4	4/4	0/4	1/3	0/4	1/3	4/4	4/4

* Numerator: No. of tube-cultures showing cytopathogenic effect up to the sixth day after inoculation of serum–virus mixture. Denominator: No. of tube-cultures inoculated with serum–virus mixture.

† Numerator: No. of mice killed showing typical symptoms of louping-ill up to the fifteenth day after inoculation of serum–virus mixture. Denominator: No. of mice inoculated with serum–virus mixture.

out by adding tenfold dilutions of mouse brain virus to groups of five tube-cultures. Results were read on the sixth day of incubation under low-power magnification and the 50 per cent end-point calculated as in mice. Mice were inoculated simultaneously with the identical virus dilutions. One cytopathogenic (50 per cent) dose (*CPD*50) was determined to be equivalent to 400–600 mouse *LD*50 doses.

Neutralization of the cytopathogenic effect in culture was carried out both by serum and virus dilution techniques. The results of a test in which tenfold dilutions of sera were tested against approximately 300 *CPD*50 doses and 300 mouse *LD*50 doses of mouse brain virus in cultures and mice respectively are shown in Table 1. Serum–virus mixtures were incubated for 2 hr. at room temperature (22° C.) followed by $\frac{1}{2}$–1 hr. at 4° C. prior to inoculation into the test systems; results were read as before. The marked inhibition of cytopathogenicity by louping-ill hyperimmune sheep serum was regarded as proof of the specificity of the reaction.

Treatment of Hops with Dimefox

DIMEFOX, a systemic insecticide, is extensively used in commercial practice for the control of the hop aphis (*Phorodon humuli*) and the hop red spider (*Tetranychus urticae*). Because of toxic hazards it is not used as a spray or dust but is applied via the soil at the rate of approximately 0·5 gm. active ingredient in 120 ml. water per plant or hill. A single application is normally made each season in May or June.

The plants involved in this investigation were grown at Wye at a spacing of 6 ft. 6 in. (2 m.) square on wirework 14 ft. 6 in. (4·4 m.) high. Dimefox was applied to all plants at 0·5 gm. per hill on May 31; a second application at 0·25 gm. per hill was made to some of the plants on July 19. Samples of leaves were collected at different heights at intervals throughout the season up to the time of harvesting, and were analysed in the Department of the Government Chemist. Samples of ripening cones and dried hops were also examined.

It was found that the progress of the insecticide from the soil to the plant could be followed by means of the analytical figures. The rate of travel in the plant itself could be measured by examining leaves from different levels.

The method of analysis used throughout this work was that of Field and Laws[1]. The samples, when picked, were packed in air-tight 'Polythene' bags and were examined immediately on arrival at the laboratory. The results are expressed as p.p.m. on the samples as received, no attempt being made to correct for moisture content.

Table 1. DIMEFOX CONTENT OF LEAF SAMPLES FROM TREATED HOP PLANTS

Days from treatment	Height of leaves above ground-level		P.p.m. dimefox	
	Bottom sample	Top sample	Bottom sample	Top sample
Control	2 ft.	—	0·1	—
4	3 ft.	—	3·5	—
11	3 ft.	7 ft.	2·2	1·2
18	3 ft.	8 ft.–8 ft. 6 in.	2·5	3·2
32	4 ft. 6 in.	11 ft.	1·6	0·9
39	4 ft. 6 in.	11 ft.	1·9	1·0
47	4 ft. 6 in.	12 ft. 6 in.	0·9	1·0
53 (3)	4 ft. 6 in.	12 ft.	0·8 (2·9)	0·6 (2·0)
58 (8)	4 ft. 6 in.	12 ft.	1·0 (1·4)	1·1 (6·0)
72 (22)	4 ft. 6 in.	12 ft.	0·1 (0·2)	0·3 (0·4)

Treatments: 0·5 gm. dimefox per hill on May 31, 1937, to all plants; a further 0·25 gm. dimefox per hill on July 19, 1957, to some plants. Data for plants given a second treatment in brackets. 50-gm. sample examined in each case

The results of the leaf analyses are given in Table 1. In each case a representative 50-gm. sample was examined. When dried cones were examined, only 10 gm. was taken.

The figures show that dimefox is rapidly taken up and transmitted to the whole plant until a steady state is reached lasting for several weeks. Increase in the amount of dimefox in the soil brought about by the second application on July 19 showed up about a week later in the upper part of the plant.

Analysis of the ripening cones showed that in the plants which had received only the single application on May 31, 94 days before sampling, the level of dimefox concentration was 0·1 p.p.m. In those plants which had also received the second application on July 19, 44 days before sampling, the level was 0·3 p.p.m.

Harvesting took place in September, 108 and 60 days respectively after the first and second applications. Analysis of samples dried in the commercial manner to about 10 per cent water content showed the level of dimefox to be 0·13 p.p.m. in hop cones from plants which had received the first application only. In the dried cones from plants that received both applications, the concentration of dimefox was 0·33 p.p.m. These values correspond to 0·03 p.p.m. and 0·07 p.p.m. respectively in terms of fresh green material. Such residues would appear to be too low to constitute a health risk.

The results demonstrate the uptake and distribution of dimefox in hops. Many more experiments under different conditions will be necessary before the behaviour of this insecticide is fully understood. It is not at present known whether the dimefox undergoes chemical break-down in the plant or whether it evaporates with the moisture from the leaves. These investigations show that it does not remain as dimefox in the plant tissue.

Reduction of Parathion induced by Light

While investigating the decomposition of parathion (O,O-diethyl-O-*p*-nitrophenylphosphorothionate) I was able to confirm the findings of Ketelaar[1] on the specific action of Cu^{2+}-ions in catalysing the hydrolysis leading to *p*-nitrophenol. Other metal ions are ineffective, and the catalytic action of copper can be suppressed by various chelating agents[2]. The experiments were carried out at room temperature in a barbiturate milieu at *p*H 8·0 and lasted for more than four weeks. Change in concentration of parathion with a modified polarographic method was followed, and this permitted the estimation of parathion and simultaneously of the *p*-nitrophenol formed. In certain instances however, in solutions not containing the catalyst, a significant decrease of the polarographic wave of parathion was observed though the corresponding appearance of *p*-nitrophenol was not detected. Although in publications dealing with the degradation of parathion[4] there is no allusion to the possibility of a spontaneous reduction, I have shown it to be induced by light.

A 2×10^{-3} *M* solution of parathion (prepared from 20 per cent parathion 'Paridol', Chemisch-Technische Werke A.G. Muttenz-Basel—a material not containing appreciable amounts of degradation products) in 5×10^{-2} *M* *p*H 8·0 barbiturate buffer was divided into several portions and some of them were exposed to direct sunlight. The irradiation was carried out in thin-walled Jena test-tubes. The temperature was controlled continuously and the portions kept in the dark were thermostated according to the temperature of the irradiated specimens. At intervals, samples were taken and analysed by: (*a*) polarography, which gives the amount of non-degraded parathion and any *p*-nitrophenol present; (*b*) the method of Averell–Norris[5], which gives estimates of the intact and reduced parathion; (*c*) the method of Averell–Norris, which was modified for this purpose, omitting the reduction step, thus giving values of the reduced parathion only.

Table 1. Degradation of Parathion Solutions kept in the Dark and exposed to Sunlight

Solution tested	Age of solution	Polarographically		Averell–Norris	
		Parathion	*p*-Nitrophenol	Reduced parathion	Parathion +reduced parathion
		Molarity × 10^4			
'Paridol' alone	2½ hr.				
Dark		20	traces	nil	19
Light		16	traces	5	21
Dark	5½ hr.	20	traces	nil	20
Light		14	traces	7	20
'Paridol'+ copper	2½ hr.				
Dark		13·5	6	nil	14
Light		11	7	1·5	14
Dark	5½ hr.	6·5	12·5	nil	7·5
Light		3	13·5	1·9	6
'Paridol'+ copper+ EDTA	2½ hr.				
Dark		20	traces	nil	23
Light		16	traces	5	21
Dark	5½ hr.	20	traces	nil	24
Light		14	traces	8	22

The solutions contained 0·002 *M* parathion in a 0·05 *M*, *p*H 8·0 barbiturate buffer. Copper ions were applied at a 10^{-4} mol. and ethylenediamine tetraacetate at a 10^{-3} mol. concentration. The results are representative ones, and were obtained on a hot July day in 1957 in Budapest, the temperature of the solutions being 35–45° C.

In parallel experiments I investigated the effect of Cu^{2+}-ions alone and in presence of ethylenediamine tetraacetate. The copper ions, as expected, catalysed the hydrolytic degradation of parathion to *p*-nitrophenol, competing with the light-induced reduction. The chelating agent inhibited the catalytic action.

The results, of which a representative series is given in Table 1, clearly show the photochemical reduction of parathion, presumably to the corresponding *p*-amino-compound. Similar results were obtained by irradiation with a mercury discharge lamp. It is planned to conduct further experiments in order to investigate the effect of *p*H, various other metals and chelating agents, and the behaviour of spray residues under field conditions.

Gibberellin and the Growth of Plant Tissue Cultures

Two recent publications report the effects of gibberellic acid on the growth of excised plant tissues. Netien[1], working with isolates from the tuber parenchyma of *Helianthus tuberosus*, found a slight increase in growth at 1 p.p.m. in the absence of indolylacetic acid and a decrease at higher levels. In the presence of the auxin all levels of gibberellic acid were quite inhibitory. Schroeder and Spector[2] used explants from the mesocarp of mature citron (*Citrus medica*). They found gibberellic acid, in the absence of indolylacetic acid, caused an increase in weight at 5 p.p.m. In the presence of indolylacetic acid all levels tested resulted in increases in weight.

This report is concerned with the effect of gibberellins on the growth of plant tissues *in vitro* using well-established, actively proliferating clones. The present results are part of a larger report now being prepared. The tissues discussed here were selected to show that an increase in growth, no effect, or a decrease in growth can be obtained under the same conditions by changing the test material.

All the tissues listed in Table 1 have been in culture in this laboratory for the past seven years. The basal synthetic medium used for all tissues consists simply of mineral salts, sucrose, three vitamins, trace elements, and agar[3]. Gibberellin stock solutions were made up at ten times the desired concentration, sterile-filtered through sintered glass, and added to give the desired level to previously autoclaved basal medium just prior to solidification. Experimental transfers of equal size were made to the solid medium and initial weights recorded. After four and eight weeks growth in an air-conditioned culture room at 22·5° C., the tissues were weighed. The results are expressed in Table 1 as 'growth value', which is a number obtained by dividing the final wet weight by the original wet weight. All values are the average of two experiments with five replicates in each experiment.

Table 1. Effect of Gibberellin on Growth of Plant Tissue Cultures on Synthetic Medium

Plant source	Part	Type of tissue	Growth value			
			4 weeks		8 weeks	
			Control	Gibberellin (10 p.p.m.)	Control	Gibberellin (10 p.p.m.)
Helianthus annuus	Petiole	Crown gall	12·8	4·4	49·1	11·0
Vinca rosea	Stem	Crown gall	6·3	2·0	35·4	4·3
Nicotiana tabacum	Stem	Crown gall	3·4	3·8	13·5	15·8
Melilotus officinalis	Stem	Crown gall	2·6	2·9	8·9	14·3
Melilotus officinalis	Root	Callus	2·2	3·1	7·0	15·8

These results are only indicative of the results using 10 p.p.m. of gibberellin. Even at this one level, however, it is apparent that no generalizations can be made concerning the effects on plant tissues *in vitro* since both stimulation and inhibition result according to the test material.

A broader account is now being prepared which takes into consideration such problems as the effects of different levels of the gibberellins, the effects of varying the medium and the importance of the type of tissue used as well as its source.

Effect of Gibberellic Acid on the Growth of Pea Seedlings when imbibed through the Seed Coat

Stowe and Yamaki[1], in a recent review paper, have listed two hundred and two references relating to the isolation and effects of the gibberellins upon various physiological processes in plants.

Work with these plant-growth substances has, however, been primarily concerned with their effects upon plant growth and development subsequent to germination. It is the purpose of this brief communication to demonstrate that gibberellic acid may produce a typical response when imbibed through the seed coat of the dwarf Telephone pea prior to germination.

Approximately fifty dwarf Telephone pea seeds were planted in each of two small wooden flats filled with sterile vermiculite. The flats were placed over porcelainized germination pans so that added solutions could be retrieved after dripping through the vermiculite. Directly after planting, the vermiculite in one flat was saturated with a solution of 1·0 mgm./l. gibberellic acid. The second flat was supplied with distilled water. The solutions caught in the germination pans were poured back over the respective flats daily until utilized or lost. Plants were grown in the greenhouse under long-day (16 hr.) conditions.

Eleven days after planting, treated and control seeds had germinated and were well above the level of the vermiculite. Treated dwarf pea seedlings were, at this time, approximately six times as tall as the control seedlings. The percentage of germination in both flats was comparable.

Seventeen days after treatment the plants in both flats were harvested. The heights of treated seedlings were significantly greater than the heights of control seedlings. The axillary buds, as well as the main axes of the stems, exhibited markedly increased elongation in treated plants. The stems of the treated seedlings were markedly thin as compared with the controls.

Subsequent experiments have revealed that the response to gibberellic acid described above may also be obtained by allowing dwarf pea seeds to imbibe gibberellic acid solution prior to planting.

Genetic Effects of Carbon Monoxide, Cyanide and Azide on *Drosophila*

The study of chemical mutagenesis has directed attention to the possibility that the so-called spontaneous gene mutations may in fact result from the accumulation of mutagenic substances arising as a consequence of normal metabolism. In bacteria, the spontaneous mutation-rate of dividing cells may be 40 times greater than that of non-dividing cells[1]. On the other hand, there does not seem to be any simple relation between mutation and cell division itself[2]. This may be interpreted to mean that, as a result of metabolic activity associated with synthesis and growth, chemical mutagens arise and may eventually react with the genetic material. The discovery of 'anti-mutagens'[3] would appear to support this hypothesis. An anti-mutagen might directly mop up traces of the mutagen, or it might initiate further biochemical reactions serving to divert the mutagen into alternative channels.

D'Amato and Hoffman-Ostenhof[4] have recently reviewed the possibility that spontaneous mutation in plants may result from the accumulation of mutagenic by-products of metabolism. The genetic effects of respiratory inhibitors are clearly relevant to the problem. Although some inhibitors might prove to be mutagens in their own right, capable of reacting more or less directly with the genetic material, others might operate simply by disturbing normal metabolic activity in such a manner that an excessive production of natural mutagens results, enabling a greater number of 'spontaneous' mutations to be recorded. Cytogenetic analysis of such mutations would give a picture essentially the same as that obtained from the analysis of spontaneous mutations obtained from untreated material. We should also keep in mind the possibility that any genetic effects of respiratory inhibitors might stem from interference with recovery processes. Wolf and Luippold[5] have found an association between oxidative metabolism and the restitution of radiation-induced breaks in root tip cells of *Vicia*.

Conger and Fairchild[6] reported some years ago that even the simple metabolic experiment of increasing oxygen tension can induce chromosome breaks in *Tradescantia*, suggesting that the oxygen normally present in the air may be responsible for the low spontaneous frequency of aberrations. If the normal rate of oxygen metabolism is exceeded, more genetic damage results.

Inhibitors known to block heavy-metal respiratory enzyme systems have been shown in some cases either to be mutagenic or to be capable of modifying the effectiveness of irradiation treatments[7–13]. In *Drosophila*, injection of cyanide or azide solutions into adult males does not prove to be mutagenic[14]. Nor is carbon monoxide mutagenic when used alone. However, it seemed possible that combined treatment with two inhibitors might prove effective where single treatments had given negative results.

Genetic effects were scored as sex-linked recessive lethals obtained by the usual Muller-5 technique, using Canton *S* males as test material. The incidence of such lethals in untreated males of this stock is about 0·1 per cent for sperm produced within the first few days.

Successive broods were obtained by transferring each male to three fresh females every third day. Both the azide and cyanide were used as 0·005 *M* solutions in 0·7 per cent sodium chloride. In the case of the cyanide, the *p*H was adjusted to 7·0 just prior to injection. The carbon monoxide treatment consisted of exposure of the flies immediately after injection to a gas mixture of 95 per cent carbon monoxide with 5 per cent oxygen at 18° C. for 6 hr. Carbon monoxide alone is not mutagenic under the conditions of testing. However, when supplemented by simultaneous treatment with either cyanide or azide, a mutagenic effect is obtained (Table 1). On the other hand, in the absence of carbon monoxide, cyanide and azide are themselves not mutagenic[14], although together they may elicit a weak response (Table 1).

Table 1. SEX-LINKED RECESSIVE LETHALS OBTAINED FROM CANTON *S* MALES

Brood	Carbon monoxide	Azide–carbon monoxide	Potassium cyanide–carbon monoxide	Azide–potassium cyanide
	(per cent)	(per cent)	(per cent)	(per cent)
1	1/545 (0·18)	6/436 (1·38)	3/319 (0·94)	0/374
2	1/496 (0·20)	4/573 (0·70)	2/377 (0·53)	2/449 (0·44)
3	0/407	3/355 (0·84)	1/281 (0·35)	1/412 (0·24)
4	0/284	1/419 (0·24)	1/312 (0·32)	1/390 (0·26)
5	0/178	0/242	0/195	0/211

Combined treatment with carbon monoxide and either cyanide or azide is also mutagenic to spermatozoa stored within the spermathecæ of inseminated females, although in this case the yield of offspring is small owing to the small number of eggs laid by *Drosophila* females after exposure to the gas.

Theories of peroxide formation have been prominent in much of the current work on chemical mutagenesis and a peroxide theory might appear to provide the simplest explanation for the effectiveness of carbon monoxide when supplemented by azide injections. The first inhibitor, by blocking the cytochrome pathway, would direct activity into a flavoprotein respiratory pathway with peroxide as a terminal product. The second inhibitor, by blocking the activity of catalase, would facilitate the accumulation of the peroxide beyond the threshold concentration. However, this simple explanation ignores the fact that cyanide and azide alone are not mutagenic in *Drosophila*, although they are inhibitors of both cytochrome oxidase and catalase. In the case of cyanide, it is possible that the inhibition of catalase is only transitory, for the accumulation of peroxide might well serve to oxidize the cyanide to cyanate and thus relieve the inhibition of the enzyme. On the other hand, cyanide is not to be regarded as a cytochrome oxidase inhibitor with the same degree of specificity as carbon monoxide. Nor for that matter is azide. No doubt both these inhibitors have other important biochemical effects. There is evidence that even carbon monoxide itself may, under certain conditions, serve to stimulate respiration[15], and the mutagenic effectiveness of combined treatments with this inhibitor might find an explanation along these lines.

Hydrogen sulphide is also capable of blocking the activity of both cytochrome oxidase and catalase, but it does not seem to be mutagenic in *Drosophila*. We have found that exposure of males or inseminated females to 1 : 1,000 hydrogen sulphide for 15 min. (approximately *LD*50) fails to increase mutation-rate. Combined treatments with cyanide or azide give weak responses which, however, are not statistically significant. The effect of simultaneous treatment with carbon monoxide and hydrogen sulphide has not been tried.

As hydrogen sulphide is extremely toxic to *Drosophila*, it may not be possible to administer a dose that is mutagenically effective without at the same time achieving a killing action on the cells. Certainly, flies which have been treated with this gas show very poor fertility.

The different mutagenic responses obtained from these various treatments emphasize the complexity of the biochemical mechanisms involved. Interpretation in terms of the simultaneous inhibition of heavy-metal respiratory enzymes is undoubtedly an over-simplification. It is hoped that further work along these lines will be directed towards a cytogenetic analysis, enabling a qualitative comparison to be made between spontaneous mutations recovered from untreated material and those recovered from material receiving combined azide–carbon monoxide treatment.

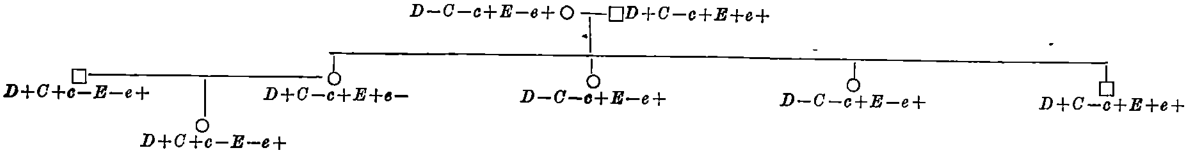
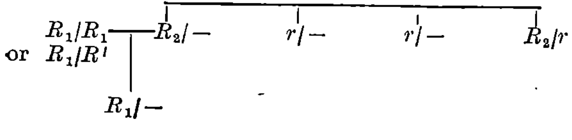
A New 'Deleted' *Rh*-Chromosome

In 1950, Race, Sanger and Selwyn reported[1] a very unusual *Rh* phenotype characterized by an extraordinary strong reaction with anti-D sera and completely negative reaction with anti-C, anti-c, anti-E and anti-e sera. The case was explained as the homozygous form of a partially deleted *Rh* chromosome, designated $D - -$. Since then several examples of this chromosome have been reported, and further other partial deletions have been found[2].

Recently an apparent mother-child exclusion was found in our laboratory. In a legal paternity case the mother was of phenotype $D + C - c + E + e -$, the child of phenotype $D + C + c - E - e +$. The results were checked with a number of different anti-Rh sera both in saline and using papainized cells and the indirect Coombs reaction. The possibility of an error while taking the blood sample was excluded by investigating new samples from the people concerned. The child was born in hospital, but the risk of an interchange of babies in the maternity ward was negligible, as the child was the only premature baby in the ward at that time. However, the ensuing investigation of the family definitely established the kinship of mother and child. The *Rh* types of the family, which were rather surprising, are shown in the following pedigree, + signifying positive and − signifying negative reaction with the corresponding antibodies.



It is seen that there is an apparent exclusion of maternity in the first generation as well as in the second, the *Rh*-negative grandmother having a daughter who appears to be of genotype R_2R_2 or R_2R''. We knew that the irregularity affected the *Cc* as well as the *Ee* loci, but the really unexpected finding was, of course, that the grandmother was *D*-negative. The most simple explanation is a new, partially deleted chromosome involving $d(d - -)$, or a triple deletion ($- - -$). It is of course impossible to ascertain if *d* is present or not, as long as anti-*d* is not available. It is further obvious that one of the criteria on the hitherto known partial *Rh*-deletions, the enhanced agglutinability of the *D*-receptor, cannot be put to use in the diagnosis of $d - -$ or $- - -$. However, it is to be expected that the erythrocytes from persons carrying the abnormal chromosome would show single-dose reactivity with regard to the *Rh* receptors, which according to the phenotype appear to be homozygous. Titration experiments against the pertinent sera appear to substantiate this expectation. According to these experiments the genotypes of the family are the following, − denoting chromosome $d - -$ or $- - -$:



A detailed report on the case and the results will be published later. I wish to thank Dr. A. E. Mourant and Dr. D. Parkin, of the Blood Group Reference Laboratory, Lister Institute, London, who kindly checked the results.

Mitosis and Chromosome Numbers in the Euglenineae (Flagellata)

Nuclear division and the associated division of the cell and cell organelles have been examined in thirty-two species of the Euglenineae, drawn from thirteen genera. The main findings on the structure and mechanics of mitosis in this group are as follows.

Nuclear division in the Euglenineae is a true mitosis in that:

(1) Individualized chromosomes duplicate themselves longitudinally.

(2) Sister chromatids segregate to opposite poles.

The mitosis differs from the 'classical' form in the following ways:

(1) An achromatic body in the nucleus, the 'endosome', persists throughout mitosis, dividing as a structure distinct from the chromosomes (Fig. 1).

(2) The endosome retains its ribonucleic acid during mitosis.

(3) There are no centromeres or spindle.

(4) Mitosis and cell activity are unaffected by 4 per cent colchicine, or by ionizing radiations at doses of up to 100,000 r.

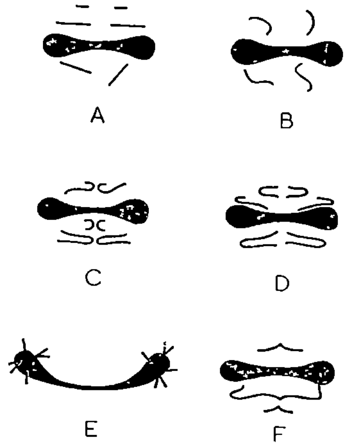

Fig. 1. Chromatid shapes during mitotic anaphase in the Euglenineae. The dividing endosome is also shown

(5) There is no evidence for the presence of centrioles or centrosomes during mitosis. The basal granules of the flagella do not act as division centres.

(6) The chromatin threads become arranged parallel to the division axis at 'metaphase'; in some species the threads are segregating chromatids still associated at one end (Fig. 1, *F*), in others they are chromosomes which become duplicate in their parallel position and segregate in anaphase.

(7) Separation of chromatids is staggered in some species.

(8) There are four main chromatid shapes during anaphase movement: straight rods (Fig. 1, *A*); curving threads (Fig. 1, *B*); U-shapes towards the division equator (Fig. 1, *C*); and U-shapes towards the poles (Fig. 1, *D*). Rods and V-shapes radiating from the ends of the dividing endosome occur in a few species (Fig. 1, *E*).

(9) Anaphase movement of the chromatids is staggered.

(10) The nuclear membrane persists throughout mitosis.

(11) The mitosis lasts 2–4 hr., anaphase occupying 35–86 min. in different species, as compared with 1–20 min. in all other organisms and tissues for which records exist.

(12) The absolute velocity of the chromatids separating at anaphase is less than 0·1μ per min. at 20° C., compared with 0·3–6·0μ per min. for all other recorded material.

In the light of the above evidence, and in the absence of centrioles, centrosomes, true blepharoplasts, centromeres, and spindle, it is suggested that chromatid movement in the Euglenineae is autonomous—a mutual repulsion by sister chromatids to opposite poles. The dense nucleoplasm and the retention of the nuclear membrane during mitosis prevents a scattering of chromatids in the cell. The nuclear membrane is stretched by the two groups of repelling chromatids and separation to two cytologically and genetically equivalent nuclei finally occurs.

A further feature of euglenoid mitosis is the general occurrence of high chromosome numbers. Chromosome counts have rarely been attempted in the Euglenineae. Pringsheim[1] says, "The number of chromosomes has not been established in any case, owing no doubt to difficulty caused by their number, length and dense accumulation. This is to be regretted, because polyploidy may be expected in certain groups".

I have made counts for six species, and estimates for a further eight (Table 1). In most species the clearest counts are obtained in anaphase or telophase.

Table 1. CHROMOSOME NUMBERS IN THE EUGLENINEAE

Counts		Estimates	
Euglena spirogyra	86	*Astasia klebsii*	18
Euglena viridis	42	*Colacium mucronatum*	35
Eutreptia lanowii	90	*Euglena gracilis*	45
Eutreptia viridis	44	*Lepocinclis ovum* var. *buetschlii*	34
Hyalophacus ocellatus	92	*Menoidium cultellus*	15
Phacus pusillus	42	*Peranema trichophorum*	177
		Trachelomonas bulla	25
		Trachelomonas grandis	40–60

The only direct comparisons with records by previous workers are my estimate of 45 for *Euglena gracilis* and a count of 14 by Baker[2], and my estimate of 177 for *Peranema trichophorum* and counts of 6 (!) by Hartmann and Chagas[3] and 32 by Brown[4]. The low counts by these authors were probably caused by fusion of the separate elements in poorly fixed material. The counts of 44 for *Eutreptia viridis* and 90 for *Eutreptia lanowii* indicate possibly polyploidy in this genus.

A full account of this work will be published elsewhere. The study was carried out in the Department of Botany, Queen Mary College, London, and will be continued at the Durham Colleges in the University of Durham. I would like to acknowledge the help and advice of Dr. M. B. E. Godward of Queen Mary College, and of Prof. E. G. Pringsheim of the University of Göttingen.

Number of Mating Types required for Balance in Multipoint Linkage Programmes

IN two-point linkage work it is advantageous to use coupling and repulsion back-crosses in approximately equal numbers, for, with equal numbers of progeny, disturbances due to differential viability need not affect the estimation of the recombination fraction between the two loci. In fact, it is only possible to allow for differential viability in all the segregating phenotypes by this method of 'balance', and it may be shown that the estimation of the recombination fraction is most efficient when the balance is exact. The minimum requirement for balance is that the numbers of progeny from the coupling and repulsion back-crosses must be equal; in other contexts the definition of balance may be narrower, but it is used here as defined by this minimum requirement. This idea is just as fruitful in multi-point linkage work, but it is not necessary to make up matings using all the possible genotypes of multiple heterozygotes in order to ensure a set balanced for all pairs of loci. The present problem is to determine the minimum number of mating types needed for making up a balanced set for any given number of loci.

With two loci we may represent the heterozygote in coupling by $+ +$, and the heterozygote in repulsion by $+ -$. The symbols indicate that in the coupling heterozygote both wild-type genes are on the same chromosome, while in the repulsion heterozygote they are on different chromosomes. The existence of either coupling or repulsion may be inferred from these symbols by multiplying them together. Thus $+ \times + = +$ (coupling), and $+ \times - = -$ (repulsion). The set is said to be balanced when there are equal numbers of coupling and repulsion mating types; that is, when there are equal numbers of $+$ and $-$ signs resulting from this multiplication procedure. If, instead of just $+$ and $-$, we use $+1$ and -1, then the set will be balanced when the sum of the products of the two numbers representing each mating type is zero.

This procedure may be simplified for more than two loci by using a matrix notation. In the example above, we write the symbols for the two mating types one under the other:

$$\begin{matrix} 1 & 1 \\ 1 & -1 \end{matrix}$$

Calling this the matrix a, and its transpose (which is in this case its identity) a^*, the condition for balance is:

$$a^*.a = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} = 2I$$

This is just a convenient way of recording the fact that 'the numbers in any two columns, taken in pairs and multiplied together, sum to zero'. In this example there are only two columns, that is, one pair, but with four loci there are four columns, and so six pairs, one for each pair of loci.

The full solution of the problem is equivalent to the solution of the matrix equation $a^*.a = qI$, where a has p columns and q rows, p being the number of loci, and q the number of mating types in the balanced set.

Mr. S. Wylie, of Trinity Hall, Cambridge, who introduced the matrix notation to this problem, has pointed out that the enumeration of these matrices is equivalent to the enumeration of anallagmatic pavements. An anallagmatic pavement is a square pavement of black and white tiles so arranged that when any two columns or any two rows are placed together side by side, half the tiles next to one another are of the same colour and half are of different colours.

We are only concerned with square matrices, for it is clear that if a set is balanced for p loci, it is also balanced for $p - 1$ loci, and it may be proved, by *reductio ad absurdum*, that there does not exist a balanced set of p mating types for $p + 1$ loci.

A $p \times p$ pavement does not exist for $p > 2$ unless p is a multiple of 4, and it is conjectured[1] that it does exist when p is a multiple of 4. The first doubtful case is $p = 92$, and this is far beyond the range of genetic interest. It is known that pavements exist whenever p is divisible by 4 and of the form $2^k(s^n + 1)$, where s is an odd prime, and k and n are integers. 92 is the lowest multiple of 4 which is not of this form.

Thus we are able to draw up a table of number of loci and the corresponding minimum number of mating types in a balanced set:

Loci	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	
Mating types	2	4	4	8	8	8	8	12	12	12	12	16	16	16	16,	etc.

The enumeration of these pavements for $p > 4$ presents a formidable problem. Two 'basic' pavements are set out below for 8 loci, and many more may be derived from each by the interchange of columns, etc.

$$\begin{array}{cccccccc}
+ & + & + & + & + & + & + & + \\
- & + & - & + & - & + & - & + \\
- & - & + & + & - & - & + & + \\
+ & - & - & + & + & - & - & + \\
- & - & - & - & + & + & + & + \\
+ & - & + & - & - & + & - & + \\
+ & + & - & - & - & - & + & + \\
- & + & + & - & + & - & - & +
\end{array}
\qquad\qquad
\begin{array}{cccccccc}
+ & + & + & + & + & + & + & + \\
+ & - & - & - & + & - & + & + \\
+ & + & - & - & - & + & - & + \\
- & + & + & - & - & - & + & + \\
+ & - & + & + & - & - & - & + \\
- & + & - & + & + & - & - & + \\
- & - & + & - & + & + & - & + \\
- & - & - & + & - & + & + & +
\end{array}$$

Chromosome Breakage in *Vicia faba* by Ozone

Important to an understanding of the biological effects of high-energy radiations is the concept of active radical formation in water[1]. The inability of hydrogen peroxide *per se* to simulate irradiation effects at concentrations expected in the cytoplasm of irradiated cells[2] has focused attention on the active radicals OH and HO_2. The chemical activity of such free radicals produced by the catalytic decomposition of hydrogen peroxide with ferric ions has recently been discussed[3], and Phillips[4] describes the production of chromosome aberrations in barley by these hydrogen peroxide 'precursors'.

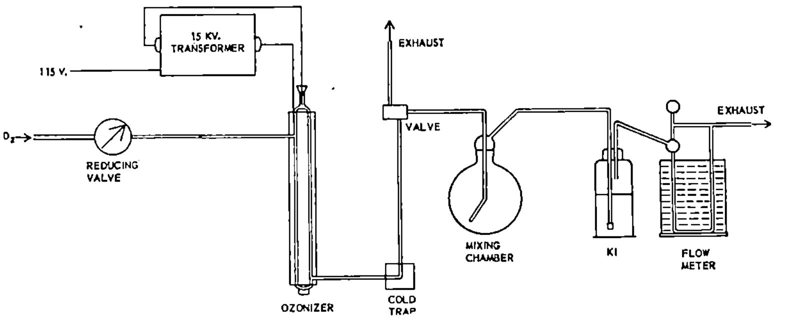

Fig. 1

The decomposition of ozone in solution produces these same active radicals of interest[5]. From studies of the kinetics and mechanisms of ozone decomposition, Alder and Hill[6] assume that in solution the reactions:

$$HO_3^+ + OH^- \rightleftarrows 2HO_2 \qquad (1)$$

$$O_3 + HO_2 \longrightarrow OH + 2O_2 \qquad (2)$$

are responsible for disappearance of ozone and are relatively slow and determine the rate of reaction; also, these authors indicate that reaction (1) represents an equilibrium which is maintained so long as ozone is present. The decomposition of ozone in solution is catalysed by hydroxyl ions and dependent upon temperature[7].

In these investigations, root meristem cells of *Vicia faba* were exposed to an atmosphere of ozone and the fraction of cells showing chromosome aberrations (as anaphase bridges) were recorded. The cells were all exposed in interphase and analysed at the first anaphase.

Fig. 1 is a schematic diagram of the apparatus used for challenging the seeds. The ozone was produced from cylinder oxygen and the concentration calculated by scrubbing replicate samples of known volume through 2 per cent potassium iodide (pH 9·0), the solution acidified and then titrated with 0·1 *N* sodium thiosulphate. With a flow of 2 l./min., 0·4 weight per cent ozone was present. The cold trap was found to be unnecessary and was abandoned. Seed coats were removed from imbibed *Vicia* seeds which were challenged with the ozone–oxygen mixture in the mixing chamber. Batches of seeds were removed after specific intervals, placed in sterile moistened vermiculite, at 19° C. and in the dark, until the radicles were about 2 cm. in length. At this time the first cell divisions occur[8], and Feulgen-stained squash preparations were made.

Table 1 presents the results of exposing *Vicia faba* seeds to 0·4 weight per cent ozone for 15, 30 and 60 min. The term 'abnormal anaphase' is used because no attempt was made to count the number of chromosome bridges per cell; thus an abnormal anaphase may contain one or more bridges. All the bridges observed were of the chromosome-type; that is, they were the result of dicentric or centric ring aberrations. There were neither chromatid-type

Table 1

Experimental group	Percentage abnormal anaphases		
	15 min.	30 min.	60 min.
O_2	0	0	0
$O_3 + O_2$	10	29	42

figures nor sticky bridges, and all the deletions were double. There was good agreement between root tips in a particular experimental group ; for example, in the 60-min. contact group seven root tips were used for obtaining about 500 anaphase figures analysed, with a mean value of abnormal anaphases of 42 ± 1·6 per cent per slide.

Table 2 presents the results of ozone, X-rays, and ozone and X-ray treatments. 150 kV., 15 m.amp. unfiltered radiation was delivered at 50 r./min. as determined by an ionization meter. When the X-rays and ozone were combined, the oxone was administered first and the X-rays immediately after, so that the entire treatment required less than 25 min. The effects of ozone and X-rays were approximately additive.

Table 2

Experimental group	Dose	Percentage abnormal anaphass
O_2	60 min.	0
$O_3 + O_2$	30 min.	23
X-rays	100 r.	25
O_3 + X-rays	20 min. + 100r.	42

A small number of root tips from each group was treated with colchicine and an analysis made of metaphase aberrations. These observations confirmed that the aberrations were all of the chromosome-type (dicentrics and centric rings).

A more detailed report of this work will be published later. These investigations were supported by grant No. *R.G.* 4722 of the National Institutes of Health, U.S.A.

Use of Defoliants for drying Buckwheat in the Field, and a New Method for the Chemical Determination of Rutin

DEFOLIANTS are commonly used to facilitate the harvesting of cotton[1], beans, clover[2] and birdsfoot trefoil[3] for seeds, or for destroying the haulms of potatoes[4] to inhibit the spread of virus from infected leaves into the tubers. We thought it worth while to examine whether defoliants could be used for drying buckwheat (*Fagopyrum sagittatum* Gilib.), cultivated as medicinal plants, directly in the field, so as to avoid the tedious operations in connexion with artificial drying of the harvested material. As we expected that the rutin content might be influenced by defoliants, we have determined the rutin content of treated plants as compared with the control plants, cut and afterwards dried.

Table 1

Treatment	Rutin (per cent)	Quercetin (per cent)
Artificially dried plants	4·04	none
Sprayed with water alone and dried	3·62	0·10
0·1 per cent of sodium chlorate spray	3·60	0·18
1·0 per cent of sodium chlorate spray	2·68	0·24
2·0 per cent of sodium chlorate spray	2·30	0·27
1 per cent dinitrocresol (sodium salt) spray	2·20	none
10 per cent pentachlorophenol (sodium salt)	2·40	0·16

Buckwheat in full blossom was sprayed with several defoliants (see Table 1). Within five days 1 per cent sodium chlorate solution produced the most suitable drying of leaves, stalks and flowers among other defoliants used. Dried leaves were collected in a perfectly dehydrated form, leaving the empty stalks on the field (Fig. 1). The rutin content of the stalks, which is highest at the stage of bud formation and during that of flowering, is relatively small compared with that of the leaves[5].

The rutin content of the leaves was determined chemically. A new method was developed for this purpose, based on the colour reaction[6] of rutin with diazonium salts after its chromatographic separation[7]. 2·5 gm. of fresh leaves of buckwheat (or 0·25 gm. of dried material) is extracted in a Soxhlet apparatus for 90 min. with methanol (4 per cent pyridine was added when working with dried material) to determine

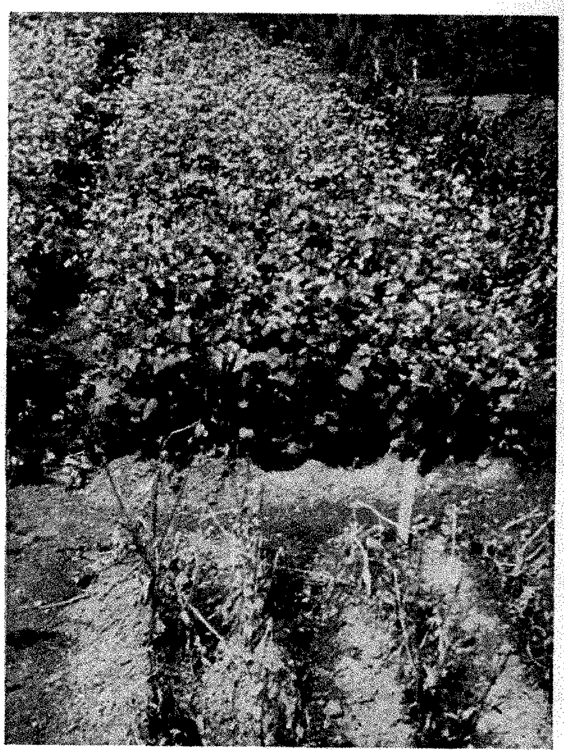

Fig. 1. Buckwheat five days after being sprayed with 1·0 per cent sodium chlorate solution and harvested (in front) and unsprayed (in background)

approximately the total flavonoids (phenolic compounds). An aliquot part (about 1 per cent) of the extract is evaporated to dryness, the rest dissolved in hydrochloric acid, a solution of diazotized sulphanilic acid is added and made alkaline with sodium hydroxide solution. The extinction is measured photometrically after 45 min. using a green filter (5330 A.), and the total flavonoids calculated from the graph for pure rutin.

A suitable quantity of the extract containing 200–300 μgm. of rutin (about 50–60 per cent of the total flavonoids) is chromatographed on Whatman No. 4 paper with 60 per cent aqueous acetic acid. The rutin spots are eluted with 0·1 *N* hydrochloric acid after detection in ultra-violet light and evaluated photometrically in the same manner as the total flavonoids. The quercetin content is estimated by comparison of the intensity of its yellow fluorescence in ultra-violet light with that of a progressive row of standard quercetin solutions chromatographed on the same paper.

We intend to investigate the effect of defoliation on other medicinal plants used not as drugs but as raw material in the pharmaceutical industry. A full account of this work will be published elsewhere.

Note added in proof. The leaves of buckwheat do not remain on the plants if they are not harvested within about seven days after treatment (depending on the weather), but it is hoped that the saving of labour and expense due to the use of this method compared with artificial drying may outweigh this disadvantage.

Recent experiments with defoliation of peppermint show a slow reduction of oil-content (from 1·53 per cent to 1·25 per cent—this difference being highly significant), but the leaves of peppermint plants remain on the stalks, in contrast to the behaviour of buckwheat.

Spot Chromatography Identification of Citrus Rootstocks

THE importance of knowing the variety of the rootstock in a citrus orchard is more than academic. The tolerance of an orange tree to infectious diseases; the size, the number and quality of its fruits; the palatability of its fresh and processed juice; its rate of growth and its expected longevity are all dynamically affected by the rootstock on which it is growing. Many of the citrus trees in California and elsewhere are growing on rootstocks the identity of which is not definitely known.

Methods for the chemical identification of citrus rootstocks have been published[1,2], and a paper chromatographic test for sour orange roots has been described[3,4].

This communication deals with a new method for the identification of the eight varieties of citrus rootstocks that are used commercially in California. The eight varieties are: sour orange (*Citrus aurantium* 'Brazilian'); grapefruit (*C. paradisi* 'Duncan'); sweet orange (*C. sinensis* 'Koethen'), tangelo 'Sampson', a hybrid of the tangerine 'Dancy' and grapefruit; mandarin (*C. reticulata* 'Cleopatra'); rough lemon (*C. limon*, considered by some to be a hybrid); trifoliate orange (*Poncirus trifoliata*); and 'Troyer' citrange, a bigeneric hybrid between navel orange (*C. sinensis*) and the trifoliate orange (*P. trifoliata*).

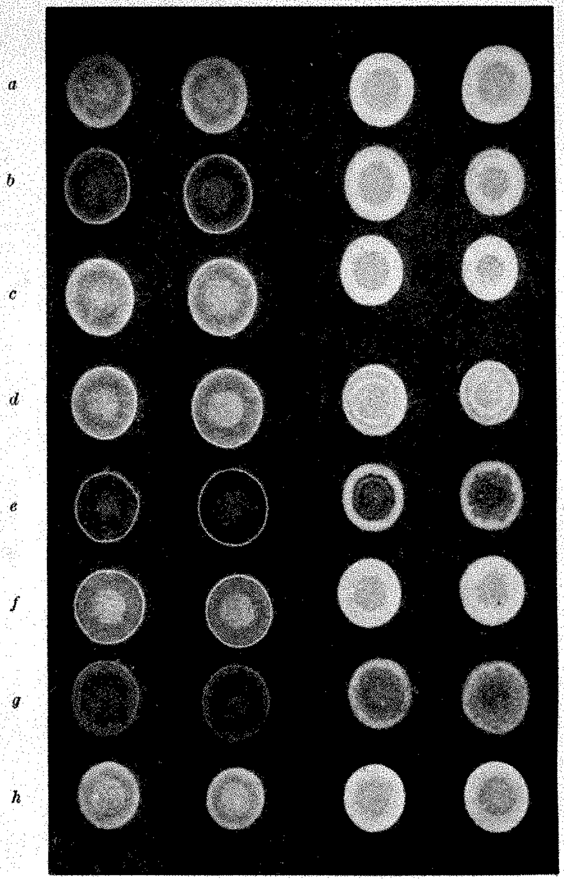

Fig. 1. The two lef -hand columns of spots are those made by dropping single drops of a plain 30-min. dimethoxypropane extraction of each root. The two right-hand columns of spots are from the 30-min. extractions to which anhydrous aluminium chloride was added and allowed to react for 30 min., before the spot was made. *a*, Sour orange (Brazilian); *b*, grapefruit (Duncan); *c*, sweet orange (Koethen); *d*, tangelo (Sampson); *e*, mandarin (Cleopatra); *f*, rough lemon; *g*, trifoliate; *h* citrange (Troyer)

The roots used were obtained from the experimental Valencia orange orchard of the University of California at Riverside, California, through the courtesy of Dr. W. P. Bitters. Each rootstock had been propagated by 'nucellar' seedlings. All the trees were thirty years old except for the Troyer citranges that were planted in 1944.

The method described here compares the spots made on filter paper by drops of extracts of unknown roots with similar spots made from known varieties. Under long-wave ultra-violet light (3650 A.) the spots fluoresce and display distinctive concentric yellow, brown and green circles. Fig. 1 indicates in black and white some of the distinguishing differences.

Of the thirty-three solvents tested, dimethoxypropane was the most satisfactory when used as described in (1) below. Complete identification of all of the rootstocks was not attained by using dimethoxypropane alone; so the extractions were subjected to reactions with salts of heavy metals. Of the thirty-six salts tried, anhydrous aluminium chloride, when used with dimethoxypropane, was the best. See (2) below.

(1) Freshly dug roots, $\frac{3}{8}$ in. diam. and larger, are washed free of dirt and wiped dry. The bark is cut through to the cambium and into pieces $\frac{1}{4}$ in. square and smaller. 10 gm. of the fresh bark are placed in a bottle. 15 ml. of 2,2-dimethoxypropane 98 per cent (Dow Chemical Co.) are added, and the mixture is allowed to stand for 30 min. at room temperature. Then single drops of the extraction are placed with a medicine dropper on a sheet of Whatman No. 1 filter paper. It will be noticed in Fig. 1 that the two left-hand vertical columns of spots represent the 30-min. extractions of the eight varieties of rootstocks. The two right-hand columns of spots were made by following the procedure described in the next paragraph.

(2) Arrange a series of clean, dry, 10 mm. × 75 mm. test-tubes, one tube for each rootstock. In each tube place 0·1 gm. of anhydrous aluminium chloride. This should be done ahead of time so that, immediately following step (1), 1·5 ml. of each of the 30-min. extractions may be added separately to 0·1 gm. of the aluminium chloride. Shake the tubes and allow them to stand for 30 min. At the end of that time single drops of the supernatant fluid in each test-tube are placed on the filter paper in the two right-hand columns. The spots should be allowed to dry thoroughly before comparisons are made between the known and unknown varieties.

The spots tend to deteriorate in a day or two. Precautions should be taken to prevent the spots on one sheet from spoiling those on other sheets which may be piled on top or below by inserting each sheet between a folded piece of wax-paper.

Unused roots may be kept for 2 or 3 days in plastic bags in a refrigerator at 4° C. or less. One batch of roots was kept in a food freezer at 0° C. for 34 months. The fluorescent spots of all of the varieties were within the usual range of colours except for the sweet rootstocks.

I wish to express my thanks to Dr. W. P. Bitters, Mr. Robert Hepler and Mr. James L. Jones.

Perceptual Stability of a Stroboscopically Lit Visual Field containing Self-Luminous Objects

IT is a familiar observation that when the retinal image is displaced as a result of an externally forced rotation of the eyeball (for example, by light sideways pressure with the finger), the visual world appears to move; whereas when the same rotation is produced voluntarily the visual world remains stable. This stability is often attributed to some (as yet unknown) process by which the effects of retinal change are thought to be accurately compensated or cancelled out during voluntary movement.

In the course of experiments designed to explore a different hypothesis[1], a rather striking phenomenon has been observed. If a room containing self-luminous objects (such as the cathodes of thermionic valves) is lit stroboscopically, it is found that at rates of flash down to some 15 per sec. the effects of pressing the eyeball intermittently (say, twice per sec.) and very lightly, are similar to those in ordinary light. At rates of some 5 or 6 per sec., however, a remarkable disparity is observed between the apparent motion of the self-luminous objects and that of the rest of the room. The glowing cathode of a valve, for example, appears to move whereas its envelope remains at rest, although surprisingly enough their relative positions can be clearly seen to be unaltered. A similar violent perceptual disturbance occurs with an artificial nystagmus, induced, for example, by first rotating the observer rapidly about a vertical axis with his eyes closed. The effect seems insensitive to level of illumination over the range used (0·3–3 Joules per flash), and has been described in similar terms by all of some fifty observers to date. To by-pass speculations invoking distortion of the eyeball, it may be said that the same disturbance occurs when the retinal image is displaced by moving a prism or mirror before the eye.

The apparent movement of the self-luminous objects would seem to be interpretable as the normal result of involuntary displacement of their retinal image, since that image is thrown continuously upon the retina. What is at first sight surprising (especially on any theory of 'compensation') is the relative stability of the stroboscopically lit room. It seems clear that a discontinuous displacement of the retinal image is not so powerful a stimulus for the perception of world-movement as when continuous motion produces the same displacement. If the eyeball is lightly pressed and held in its new position, the stroboscopically lit field is seen to move sluggishly to 'catch up' with the self-luminous objects, requiring several flashes to do so. The interesting conclusion suggested is that the magnitude of perceived movement is a function of the amount of information (in the technical sense) supplied by the retinal image, rather than of the magnitude of its displacement.

Two related observations seem to support this tentative conclusion. First, even in normal light the motion perceived during involuntary rotation of the eyeball seems to most observers to be greater in the central than in the peripheral parts of the field. This again suggests that the greater density of foveal information is transformed into a greater magnitude of perceived motion. Secondly, when a retinal image of radial lines (such as my 'ray' figure[2]) is involuntarily displaced, the normal apparent movement of the centre is accompanied by a fanwise movement of the rays lying nearest to the line of motion. The pattern appears to open out, as if on a distended rubber sheet, on the side away from which the centre moves, and to contract on the opposite side. The effect is suppressed if a line is drawn across the pattern at right angles to the rays concerned. The suggested inference is again that the magnitude of motion perceived is greater in those directions in which more information is generated by the retinal displacement.

The foregoing observations afford some encouraging confirmation of the hypothesis I have put forward[1]—this having, for once, had the good fortune to be advanced ahead of them on theoretical grounds. Briefly, the argument is that if perception is the adaptive 'keeping up to date' of an organism's state of organization for activity in its world[3], then what requires informational justification is not the maintenance of stability but the perception of change. The internal state of organization, which implicitly represents the perceived world, should remain unaltered unless sufficient information (in the technical sense) arrives to justify a change, by indicating that the current state of organization is significantly mismatched to the state of affairs sampled by the receptor system[4].

Thus the retinal changes resulting from voluntary movement evoke no perception of world-motion, because they are not an awkward consequence to be compensated, but part of the goal to be achieved. If these changes are prevented from occurring, for example by stabilizing the retinal image, the absence of retinal change evokes an impression of movement.

From this point of view, all the anomalies reported above make some sense as evidence that: (*a*) perceptive activity is relatively detached from that of the receptor system; (*b*) in sampling the receptor field, the perceptive system is relatively insensitive to the position of the image, and demands a combination of evidence exceeding some 'threshold of significance' before it responds by the perception of a change; (*c*) the strength of the impression of change depends on the total amount of information validating a change in the state of organization—in other words, it depends on the informational weight attached to discrepant samples from the receptor system; (*d*) the change perceived, however surprising to the observer, is always the most parsimonious which will match the discrepant information; perception would appear to be organized on the conservative principle of a null-hypothesis.

Sub-aerial Volcanicity in Snowdonia

Extensive recent work in south-central Lleyn (F. J. F.), Beddgelert (N. R.) and the pass of Llanberis (F. J. F. and N. R.), supplemented by observations from the pass of Aberglaslyn (R. V. B.) warrants a new interpretation of Snowdonian volcanics of mid-Ordovician age.

It appears now that the acid volcanics of Snowdonia exhibit many phenomena found in areas where recent volcanicity has been in progress (for example, New Zealand, Alaska). Four main features of Snowdonian volcanics are worthy of emphasis. (1) The bulk of the volcanics consist of ignimbrites or welded tuffs. A wide variety of these rocks are found ranging from fine dusty varieties (National Grid No. $SH_{(2)}576_{(3)}509$) to coarse welded agglomerates ($SH_{(2)}632_{(3)}563$). The general absence of bedding and the widespread presence of flattened vesicles in these rocks is suggestive of sub-aerial rather than submarine deposition of the glowing avalanches. Frequent vertical explosive shoots and tuff pipes traversing the ignimbrites are now recognized (for example, $SH_{(2)}593_{(3)}525$). The tuff pipes are probably produced by fumarolic action similar to that recorded from the Valley of Ten Thousands Smokes, Alaska.

(2) In many cases extrusion of basic lavas preceded the deposition of welded tuffs. Well-preserved top surfaces of ropy lava have been found suggesting that the top of the flow was sub-aerial. Since these lavas are often blocky or even pillowy at their lower boundary, where they are often mixed with muddy sediments, a transition from sub-marine to sub-aerial conditions must have taken place during their extrusion. The basic lavas have been mapped by H. Williams[1] as deformed dolerites.

(3) The acid deposits often contain rocks previously called 'the nodular rhyolites'. There are several varieties of 'nodular rhyolites', each originating in a different way. For example, some of the so-called 'nodular rhyolites' near Beddgelert are spherical bodies of medium grain welded tuff in a matrix of a fine grain welded tuff.

(4) Near Pont y Gromlech in the pass of Llanberis a volcanic centre has been recently identified. West of Pont y Gromlech a vent of agglomerate ($SH_{(2)}623_{(3)}565$) traverses the grits and slates of the Gwastadnant Group terminating in the Lower Rhyolite Tuff. Hereabouts, the main volcanic sequence is underlain by deposits consisting of large boulders of grit, slate and volcanic material in muddy or silicified matrix. These deposits seem to represent mud-flows (lahars), which preceded the main Snowdonian ignimbrites.

The presence of welded tuffs in Snowdonia was first recorded by Oliver[2], who identified as such a thin section from Capel Curig. Our work suggests that the bulk of Snowdonian acid volcanics are welded tuffs with subsidiary basic lavas. If so, then the thickness of such deposits has no direct bearing on the proximity to the volcanic centres, since the modern welded tuffs are known to thicken in the pre-existing topographic hollows (for example, see Enlows[3]). That the main Snowdonian ignimbrites were deposited on an irregular surface possessing such hollows has been now proved by detailed mapping of the well-exposed lower boundary of the Lower Rhyolite Tuff near the Pen-y-pass Hotel, Pass of Llanberis.

In so far as their mode of extrusion is concerned, accumulating evidence suggests that the Snowdonian volcanics were derived from numerous small sub-aerial explosive vents, such as have been recognized in the Pass of Llanberis and in Lleyn. These vents are associated with intrusive rhyolites but, contrary to Matley's[4] opinion, not with granophyre or micro-granite intrusions.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, February 17

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. A. Stephenson: "Surveying and the Modern Expedition".

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. S. Rees Jones: "The Painter's Eye—a Talk on Science and Painting".

University of London (at Birkbeck College, Malet Street, London, W.C.1), at 5.45 p.m.—Dr. J. A. Kitching: "Physiological Mechanisms in the Protozoa".* (Further lectures on February 19 and 21.)

Society of Chemical Industry, Pesticides Group and Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. R. J. Courshee: "Corrosion of Spraying and Dusting Machinery".

British Computer Society (at York Hall, Caxton Hall, Westminster, London, S.W.1), at 6.15 p.m.—Prof. A. C. Aitken: "Mental Arithmetic, an Historical Review with Demonstrations".

Institute of Metal Finishing (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 6.30 p.m. —Mr. A. R. Thompson: "Health Hazards Associated with Metals Affecting the Finisher".

Society of Cosmetic Chemists of Great Britain (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.30 p.m.—Mr. W. C. Botfield: "Perfumery".

Tuesday, February 18

Bedford College (at Regent's Park, London, N.W.1), at 5.15 p.m. —Dr. W. Grey Walter: "The Physiology of Mentality".*

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. C. A. G. Wiersma (California Institute of Technology): "Comparative Physiology of Crustacean Neuro-Muscular Systems".*

Imperial College (in the Main Chemistry Lecture Theatre, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Prof. F. D. Richardson: "The Changing World of the Extraction Metallurgist" (Inaugural Lecture).

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. J. E. Flood: "Electronic Devices in Telephony".

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. H. C. Husband: "Jodrell Bank Radio Telescope".

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. C. D. Mee: "Magnetic Tape for Data Recording".

Society for Analytical Chemistry, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Meeting on "Solid Source Mass Spectrometry".

Oil and Colour Chemists' Association (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. F. Schollick: "Some Aspects of Amino Coating Resins".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. E. G. Broadbent: "Aeroelastic Problems associated with High Speeds and High Temperature".

Wool Education Society (at the Royal Institution, 21 Albemarle Street, London, W.1), at 7 p.m.—Mr. H. B. Carter: "Science and the Wool Grower".

British Glaciological Society (joint meeting with the Challenger Society, at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Dr. Erkki Palosuo: "Sea Ice Prediction Techniques in the Baltic".

Wednesday, February 19

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. J. E. P. Dunning: "Rocket Propulsion".

Eugenics Society (at Manson House, 26 Portland Place, London, W.1), at 5 p.m.—Prof. Aubrey Lewis: "Fertility and Mental Disorder"* (Galton Lecture).

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. G. A. Corby and Mr. J. A. Sawyer: "The Air Flow Over a Ridge—the Effects of the Upper Boundary and High-level"; Mr. C. E. Wallington and Mr. J. Portnall: "A Numerical Study of the Wave-length and Amplitude of Lee Waves".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Prof. M. G. Kendall: "Research in Statistics".

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Sir Christopher Hinton, F.R.S.: "Nuclear Power Development—Some Experiences of the First Ten Years"* (Melchett Lecture for 1957).

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. L. C. Jesty: "The Relation Between Picture Size, Viewing Distance and Picture Quality with special reference to Colour Television and to Spot Wobble Techniques".

Institute of Physics, London and Home Counties Branch (at 47 Belgrave Square, London, S.W.1), at 6 p.m.—Annual General Meeting, followed by Dr. A. H. Willbourn: "High Polymer Properties and Structure".

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Scientific Papers.

Royal Institute of Chemistry, London Section (at the Royal Institution, 21 Albemarle Street, London, W.1), at 6.30 p.m.—Prof. Arne Tiselius, For.Mem.R.S. (University of Uppsala): "Purity and Purification of Chemical Substances" (First Humphry Davy Lecture).

Society for Analytical Chemistry, Biological Methods Group (in the restaurant room of "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting on "The Stage at which a Biological Assay Can be Replaced", introduced by Mr. W. L. M. Perry.

Thursday, February 20

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. R. E. Peierls, F.R.S., Dr. D. H. Wilkinson, F.R.S., and Prof. W. E. Burcham, F.R.S.: "Recent Advances in Nuclear Physics".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—General Meeting.

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. W. Milnor: "Groups Which Act on S^n Without Fixed Points".

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. J. H. Welch: "Direct Observation of High-Temperature Processes with the Microscope".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Prof. B. S. Platt: "Malnutrition and Pathogenesis of Zymotic Diseases".

Friday, February 21

British Psychological Society, Industrial Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Dr. N. H. Mackworth: "The Television Eye-marker" (Chairman's Address).

Institute of Physics, Applied Spectroscopy Group (at 47 Belgrave Square, London, S.W.1), at 3 p.m.—Meeting on "X-Ray Fluorescence".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "The Transition from the Ionosphere to Interplanetary Space". Chairman: Mr. J. A. Ratcliffe, F.R.S. Speakers: Prof. Sydney Chapman, F.R.S., Dr. D. E. Blackwell, Dr. J. V. Evans and Dr. A. Hewish.

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5.15 p.m.—Air Commodore R. T. Gething, O.B.E., A.F.C.: "Air Search and Rescue Problems".

British Institute of Radiology, incorporated with the Röntgen Society (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 5.30 p.m.—Papers on "Recent British Gamma Ray Beam Units". Speakers: Mr. T. Ashton, Mr. G. S. Innes, Mr. R. G. Wood, Dr. J. R. Clarkson and Mr. J. C. Jones.

North East Coast Institution of Engineers and Shipbuilders, (in the Lecture Theatre of the Mining Institute, Neville Hall, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. D. Firth: "The History and Development of Hydraulic Transmissions for Marine Propulsion".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Alexander Haddow: "Cancer Research—Its History and Prospects".

Saturday, February 22

Association of Clinical Biochemists, Southern Region (at King's College Hospital Medical School, Denmark Hill, London, S.E.5), at 2 p.m.—Scientific Papers. 4.15 p.m.—Demonstrations by Staff of the Department of Chemical Pathology, King's College Hospital.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Principal Lecturer (with high qualifications in physiology and preferably some experience as a university lecturer) in Anatomy and Physiology—The Principal, Loughborough Training College, Loughborough (February 21).

Assistant Lecturer or Lecturer in Applied Mathematics—The Secretary, The University, Exeter (February 22).

Scientific Officer (with an honours degree in zoology) in the Nematology Department—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (February 22).

Assistant Lecturer in Organic Chemistry; an Assistant Lecturer in Pure or Applied Mathematics; and an Assistant Lecturer in Physics—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (February 28).

Assistant Lecturers (2) (honours graduates, with some research experience in physical, inorganic or physical-organic chemistry) in Chemistry—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (February 28).

ENTOMOLOGIST (with a good honours degree and a keen interest in applied entomology), to develop and apply laboratory techniques for investigating the biological activity of insecticides and spray deposits —The Secretary, East Malling Research Station, near Maidstone, Kent (February 28).

SENIOR LECTURER IN MEDICINE at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, February 28).

CONSULTANT BIOMETRICIAN (fully qualified) with the Government of the Federation of Rhodesia and Nyasaland, for duties which include the design of experiments in all phases of agriculture and animal husbandry research and the analysis of data and related statistical practice—The Secretary (R), Rhodesia House, 429 Strand, London, W.C.2 (March 1).

SENIOR LECTURER or LECTURER IN THE DEPARTMENT OF SURGICAL SCIENCE—The Secretary, The University, Edinburgh (March 1).

LECTURER or ASSISTANT LECTURER IN THE HISTORY AND PHILOSOPHY OF SCIENCE—The Registrar, The University, Leeds 2 (March 10).

CHAIR OF EDUCATION in the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 12).

ASSISTANT LECTURER IN ORGANIC CHEMISTRY—The Secretary, The Queen's University, Belfast (March 15).

ASSISTANT LECTURER (with a special interest and qualifications in petrology, and research experience, preferably in either geochemistry, ore mineralogy or structural geology) IN GEOLOGY—The Secretary, University College, Gower Street, London, W.C.1 (March 15).

CHAIR OF GEOLOGY—The Secretary and Registrar, The University, Southampton (March 15).

LECTURER IN AGRICULTURAL ENTOMOLOGY at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 15).

LECTURER IN NATURAL PHILOSOPHY—ELECTRONICS—The Secretary, The University, Aberdeen (March 15).

PROFESSOR AND HEAD OF THE DEPARTMENT OF GEOLOGY at the Memorial University of Newfoundland, St. John's, Newfoundland, Canada—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Canada, March 15).

IMMUNOLOGIST (graduate in either science or medicine and with a sound knowledge of immunology) IN THE DEPARTMENT OF SURGICAL SCIENCE, to work on problems of transplantation immunity under the general direction of the Professor—The Secretary, The University, Edinburgh (March 31).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY, CIVIL ENGINEERING or PHYSICS—The Registrar, Trinity College, Dublin (March 31).

PROFESSOR OF PREVENTIVE AND SOCIAL MEDICINE at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, March 31).

ASSISTANT, Grade B (with a good honours degree) FOR MATHEMATICS—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex.

ASSISTANT LECTURER IN METALLURGY IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Principal, Royal Technical College, Salford 5.

ASSISTANT LECTURER IN PHYSICS—The Registrar, The University, Nottingham.

ASSISTANT (preferably with experience of biochemical or genetic techniques in microbiology) for research on the mode of action of antituberculous drugs—The Secretary, Guy's Hospital Medical School, London Bridge, S.E.1.

ASSISTANT SEISMOLOGIST (with an honours degree in physics or in geology with physics to degree standard, and preferably with research experience in geophysics) at the Imperial College of Tropical Agriculture, Trinidad, British West Indies—The Secretary, I.C.T.A., 40 Norfolk Street, London, W.C.2.

CHEMISTS (with an honours degree), to join a team working on the surface chemistry of carbon and graphite, particularly in relation to the reactivity of these materials with gaseous coolants at elevated temperatures—The Recruitment Officer (1022/34), Atomic Energy Research Establishment, Harwell, Didcot, Berks.

EXPERIMENTAL OFFICER (with a degree in chemistry or agricultural chemistry, or equivalent qualifications), to carry out chemical analyses of soils and plants—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

HARWELL RESEARCH FELLOWS (JUNIOR and SENIOR) (with at least two or three years postgraduate experience), for research in Chemistry, Mathematical Physics, Chemical Engineering, Physics, Metallurgy, Biochemistry and Food Technology—Group Recruitment Officer (1053/2), Atomic Energy Research Establishment, Harwell, Didcot, Berks.

HOSPITAL BIOCHEMIST (Senior grade)—The Group Secretary, Cardiff Hospital Management Committee, 44 Cathedral Road, Cardiff.

PROTEIN CHEMIST or PHYSICIST (preferably Ph.D. or with equivalent research experience), to work on immunological problems—The Secretary, The Wright–Fleming Institute of Microbiology, St. Mary's Hospital Medical School, Paddington, London, W.2.

READER IN WOOL TECHNOLOGY; READER IN MAN-MADE FIBRES AND TEXTILE CHEMISTRY; READER IN HIGH POLYMER CHEMISTRY; READER IN COLOUR CHEMISTRY; READER IN MECHANICAL OR PRODUCTION ENGINEERING; READER IN ELECTRICAL ENGINEERING; and a READER IN PHARMACEUTICS—The Principal, Institute of Technology, Bradford 7.

SCIENTIFIC OFFICER (with a good honours degree in natural science, preferably zoology, with two years postgraduate training or experience in scientific research) IN THE JOINT FISHERIES RESEARCH ORGANIZATION, Northern Rhodesia, to undertake research as may be required into any aspect of freshwater biology, fish and fisheries in Northern Rhodesia and Nyasaland—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.87/3/01.

SENIOR CHEMISTRY MASTER—The Headmaster, Malvern College, Worcs.

SENIOR LECTURER IN MATHEMATICS; SENIOR LECTURER IN PHYSICS; SENIOR LECTURER IN INDUSTRIAL ADMINISTRATION; SENIOR LECTURERS (2) IN PHARMACEUTICS; SENIOR LECTURER IN PHARMACOLOGY; LECTURER IN CHEMICAL ENGINEERING; LECTURERS (2) IN CIVIL ENGINEERING; and a LECTURER IN PHYSICS—The Principal, Institute of Technology, Bradford 7.

VICE-PRINCIPAL (with good academic qualifications and administrative experience, preferably in advanced technological education) —The Principal, Institute of Technology, Bradford 7.

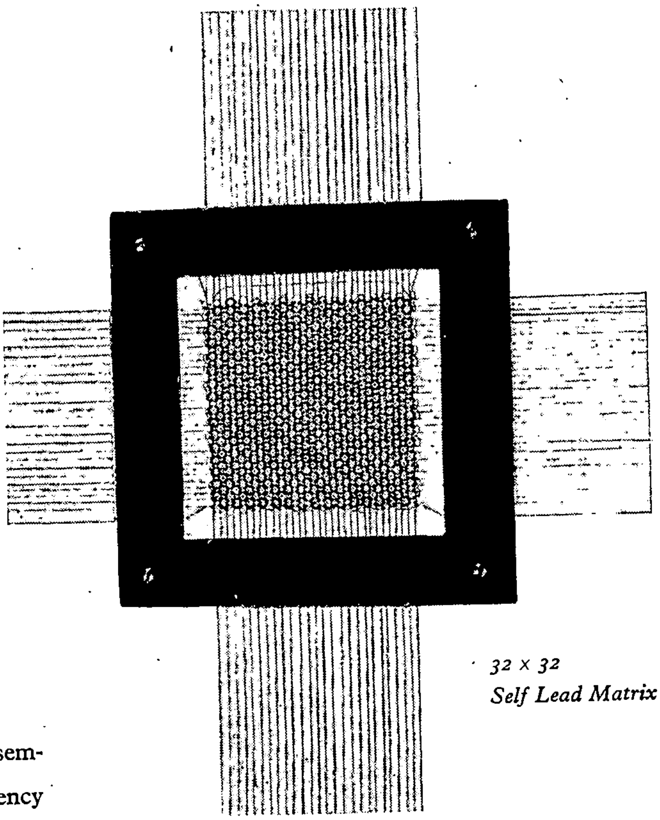
Formula for Computer Efficiency...



32 x 32
Self Lead Matrix

'FERRAMIC' FERRITE CORES AND ASSEMBLIES

Plessey 'Ferramic' Square Loop Ferrite Cores and Assemblies ease design problems and ensure maximum efficiency in high speed digital computers. They are available in two types of graded material—designated S1, and S3.

'Ferramic' S1 material is notable for the tight limits to which top-grade cores are 100% tested, for high operating speeds, high output voltages on switching, and low values of noise voltage output.

'Ferramic' S3 material obviates the need for ultra-small cores where lower operating current is used and where the high speeds of S1 material are not required.

Cores in 'Ferramic' S1 and S3 are now available in *eight sizes* ranging from 0.050″ to 0.375″ o.d.

Matrix Stores These can be made to customers' designs, or Plessey preferred patterns can be supplied. Plessey specialise in transistor driven types using 0.050″ o.d. cores.

Transfluxors Multi-aperture cores are available for flip-flop circuits, non-destructive read-out stores and many other applications.

Logical and Switching Units Available in S1 or S3 material as required by customers. As many as ten windings with a total of 400 turns can be provided on 0.120″ o.d. cores. All units are encapsulated in Polyester or epoxy resin with terminations as required.

The Company's Technical Representatives will gladly discuss Design Engineers' requirements and invite applications for samples, and of course publications:- Data Sheet 6044 ('Ferramic' S1 Square Loop Ferrites); Advance Information Sheet 936 ('Ferramic' S3 Square Loop Ferrites); and Advance Information Sheet 938 (Magnetic Memory Planes).

LECTURES AND COURSES

UNIVERSITY OF LONDON KING'S COLLEGE

CHEMICAL ENGINEERING

Applications for places next October in the postgraduate one-year course for the College Diploma should reach the Registrar, from whom particulars and forms may be obtained, by March 15.

The College offers Shell Studentships of the value of £375, with free tuition and examination fees. Applications for these should also be in by March 15.

This course is approved by the D.S.I.R. for Advanced Course Studentships. Applicants interested in these should inform the Registrar of the College by February 24.

King's College London,
Strand, W.C.2.

WELSH COLLEGE OF ADVANCED TECHNOLOGY

CATHAYS PARK, CARDIFF

ASSOCIATESHIP SANDWICH COURSE IN APPLIED PHYSICS

A four-year Sandwich Course, leading to a College Associateship, will commence in October, 1958. The Institute of Physics has approved this course, and the Associateship will satisfy completely the Institute's academic requirements for Graduateship and corporate membership. Students may be " works " or " college " based, and will spend alternate six-monthly periods in college and industry. Normal requirements for admission to the course will be success at G.C.E. " A " level or O.N.C. at a high standard in applied physics or electrical engineering.

Details of the course may be obtained from, and applications should be made to, the Principal.

R. E. PRESSWOOD,
Clerk to the Governors.

UNIVERSITY OF LONDON: A LECTURE entitled " Some Studies on Non-benzenoid Aromatic Compounds " will be delivered by Dr. E. Hellbronner (Zürich) at 5.30 p.m. on February 24 at University College (Chemistry Lecture Theatre), Gower Street, W.C.1. Admission free, without ticket.—James Henderson, Academic Registrar.

GRESHAM LECTURES. DR. W. H. Steavenson, P.R.A.S. (Gresham Professor in Astronomy) will deliver a course of four Lectures entitled " The Stars and the Universe " on Monday to Thursday, February 17 to 20, at Gresham College, Basinghall Street, E.C.2. Tel. MONarch 2433.—The Lectures are free and begin at 5.30 p.m.

OFFICIAL APPOINTMENTS

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF PHYSICS

Applications are invited for appointments as Lecturer, Assistant Professor, Postdoctorate Fellow and Research Assistant in the Department of Physics. The vacancies have been created by the rapid expansion of the university. They are mainly in the fields of nuclear physics, optical spectroscopy, solid state physics and geophysics. Applicants should have an honours degree in physics and, except in the case of Research Assistants, a Ph.D. degree. They should not be more than 30 years of age and should be available in September, 1958. There are also Teaching Assistantships available to help students who wish to pursue graduate work towards a Ph.D. degree.

Applicants wishing fuller information regarding any of these positions or awards should write to G. M. Shrum, Head, Department of Physics, University of British Columbia, Vancouver, B.C., Canada.

SCUNTHORPE HOSPITAL MANAGEMENT COMMITTEE

RADIATION MONITORING SERVICE

Vacancy for Technician or Technician in Training. Work mainly concerned with radiation measurement to ensure safe working conditions in X-ray and Therapy Departments of Lincolnshire Hospitals. Qualification for Technician in engineering or appropriate apprentice including experience in applied physics or design of instruments or O.N.C. in approved subjects, minimum age 21. Salary scales: Technician, £475 to £600 ; Trainee, £155 at age 16 rising to £380 at 25 or over. Whitley Council conditions of service.

Application form from Group Secretary, War Memorial Hospital, Scunthorpe.

NATIONAL RESEARCH DEVELOPMENT CORPORATION

requires an honours graduate in biology or chemistry, with thorough training in formal genetics, for research work in microbial genetics at the Ministry of Supply's Microbiological Research Establishment at Porton.

Starting salary would be within the scale for Senior Scientific Officers or that for Principal Scientific Officers in the Civil Service, according to which seemed the more appropriate to age, qualifications and experience.

Initially the person appointed would be required to lead a small team in the study of the genetics of micro-organisms of value in the fermentation industry, particularly the organisms used in antibiotic production. This work would be conducted under the auspices of the Corporation and is expected to take two years. During that period or at its termination he would, subject to satisfactory work and suitability in other respects, be considered for employment at Porton by the Ministry of Supply ultimately on research in the broad field of microbial genetics.

Apply, in confidence, to N.R.D.C., 1 Tilney Street, London, W.1.

UNIVERSITY OF EDINBURGH

DEPARTMENT OF SURGICAL SCIENCE

IMMUNOLOGIST

Applications are invited for the post of Immunologist in the Department of Surgical Science, to work on problems of transplantation immunity under the general direction of the Professor. Applicants should be graduates in either science or medicine and have a sound knowledge of immunology. The successful applicant, who will be given the status of either Lecturer or Senior Lecturer according to qualifications and experience, will be expected to give some postgraduate instruction in experimental methods and may also be called upon to supervise research students but will have no other teaching duties. If the person appointed is given the status of Senior Lecturer the salary scale will be £1,950 by £100 to £2,550 per annum ; if the status of Lecturer the scale will be £900 by £100 to £1,300 ; Bar: £1,400 by £100 to £1,900 with placement according to qualifications and experience. The post is subject to superannuation and family allowance is payable where applicable.

Further particulars may be obtained from the undersigned, with whom applications (six copies), giving the names of two referees, should be lodged not later than March 31, 1958.

CHARLES H. STEWART,
Secretary to the University.

WAR OFFICE REQUIRES TWO EXPERIMENTAL Officers (male) at Royal Military College of Science, Shrivenham, Berks., in Engineering Physics Branch of Department of Instrument Technology. Qualifications: Degree in engineering or physics or H.N.C. in electrical engineering or applied physics or equivalent and preferably with practical experience in instrumentation or servomechanisms or computing. Knowledge of electronics an advantage. Salary: £920 to £1,130. Starting pay according to age and experience. Age at least 26 years. Good prospects of permanency.—Particulars and forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting reference A.23/8A. Closing date February 28, 1958.

A POST IS AVAILABLE AT THE REGIONAL Thoracic Surgical Centre, Hill Top Hospital, Bromsgrove for a Biochemist (Basic Grade) in the Cardio-Respiratory and Biochemistry Department. —Applications, within ten days of the appearance of this advertisement, together with the names of two referees, should be sent to the Hospital Secretary, from whom further information may be obtained.

UNIVERSITY OF EDINBURGH AND HERIOT-WATT COLLEGE

JOINT DEPARTMENT OF CHEMICAL TECHNOLOGY AND CHEMICAL ENGINEERING

Applications are invited for either a Lectureship or an Assistantship. Lectureship: the initial salary will be at a point on the scale £900 to £1,650 per annum, according to qualifications and experience. It is hoped to appoint a man who will be active in some field of chemical engineering research of his own choice. Assistantship: the initial salary will be in the range £700 to £850 per annum. Teaching duties will not be heavy and the Assistant may engage in research for a Ph.D. Both posts are subject to superannuation, and family allowance will be payable where applicable. The successful applicant will be expected to take up duty on October 1, 1958. Applications will be considered from chemical engineers, physicists, chemists or mechanical engineers, or from mathematicians who have experience in applied science.

Further particulars may be obtained from the undersigned, with whom applications (four copies), giving the names of two referees, should be lodged not later than March 24, 1958. (A candidate from overseas may submit one copy of this application.)

CHARLES H. STEWART,
Secretary to the University.

MAKERERE COLLEGE

THE UNIVERSITY COLLEGE OF EAST AFRICA

Applications are invited for (a) Lectureship or (b) Assistant Lectureship in Agricultural Botany. Salary scales: (a) £1,107 by £42 to £1,149 by £45 to £1,284 by £51 to £1,335 by £54 to £1,389 by £57 to £1,617 per annum ; (b) £939 by £42 to £1,065 per annum. Entry point determined by qualifications and experience. F.S.S.U. Child allowance £50 per annum per child (maximum £150 per annum). Passages for appointee and family (up to four adult passages) on appointment, termination, and leave (three months every 21 months). Rent according to quarters provided, £45 to £84 per annum (including basic furniture).

Detailed applications (six copies), naming three referees, by March 31, 1958, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

GOVERNMENT OF NORTHERN IRELAND

Applications are invited for pensionable post of Scientific Officer in Plant Breeding Division, Ministry of Agriculture, Loughgall, Co. Armagh. Candidates must be British subjects normally resident in the United Kingdom and possess a honours degree in agriculture or agricultura botany (or equivalent qualification) with sound knowledge of the principles of genetics and practical plant breeding. Previous experience in design and analysis of field trials will be an advantage Salary scale £615 to £1,080. A candidate with special qualifications and experience may b offered a salary above the minimum. Women' scale is slightly lower but will reach equality with men's scale in 1961. Preference will be given to ex-Service candidates.

Application forms obtainable from Secretary, Civil Service Commission, Stormont, Belfast. Completed forms, with copies of two recent testimonials, must be returned by February 25, 1958.

UNIVERSITY OF KHARTOUM

Applications are invited for the Chair of Physics. Salary, £S.2,760 per annum. Cost of living allowance approximately £S.100 per annum. Outfit allowance £S.50. Family allowances: wife, £S60 per annum ; first child, £S.90 per annum ; second and third child, £S.30 per annum each. (£S.1 = £1 0s. 6d. sterling.) Passages for appointee and family on appointment, termination and annual leave. Superannuation scheme. Appointment on contract for five years.

Detailed applications (eight copies), naming three referees, by April 15, 1958, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

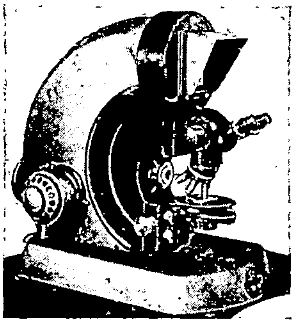
UNIVERSITY OF LIVERPOOL

Applications are invited for a suitably qualified technician to take charge of the teaching laboratories in the Department of Physics. The appointment will be made at an early date. It is hoped that a new physics building will be ready for occupation at the beginning of Session 1959/60.

Applications, in writing, stating experience and qualifications, together with the names of two referees and quoting Reference No. 220, should be sent to the Registrar, the University, Liverpool, 3.

The remarkable Carl Zeiss

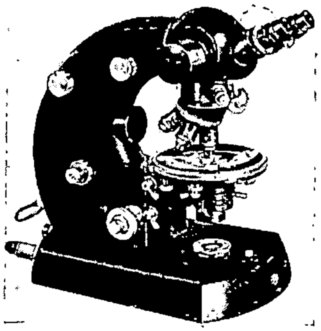
Ultraphot II **Photomicroscope**



The only photomicrographic microscopes with automatic exposure control for both epi- and trans-illumination.

Just arrived in this country, these instruments are now available for demonstration.

New descriptive booklet available on request.



IN SCOTLAND. The Ultraphot II, the Photo-microscope and a range of other Zeiss microscopes and industrial measuring equipment will be shown in Glasgow at St. Enoch Hotel on March 3 and 4, and in Edinburgh at the showrooms of Messrs. Butterworths (Edinburgh), Ltd., 14 Thistle St., Edinburgh, on March 6 and 7 next.

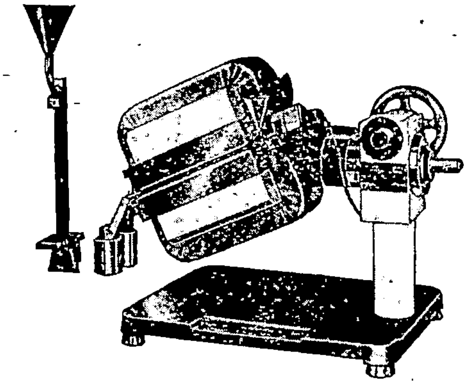
MAGNETIC SEPARATOR



The Magnetic Separator used by the British, Commonwealth and Foreign Government Departments, University and Commercial Laboratories all over the World.
Separations of at least 99% purity easily obtained even in certain instances when the specific gravities of the minerals are so close that they cannot be separated by the Centrifuge.
Standard Instrument includes a non-magnetic Vibrating pan with feed-hopper and collecting pans. Can also be supplied with Vertical bulk separation attachment shown above at side of Separator.

Send for particulars.

MUFFLE FURNACES

FOR GENERAL PURPOSES
MAXIMUM TEMPERATURE 1000°C. ENTIRELY SELF-CONTAINED

- Modern, clean appearance with built-in control equipment.
- Cases made of asbestolite panels which ensure maximum resistance to corrosion and present smooth external surfaces.
- High quality wire-wound elements, external to the muffles and hence protected from fumes and gases arising inside the furnace during operation.
- Uniform temperature and low power consumption.
- All furnaces protected by a temperature fuse.
- Removable panel permits easy access for renewal of heating elements in the event of failure.

Send for catalogue No. 558A giving full details of our complete range of laboratory furnaces.

CASELLA LONDON

A NEW INSTRUMENT FOR SAMPLING AIRBORNE DUST—

THE HEXHLET

This instrument enables a bulk sample of the 'respirable' fraction of a dust cloud to be collected for subsequent chemical analysis. It employs a horizontal elutriator consisting of a number of flat horizontal ducts through which air is drawn at a constant velocity, such that particles above about 7μ will settle out before reaching the end. The air flow is maintained constant by means of a 'critical orifice'. Suction is provided by an air ejector. The respirable fraction of the dust is collected in a Soxhlet filter thimble which will hold up to 2 grammes of dust before its resistance becomes too high.

DISLOCATIONS AND MECHANICAL PROPERTIES OF CRYSTALS

Edited by

J. C. Fisher; W. G. Johnston; R. Thomson; T. Vreeland, Jr.

This work grew out of a small international conference, held in New York late in 1956, and sponsored by the Air Force Office of Scientific Research, Air Research and Development Command and the General Electric Research Laboratory. The book presents in a very complete manner the principal methods for observing individual dislocations. It reviews the parts of the field which are most complicated so that the present state of the subject is made quite clear.

Size: 9¼" × 6" *648 pages* *Illustrated* *120s. net*

HEAT TRANSFER

(Volume II)

by

Max Jakob

In the second volume of this classic work, the author deals mainly with selected fields of heat-transfer applications. He also offers a comprehensive analysis and discussion of heat radiation in spaces of simple configuration. A special feature is the inclusion of a section entitled "Supplements to Volume I", bringing up to date some of the material in that volume which needed additions or modifications as a result of later developments.

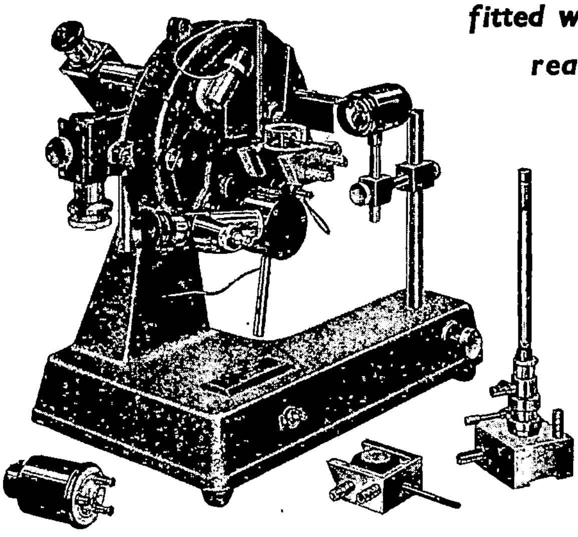
37 ESSEX STREET, LONDON, W.C.2

PRECISION INSTRUMENTS

Pulfrich Refractometer



fitted with circle divided on glass and giving readings on opposite sides of the circle to 5 seconds, by double microscope

This instrument possesses many advantages over the older type of Pulfrich refractometer and is used in all parts of the world for testing oils, optical glass, chemicals, drugs, etc.

We shall be pleased to demonstrate this instrument and give any advice as to its use, by appointment at our Works.

SCIENTIFIC MANAGEMENT IN NATIONALIZED INDUSTRIES

LORD SIMON OF WYTHENSHAWE'S pamphlet, "The Boards of Nationalized Industries"*, arises out of his experience as governing director of two private engineering firms and as chairman of the British Broadcasting Corporation. It is a noteworthy contribution to the objective discussion of the nationalized industries which party politics have hitherto largely denied. The pamphlet expounds Lord Simon's conviction that the most important single reform in the nationalized industries is that the chairman and other members of the Board should have the same kind of experience, independence and security of tenure as is common in the best concerns of private enterprise ; but it is of wider importance as endorsing the stress laid on the quality of management in the recent reports of the Fleck Committees dealing with the Atomic Energy Authority, to which reference has already been made in these columns (see *Nature*, February 15, p. 439).

The first of those reports stressed the over-riding importance of a suitable organization for recruitment, training and progression of promotion of technical staff and of a positive policy of selection of promising men at an early stage in their careers, followed by planned training on the job by moving them from one part of the organization to another. That policy should be designed to provide managerial staff with a sound understanding of all the main aspects of the organization's work, and while the report outlines in some detail general principles of organization which should govern a large technological production group, it repeatedly stresses the need for some scientific and technical knowledge on the part of those holding the highest managerial posts. The question of management is thus put right in the context of the shortage of scientific and technical man-power and of Britain's need to expand as a matter of urgency both technological and scientific education as well as to modify it to provide men of the qualities needed. The report of the second committee dealing with nuclear safety points no less emphatically to the shortage of technical staff in this field at all levels, though the emphasis is not so much on the management side.

Lord Simon comes out as emphatically as the well-known report of the Fleck Committee on the organization of the National Coal Board as to the vital importance of the quality of leadership at the highest level, and the need for encouraging the development of people capable of filling those positions. The most important single quality in the successful conduct of any large concern, whether public or private, is the quality of the highest authority in it, and Lord Simon's careful comparison of the board of Imperial Chemical Industries, Ltd., with the National Coal Board is intended to throw into relief the strength and weakness of the two boards and the way they are selected, and especially to suggest means by which the National Coal Board could be strengthened. One other observation is of interest in relation to the expansion of technological education, and in particular to the need for fuller attention to training for management. In spite of all the efforts of the National Coal Board in training managers, it must be expected, writes Lord Simon, that another ten or twenty years will elapse before there will be an adequate supply of well-trained executives ready to take on jobs as members of the Board.

This long-term aspect of the selection and training of managers gives urgency to the expansion of technological education in Britain, and to its modification so as to ensure that both the colleges of technology and the universities provide industry and the public services with a constant supply of men and women imaginatively alive to human issues as well as to the scientific and technical aspects of the problems which will confront them—both civilized scientists and citizens understanding the essentials of science, as Sir Hugh Beaver puts it. Unless that supply is ensured and appropriate measures are taken now, both as regards numbers and quality, men of the desired quality may not be forthcoming in sufficient numbers even if, as Lord Simon suggests, the nationalized industries follow the methods adopted by the leading concerns in private enterprise in recruiting their boards. Like the Windscale accident, this analysis of the experience of the National Coal Board points to the need for vision, foresight and vigilance on the part of all concerned.

Lord Simon's survey of private enterprise is not limited to Imperial Chemical Industries, Ltd., though he gives greater details of that firm's board and of the National Coal Board. He points out very fairly that the boards of most good private enterprises to-day, especially some of the largest, are marked by a very deep sense of accountability not only to their shareholders but also to their employees, to their customers, and to the community. There is little reason for thinking that the general attitude of their board members either to efficiency or to public service differs from that of the board members of a nationalized concern.

Reviewing the boards of eight large private enterprises, Lord Simon notes the considerable number of graduates among their members, the substantial number of full-time directors, the care taken in the selection of new directors, and the background of long experience in the industry possessed by the majority of directors, in addition to the usual qualities that are looked for in an administrator and director of policy. The outstanding characteristic stressed by Lord Simon is their security of tenure. Changes in the boards are slow, and while this encourages confidence in the security of their jobs on the part of the directors, the consequent continuity is of the first importance in building up good traditions, wise policy and high efficiency.

---

* The Boards of Nationalized Industries. By Lord Simon of Wythenshawe. Pp. 54. (London: Longmans, Green and Co., Ltd., 1957.) 2*s*. 6*d*. net.

It is here that private industry is in most marked contrast with the nationalized industries. Whereas the director of a large private company is virtually sure of keeping his job until he reaches retiring age, the National Coal Board, for example, has been reconstituted twice since 1947. There have been twenty-four full-time members of the three Boards, although the number at any one time has never exceeded nine. The average length of service of those who have left has been 3·6 years, and no present member has yet served for three years; nevertheless, Lord Simon thinks that the present Board, whose members, on the average, have more experience of the industry than the average of the first two Boards, may be much more stable than its predecessors.

Lord Simon is convinced that security of tenure is by far the most important step towards continuity and efficiency of a board of directors, and it will be recalled that the Fleck Report on the National Coal Board also stressed the importance of continuity. Membership of the board of a nationalized industry should, he argues, be a career appointment; and although he agrees that the members should be appointed by the appropriate Minister, this should only be done after full consultation with the chairman and with the acceptance of the board. Further, candidates should have been selected and trained by the methods and on the scale of the best known practice, and appointments once made should continue up to retiring age, subject to the power of the Minister to terminate any appointment—a power which should rarely be used. Salaries, pensions and other conditions of service should be at least comparable with those in leading private firms; in this connexion the recent revision of salaries of members of various public boards, taken with the security of tenure stressed by Lord Simon, may help to overcome the present reluctance of outstanding men in a nationalized industry to accept appointments to its board.

This factor will obviously be of increasing importance when in ten to twenty years time the boards of the nationalized industries have an adequate supply of first-rate candidates from within the industry competing for vacant positions on them. Lord Simon's remarks on accountability also have a bearing in this connexion, though their chief interest is in a wider context. Having obtained a good board, an industry should be given the maximum freedom and responsibility subject to the necessary minimum of control by the Minister. This is essential if the board is to acquire the status that ultimately will enable it to recruit members of the calibre desired; and incidentally, as Lord Simon notes, to attract to the industry a sufficiency of the ablest graduates leaving the universities and colleges of technology of Great Britain.

The question of the exercise of Ministerial powers is regarded by Lord Simon as mainly a matter of good sense, but it should be a matter of high principle for every Government and every Minister to allow a board the maximum freedom and responsibility within the broad limits of national policy. On the strict issue of accountability, Lord Simon maintains that Parliament must realize that it is not competent to contribute anything whatever to the efficiency of, for example, the coal industry, while too much interference may cause serious inconvenience and even inefficiency. He agrees with Lord Heyworth that autonomy and responsibility to Parliament are inconsistent, and approves of Mr. Herbert Morrison's suggestion that accountability is best served by a periodical inquiry, at intervals of not less than seven years.

Lord Simon recognizes the value of parliamentary discussions in clarifying broad lines of public policy and indicating trends of public opinion, and also that the Parliamentary question, if it avoids matters of day-to-day management, is an important means of securing information and a safeguard against abuse. Here again it is largely a matter of common sense, and accountability may well become easier as the discussion of the problems of nationalized industries becomes more objective. That in itself should contribute to public confidence in the industries, as well as encourage greater stability and self-confidence within the industry and thus provide conditions in which the industry can develop its own standards and criteria of efficiency.

Here a suggestion made by Mr. R. Nottage, director of the Royal Institute of Public Administration, could be helpful. Discussing the use of the annual reports of the nationalized industries, he suggests that the adoption of a standard pattern might assist Parliamentary discussion. The record of operational results, both physical and financial, should facilitate adequate comparison with previous years and an understanding of the basis on which indices are selected. Presentation in such a form, with adequate reference to future plans and the periodical discussion of major topics on such a time scale as is adopted, for example, in the Unilever annual report, would give Parliament the information which the public interest rightly demands, and turn discussion into constructive channels rather than the detail and sterile issues which have been encouraged so much in the past. Lord Simon at least has indicated some of the opportunities. The juxtaposition of his pamphlet with reports of the Fleck Committees and of some other management literature should give a fresh impetus to measures for the expansion of scientific and technological education in Britain, upon the adequacy of which the quality of management and the efficiency of British industry ultimately depend. Education is, as always, the keystone of any such developments, and until a broad view is accepted of the scope of technical and technological education, the problem of supplying the men for the higher levels of management will remain with us.

ARCHITECT OF BRITISH MEDICAL RESEARCH

The Bright Countenance

A Personal Biography of Walter Morley Fletcher by Maisie Fletcher. Pp. 351+8 plates. (London: Hodder and Stoughton, Ltd., 1957.) 25*s*. net.

I HAVE heard it argued that it is a mistake for anyone to review the biography of a friend. He is biased from the start and likely to pay too much attention to the biographer's treatment of his friend, and too little to the literary or historical merit of the book itself. If this is so, then I should not be reviewing Sir Walter Fletcher's biography, for I am certainly biased from the start. Fifty years ago he was my tutor at Trinity College, Cambridge. He never attempted to preach at undergraduates or talk down to them. Instead he held up to us, quite unconsciously and in an almost diffident manner, a great example of poise, manliness and integrity of thought. Here was a man, we felt, firm of purpose and bound to the highest ideals of behaviour—a guide to be remembered in facing the moral and material issues of life which lay before us.

It was with these thoughts in mind that I opened this biography by his widow with some anxiety, for it is notoriously difficult for any woman to paint a true picture of her husband—difficult for her to interpret actions or even characteristics apart from their impact on her and apart from her own intimate association with them. I need not have feared. Lady Fletcher has succeeded in being objective. I am sorry, however, that, doubtless with this in view, she has written in the third person, thus removing not only herself but also the reader one stage from the scene. On the whole I should rather have read "I was delighted to see him back" than "Maisie was delighted to see him back". Another regret is that she has not used as her title Milton's words in full—"the bright countenance of truth". Not everyone is familiar with the quotation, and her publishers should not have allowed the abbreviation which makes the title so dreadfully misleading.

These, however, are small points. To me, at any rate, this book was a strangely moving revelation. His singleness of purpose, his amazing industry, his freedom from petty thoughts of all kinds, his joy in holidays and all out-door activities, his readiness to give always of his best whether in small things such as helping a troubled undergraduate or in great affairs of national medical policy—all these things we knew. What we now more fully realize is his courage, his deep spiritual convictions, and the real happiness he found in his family, his home and his friends.

To turn from the man to his work: this falls into two main periods—first, his years at Cambridge as research worker and tutor and Fellow of Trinity College, and then after 1914 his secretaryship of the Medical Research Committee (later Council) until his death in 1933.

His research work is summarized in Sir Arthur MacNalty's supplement to the book under review, but as full accounts are available elsewhere—notably in Prof. T. R. Elliott's obituary notice ("Obituary Notices of the Fellows of the Royal Society", 1, 153; 1933)—there is no need to refer to it in any detail here. It is sufficient to say that his studies, extending over some sixteen years, on the chemistry of muscular respiration were classical. As W. B. Hardy wrote, "origins are as difficult in science as in literature: here, however, it is safe to credit Fletcher with that first step that counts". He gave a new direction to biological thought.

From 1914 onwards Fletcher's life-work was to originate, inspire and support the research work of others. The National Insurance Act of 1911 provided that for each insured person one penny should be set aside for medical research. This, it was thought, would yield £57,000 per annum—an interesting comparison with to-day's annual expenditure of some £2½ million. The original proposal was to assign the whole sum to research on tuberculosis, a disease which was expected to be especially costly to the taxpayer. Wiser counsels prevailed, however, thanks principally to Dr. Christopher Addison (Viscount Addison), Lord Astor and Sir Robert Morant, and it was finally enacted that research could cover "any disease to which insured persons are liable". A Committee under Lord Moulton of Bank was appointed to administer the fund, with an advisory council of some forty medical men. But the appointment of a secretary was long postponed. As Gowland Hopkins wrote, "an ideal appointment seemed almost impossible of achievement. Looking back to those weeks during which it was in suspense, I feel that the future of medical research in this country was then facing a critical moment. But at last came the happy solution and it was T. R. Elliott who suggested it". Fletcher's appointment met with instant and general approval, particularly from Sir Robert Morant, chairman of the National Insurance Committee to which the Medical Research Committee was attached, who was a man inspired by almost fanatical zeal for benefiting the people of England in education, health and well-being. "These ideals," wrote a friend, "found not an echo but a counterpart in what had been innate in Fletcher, whose spiritual depths were uplifted by the vision of service for others in so wide a field. Scientific research became more than a beautiful use of the intellect in approaching the truths of Nature, for he now realized the need by England of its direct application to all the problems of ill-health. Henceforward he, too, became a great public servant and sank his own conspicuous abilities for research in guiding and helping countless other men."

From the first the Committee's policy was to set up a comparatively small central research institute with its own staff, and to spend the greater part of the funds in support of investigations in private or voluntary institutions, where hitherto nearly all medical research had been done with little if any help from the State. The Mount Vernon Hospital at Hampstead was purchased and four Departments set up in temporary accommodation—(1) Bacteriology (Sir Almroth Wright and S. R. Douglas), (2) Biochemistry and Pharmacology (H. H. Dale), (3) Applied Physiology (Leonard Hill and Martin Flack), and (4) Statistics (J. Brownlee). A proposal to include a research hospital of twenty beds was abandoned on Fletcher's advice: he rightly considered that clinical research could better be carried out at existing and fully equipped hospitals.

The outbreak of the First World War interfered with many other plans, but Fletcher at once saw that military needs gave him an opportunity for establishing beyond all doubt the importance of medical research and the vital service which it could render.

He submitted a White Paper (Cd. 7922) containing proposals for research in direct connexion with the war and, most important of all, established full collaboration with the Army Medical Department. With the active help of Sir Alfred Keogh, Director General of the R.A.M.C., a channel for information and research on specific problems was operative between the Medical Research Committee and the army medical services in the field and home hospitals throughout the war.

With the return of peace and the establishment in 1919 of the new Ministry of Health came another moment of crisis in the history of the Medical Research Committee, for it was proposed to place it under the control of the new Ministry. Fortunately Fletcher had two enlightened men to deal with—Addison and Morant. Fletcher argued, first, that a progressive Ministry of Health will inevitably find itself committed from time to time to particular policies of health administration. A research organization under its control would be obliged to keep in step with current policy, instead of being free to recommend changes in policy in the light of new knowledge. Secondly, if the research organization formed part of the Ministry, its activities might come to be unduly restricted to problems of pressing practical urgency relating to the Ministry's executive functions, thereby excluding fundamental work which in the long run might be of more value. Thirdly, the Ministry operated only in England and Wales, but research organizations should cover the United Kingdom and reach out to the whole Commonwealth and Empire.

These views were accepted and in 1920 the Medical Research Committee became by Royal Charter the Medical Research Council, reporting to the Privy Council (an arrangement already in force with the Department of Scientific and Industrial Research and to be repeated in 1931 with the Agricultural Research Council). Only the other day a senior official of the Ministry of Health commented on this decision. "I am devoted", he said, "to the Ministry I have served so long. I believe it has done and is doing good work. But the greatest of the services which Fletcher rendered to medicine was to prevent the Medical Research Council from becoming its servant."

The subsequent progress and achievements of the Council need no recapitulation here. As Sir Arthur MacNalty writes, "it is not given to every pioneer to see the results of his labours, but Fletcher had the supreme satisfaction of knowing that the cause to which he had devoted all his energy and gifts had triumphed, and that he had established medical research in this country on secure foundations".

Lady Fletcher has written this biography primarily, she says, for "Walter's nine grandchildren", but she has placed all who knew him in her debt. Two comments which she quotes together sum up, I think, what we realize still more clearly after reading her book. The first is from *The Times* leader on the day after his death: "Fletcher was friend to every honest seeker after truth and he possessed in special degree the faculty for friendship. . . . His loyalty was unquenchable and he served no ends except those of the good of his fellows". The other is from his cousin, Sir Clement Jones: "Ever since my first year at Trinity I remember Walter as one who excelled in everything he tried to do, and he always aimed at the very best things and the high and honourable things. I shall never hear his name mentioned without thinking of those high standards in work, in play, in conversation and perhaps above all in friendship". May I, in conclusion, add one more quotation, from a letter by Sir Ernest Gowers, because it so exactly reflects my own feelings: "I never ceased to feel his friendship was an honour as well as a delight". WILLIAM GAVIN

IRRIGATION WORKS

Irrigation and Hydraulic Design

By Dr. Serge Leliavsky. Vol. 2: Irrigation Works. Pp. xvi+864+85 plates. (London: Chapman and Hall, Ltd., 1957.) 294*s* net.

THIS, the second volume of Dr. Leliavsky's monumental trilogy on irrigation, is devoted to the specific design of irrigation works. The first volume, comprising Chapters 1–3, contained the theoretical background necessary for the hydraulic side of the design, while this volume, comprising Chapter 4–8, is concerned with the detail of the structures and irrigation planning. As in the first volume, the approach is basically historical, a treatment which has both advantages and disadvantages. The main advantage for the reader is that of having the steady progress of the subject explained and commented on by one who was himself in daily contact with, and in the forefront of, these developments. The disadvantage is that as a design manual, which is the intention of the book, the treatment in places becomes discursive and prolix.

The scope of the book is sufficiently well illustrated by the chapter headings, which are: the design of regulators (Chapter 4); the design of irrigation and drainage syphons (that is, cross-drainage works) (Chapter 5); weirs and other hydraulic works (Chapter 6); planning and designing a perennial irrigation scheme (Chapter 7); and canal bridges, aqueducts and gates (Chapter 8). The engineer will particularly welcome the detailed analyses of examples of various types of structure drawn from existing works mainly within the author's own experience. Study of these should enable a competent engineer to design similar structures for himself. The last chapter comprises more than a third of the book, and is devoted exclusively to structural design. In the case of gates, the author is here concerned with the static loading, although vibration normally plays a major part in failure, as it did in the one case quoted by him. In general, problems of chatter and fatigue failure loom large in high head structures, and designers would welcome more guidance on these matters.

The general system of irrigation used as a model in the book is naturally, in view of the author's close association with it, that practised in Egypt. It is clear that the main problem now facing engineers in that country is waterlogging, due to the too liberal application by cultivators who had for many years been starved of water. However, the problem of soil salinity now menacing the irrigation communities in India does not seem to have appeared in Egypt. A comparison of the two systems might reveal why this is so, and it might well be that the installation of a system of drains and pumping stations rendered necessary to deal with waterlogging in Egypt might also have to be faced in India for the quite different purpose of leaching out salts.

The second major difficulty of irrigation, namely, siltation and the problem of designing canals which neither silt nor scour, has received a somewhat superficial treatment, the author contenting himself with quoting a number of design formulæ and graphs without probing the matter more deeply. The reasons for the different formulæ used in Egypt and India are not stated and no guidance is given as to the particular form to be adopted in other areas. The most recent formula for the velocity–depth relation for non-silting canals has quite a different form from that previously adopted, although a thorough analysis is precluded by lack of data concerning the size and amount of solids carried by the canal.

The layout of the book is excellent and the text, which is both lucid and fluid, is illustrated by a large number of diagrams and plates. However, design offices will regret the frequent changes of units.

G. H. Lean

DISEASES OF CEREAL CROPS

Cereal Diseases in Ireland

By Prof. Robert McKay. Pp. x+161+54 plates. (Dublin: At the Sign of the Three Candles, 1957.) 21*s*.

THIS is the sixth in the series of handbooks dealing with crop diseases in Ireland written by Prof. R. McKay, illustrated with splendid photographs by G. H. McLean and published by the Three Candles Press. Of similar format to its predecessors, this volume deals with the diseases of cereal crops; it has an excellent frontispiece in colour with occasional colour plates scattered through the text. The foreword is by the Earl of Iveagh. The book is divided into six sections with an appendix. The sections deal respectively with the rusts, smuts, other parasitic diseases, parasitic diseases occasionally seen, miscellaneous diseases of non-parasitic origin and eelworm attack, while the appendix gives some account of the barberry and buckthorn, alternate hosts of some of the most important cereal rusts, with special reference to their distribution in Ireland. It could be suggested that the material dealt with in the appendix would have been better placed with the section dealing with the rusts.

Some passages, such as appear, for example, in the section dealing with loose smut of oats, read a little more like a text-book of plant pathology than a semi-popular treatise, but this merely illustrates the great difficulty the author of such a work as this has in consistently envisaging the needs of the readers for whom the book is intended. It is no easy matter to prepare a glossary of terms for a work such as this and, although a useful one is provided, the omission of some such as ascocarp, stroma, mesocotyl, etc., is noticeable. The illustrations of disease symptoms are profuse and excellent, but when so much mention is made in the text of the various spore forms of the rust fungi, for example, it seems a pity that some attempt was not made to illustrate these and their methods of germination. The choice of references would have been improved by being more inclusive.

The book is written in a simple straightforward style and is very readable. Part of the reason for its appearance is as a guide to agricultural advisers to help them to be able to identify, more readily, cereal diseases in the field. It is also intended to be of service to young farmers attending winter classes in agriculture or engaged in club work. The book is excellently produced and maintains the high standard of the Three Candles Press. There are very few errors, printing or otherwise, and only two were detected. The illustrations are particularly valuable and up to the high standard one might expect. Priced at one guinea, the publication is worth the money as a book, although it may seem a little expensive for many for whom it is intended. The whole tenor and tone of the work, like that of the earlier volumes, denote the enthusiasm of the author and mark him out as one of the keenest plantsmen that Ireland has produced.

A. E. Muskett

GUIDES TO ORGANIC CHEMISTRY

Organic Synthesis

By Dr. Vartkes Migrdichian. Vol. 1: Open-Chain Saturated Compounds. Pp. xxviii+834. Vol. 2: Open-Chain Unsaturated Compounds; Alicyclic Compounds; Aromatic Compounds. Pp. xiv+835–1822. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1957.) £14 the set of two volumes.

SINCE the inception of the fundamental theory of organic molecular structure a century ago (1858), with the addition seven years later of that "crowning achievement of the doctrine of the linking of carbon atoms", the idea of the benzene ring, organic chemistry has advanced in a kind of geometrical progression. A concrete expression of its vast scope at the present day is embodied in the current edition of "Beilsteins Handbuch", which includes to date some ninety massive volumes, although (except for the latest volume) these cover the literature only to 1929. It is understandable, therefore, that the specialist in organic chemistry is nowadays largely dependent upon various types of more concise and up-to-date guides to this great efflorescence of organic chemical information. Such guidance is afforded by a multiplicity of monographs on special fields and by various periodicals exemplified by the American publication, "Chemical Reviews", and the British "Annual Reports", *Quarterly Reviews* and *Current Chemical Papers*.

A fundamental problem lies in the effective presentation of the large number of chemical reactions now available for preparative and research work, in both pure and applied organic chemistry. Very helpful in this way are the American publications, "Organic Syntheses", an annual collection of reliable preparative methods for individual compounds, and "Organic Reactions": each of the nine volumes of the latter, issued since 1942, deals in detail with a number of reactions of synthetical importance.

Dr. Vartkes Migrdichian's work, although bearing upon the same ultimate problem as these two publications, differs from them in two important respects. First, it is not a periodical but a complete work; secondly, his review of reactions is comprehensive and systematic, instead of being limited to an arbitrary selection and arrangement. The first volume covers the open-chain saturated compounds; the second takes in the much wider field of open-chain unsaturated compounds, alicyclic compounds, and aromatic compounds. A third volume dealing with heterocyclic compounds is contemplated.

The thirty chapters follow closely the arrangement of a standard text-book of organic chemistry. Methods of formation are followed by a review of reactions of the type of compound under discussion. The Grignard and Friedel–Crafts reactions, and the diene synthesis, with their exceptionally wide applications, are treated separately. In general, however, reactions are classified under the heading of compounds of the type with which they are chiefly associated: thus, the Fries reaction will be found under the heading of phenol esters; and the Wagner, Nametkin and Demjanow rearrangements under alicyclic hydrocarbons.

The work is a useful compendium of an enormous amount of material, and is fully documented, although the literature of the past decade is sometimes sparsely represented. Theoretical discussions are not included, and reaction mechanisms are mentioned only when generally accepted. The text, formulæ and tables are clearly printed by a modern economic process; nevertheless, the price is distinctly high. As might be expected, in so extensive a compilation, misprints are not uncommon.

Dr. Migrdichian, who is senior research chemist to the American Cyanamid Co., with a record of some thirty years in the field of work leading to these volumes, is to be congratulated upon the result of prolonged labours that will minimize those of the many organic chemists who will derive welcome help from this publication. John Read

ELECTRICITY AND ELECTRICAL MACHINES

Electrical Engineering (General)

Electrical Circuits—Instruments and Measurements—Electric and Magnetic Fields—Conductors—Insulating and Magnetic Materials—Electronic Tubes. By A. T. Dover, Dr. F. T. Chapman, Prof. F. Brailsford and Harley Carter. (Electrical Engineering Series.) Pp. ix+489. (London and New York: Longmans, Green and Co., Ltd., 1956.) 50*s.* net.

Electrical Machines

By A. Draper. (Electrical Engineering Series.) Pp. xvi+346. (London and New York: Longmans, Green and Co., Ltd., 1956.) 40*s.* net.

The General Theory of Electrical Machines

By Bernard Adkins. Pp. ix+236. (London: Chapman and Hall, Ltd., 1957.) 45*s.* net.

THE first two books belong to a series intended for use by students preparing for Higher National Certificate, degree, and other examinations. The preface states that "Electrical Engineering (General)", the first of the series, is limited in scope to theory connected with electric circuits, instruments and materials for use with direct currents and alternating currents of power frequencies. The manner and depth of treatment vary considerably from topic to topic. Three chapters contributed by Prof. Brailsford provide a lucid and up-to-date account of ferromagnetic phenomena. Unfortunately, the same fundamental approach has not been applied to the discussion of conducting and insulating materials, the treatment of which is reminiscent of an engineer's handbook. This criticism could also be levelled at some of the material concerning commercial measuring instruments. It is perhaps inevitable that a book written by a panel of authors should consist of discrete sections, but it must be confusing to students to find, for example, a discussion of network theorems as part of direct-current circuit theory, without any mention of their general application, while later the star-delta equivalent impedances of a 3-phase circuit are derived without any reference to an earlier and similar derivation among the network theorems. Despite the declared limitation to power frequencies, two chapters on electronics describe various types of radio-frequency apparatus. A useful and comprehensive selection of examples, with answers, many taken from examination papers, is provided at the end of the book.

" 'Electrical Machines' has been written as a text-book for students and not as a treatise for designers." Here, at last, students can find under one cover details of nearly all types of electrical machines. The omission of the single-phase machine is, however, to be regretted; it is, after all, very common. Academically there also appears to be no justification for including the mercury-arc rectifier in a book on machines. The approach to the subject is logical and on traditional lines, and should appeal to the student of electronics studying machines as a secondary subject. He will also find the sections on rotating and magnetic amplifiers very useful. The book can be recommended unconditionally to such students. Those taking heavy-current subjects for a degree course will probably wish for greater depth of treatment, but it is an excellent second-year book. The author and the British Thomson-Houston Co., Ltd., are to be highly commended for the clarity of the diagrams, so essential to a book on machines. The examples at the end of the book are well chosen, even though there is a mixture of units. The appendix on the measurement of three-phase power will prove very useful to students in the laboratory.

The general theory of electrical machines has been presented by several writers in a form so mathematical as to appear remote from whirling masses of copper and iron, and the publication of Mr. Adkins's book, in which the theory is applied to computing the details of machine performance under varying conditions, is all the more welcome. The author is a reader in the University of London, and his careful explanation of small detail shows his appreciation of the needs of students; but he has behind him an industrial career much longer and more distinguished than most professors or lecturers. This greatly enhances the value of his work, for he speaks with authority on the relative numerical importance of the terms in his equations, and is thereby enabled, by eliminating small effects, to present a clearer picture of the chief phenomena. His use of the 'per-unit' system is perhaps open to criticism in a students' book; it is easy to see its value to the designer, but it takes the student too far from fundamentals, destroys the dimensional consistency of the equations, and involves the author in quite a number of interpolated explanations of the values of coefficients. It is also possible to regret the somewhat disproportionate space accorded to the synchronous machine as compared with other types of a.c. motor. Nevertheless, the book is the best yet written in English to develop machine performance from general principles in a manner calculated to appeal to engineers and engineering students.

Science and Existence

Two Ways of Knowing. By Alan Richardson. (Technics and Purpose, No. 1.) Pp. 30.

Scientific and Technological Education

By Edwin Barker. (Technics and Purpose, No. 2.) Pp. 37.

Technical Education

By H. A. Warren. (Technics and Purpose, No. 3.) Pp. 37.

Purpose in Teacher Training

By Monica Wingate. (Technics and Purpose, No. 4.) Pp. 38.

(London: S.C.M. Press, Ltd., 1957.) Each 2*s*. 6*d*. net.

THE British Council of Churches is sponsoring a series of booklets to examine the issues arising out of the growth of science in society and the rapid expansion of technological education, particularly in relation to the purposes and values involved in the light of the Christian faith. For several years a working party convened by the Education Department of the British Council of Churches, under the chairmanship of Sir John Wolfenden, vice-chancellor of the University of Reading, has been meeting to consider some of the issues involved; it has now asked certain individuals to take responsibility for bringing together some of the views expressed in discussion. In the first booklet Prof. Alan Richardson, of the University of Nottingham, distinguishes with great clarity between 'scientific' and 'existential' knowledge. The narrowness of scientific and technological education is examined by Edwin Barker, assistant general secretary of the National Council of the Young Men's Christian Association, in the second booklet, while in the third, H. A. Warren, principal of the South-East London Technical College, describes the system and scope of technical education in England and Wales and makes an appraisal of some of its social and cultural effects. In the fourth booklet, Monica Wingate, principal of Balls Park Training College, searches out the purpose in teacher-training with irresistible persuasiveness; her readers might have been even more sympathetic if she had first made sure that they were aware of the ways in which teachers are trained in Britain's training colleges. Before other booklets in this series are produced, more thought might be given to the purpose behind each and to make this clear in a preface; the sequence in which they are issued should also be examined.

T. H. Hawkins

Malayan Orchid Hybrids

By M. R. Henderson and G. H. Addison. Pp. iv+191. (Singapore: Government Printer, 1956.) 21 Malayan dollars.

ALTHOUGH there is such a wealth of orchid hybrids available for cultivation in temperate countries, many of these are not happy when grown under tropical conditions. Successful efforts have therefore been made in recent years to develop hybrids within other orchid genera which are better suited to the tropics. These include the genus *Dendrobium* (particularly the section *Ceratobium*), the climbing orchids of the Vanda-Arachnis group, the strap-leaved *Vanda* species and *Spathoglottis*. The chief two centres in which this hybridization has been carried out are Malaya and the Hawaiian Islands. The present book aims at providing photographic illustrations of the more important and beautiful hybrids which have been raised, or are commonly cultivated, in Singapore.

For most varieties dealt with there are photographs of a single flower and of a complete inflorescence. These photographs reach a high standard and are excellently reproduced on art paper. Accompanying them are brief texts which include information about parentage and place of origin as well as short descriptions and notes on cultivation. Well-illustrated and concise accounts of the cultivation in Singapore of the main groups of hybrids precede each section of the book.

Orchid growers in Malaya and in the neighbouring countries will welcome this book and it will be of value to growers in other tropical regions. It will also serve to stabilize the nomenclature of these hybrids, to which additions are continually being made. Altogether the authors are to be congratulated on the production of a useful as well as very attractive book.

A Glossary of Mycology

By Walter H. Snell and Esther A. Dick. Pp. xxxi+171 (15 plates). (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1957.) 40*s*. net.

MYCOLOGY, like all other sciences, has developed its own shorthand terms to describe the diversity of form, substance and function of fungal organisms. The present volume describes nearly seven thousand such terms, and, apart from the names of colours and certain words used in general botany, most have no meaning outside this science. This number of words is almost enough, in a simpler context, to found a language; have we too many of them? The majority save quite lengthy explanations, and so are justified as shorthand. A considerable number apply only in special parts of mycology, but this serves to indicate fungal complexity rather than redundant verbiage. A few terms, now obsolete but used in earlier literature, have historical value. A minute minority are colloquial. Colour names link those in the authoritative but relatively inaccessible "Repertoire de Couleurs" with other and more available specifications. Fifteen very clear line blocks by Henry A. C. Jackson elucidate many terms. The authors have, in all, performed a most necessary service, and have done it in a most scholarly manner.

J. Grainger

The Life of the Shrew

By Dr. Peter Crowcroft. Pp. vi+166. (London: Max Reinhardt, Ltd., 1957.) 15*s*. net.

THIS is an excellent account of the biology of the species of British shrews, with perhaps more emphasis on the common and pigmy shrews. Their general behaviour, fighting propensities, reproduction, activity rhythm and feeding, their longevity (or should it be brevity?) and their position both as predators and prey are all dealt with. Much is the result of the author's own observations and experiments; but all the previously known facts have been incorporated in a very readable book. The shrew's reputation in folk-lore and in naturalists' accounts, even as late as 1911, is shown to be largely erroneous. The gaps in our knowledge and the methods by which they may be filled are dealt with in a stimulating and attractive manner. There are a good bibliography and index, while the tailpieces by Erik Thorn portray the characteristic postures and behaviour of shrews most admirably.

H. R. Hewer

ALPHA-RAY ACTIVITIES OF HUMANS AND THEIR ENVIRONMENT

By R. C. TURNER, J. M. RADLEY and Prof. W. V. MAYNEORD
Physics Department, Institute of Cancer Research: Royal Cancer Hospital, London, S.W.3

THE radioactivity of the human body and its environment has become a matter of increasing importance and concern particularly in view of the hazards now known to be associated with the ingestion or inhalation of small quantities of radioactivity. It is well known that the human body normally contains small quantities of naturally occurring radioactive elements particularly concentrated in bone[1-3]; but to what extent these materials are derived from foodstuffs, drinking waters, or other ingested substances, is largely unknown for a particular individual. The knowledge of the natural radioactivity of our environment is so scanty that it seemed possible that a number of natural sources of irradiation of human beings exist of which we are, at the moment, ignorant. Although largely unknown, these levels of radioactivity have been assumed to be of rather academic importance, yet they form the only sure ground upon which we may argue as to the dangers of different levels. For example, the natural background of γ-rays gives us a standard by which we may judge the possible effects of increased radiation on the genetic material of the race, while the natural radiation to which bone for many generations has been exposed gives us a basis on which to judge any possible increase in the production of bone tumours or leukæmia. Since many of the naturally occurring radioactive nuclides emit α-particles it seemed worth while to look again for such α-activities both within the human body and its environment. This article outlines the results of investigations over a fairly wide range on many hundreds of samples.

Experimental Technique

We have devised a simple method which enables us to measure α-activities without elaborate chemical preparation[4].

The material, the activity of which is to be measured, is often human or animal tissue and is normally prepared by ashing at 600–700° C., and grinding the residue to a powder. A shallow translucent tray is formed by stretching Scotch tape over one surface of a 'Perspex' ring about 11 cm. internal diameter and about 3 mm. thick. The inside adhesive surface of the tray so formed is covered with a thin layer of finely powdered nickel-killed zinc cadmium sulphide which serves as the α-detecting phosphor. The tray is filled with the powdered sample and is sealed by further layers of Scotch tape stretched across its upper surface. Such a tray holds 2–3 gm. of unit density material of which only about 150 mgm. contribute to the counting, the precise amount depending, of course, upon the range and therefore the nuclide from which the α-particles come. This sealed tray ensures freedom from contamination. Samples may be stored indefinitely, and repeated measurements made at appropriate intervals, the rate of rise of activity to equilibrium after sealing yielding important data in identification of nuclides present. The sealed sample is presented to the photo-cathode of a multiplier and the α-particles counted by suitable techniques. The lowest backgrounds observed by us were obtained using samples of aged distilled water, and are approximately 3 counts per hour in counting periods extending over a week. The sensitivity of the method may be gauged from the fact that 1 count per hour above the background corresponds to about 4×10^{-14} c./gm. of sample and thus enables the normal α-activity in bone ash (that is to say, about 2×10^{-13} c./gm.) to be determined to an accuracy of some 15 per cent in a counting time of 24 hr. Details of the technique will be published elsewhere[4]; but it is obvious that great care has to be taken to avoid contamination. The method has been modified to measure the activities of solid, liquid or gaseous samples. A study of the elementary geometry of counting shows that the number of particles (N) emitted per unit volume per unit time and the range (R) of the particles in the material are the determining constants, and that the product $NR/4$ gives the number of particles per cm.^{2} which are observed in a given time. We have discussed in detail[4] the effects of density and of atomic number on the range of the particles and calculated mean ranges in media of varying atomic numbers and densities.

Early in the experiments it was observed that materials containing thorium and its daughters, at low counting rates of the order of 10–100 counts per hour, yielded a number of closely spaced pairs of α-particles. These arise from the two consecutive α-transitions thoron (220) to thorium A (216), and thence to thorium B (212). Since the half-life of thorium A (216) is only 0·14 sec., and since no analogous phenomenon occurs in the radium series, the frequency of occurrence of these fast pairs gives a direct measure of the rate of disintegration of thoron atoms. The results must, of course, be corrected for the chance occurrence of spurious pairs. By a development of this argument it is possible to estimate what fraction of the observed total α-count arises from the uranium and from the thorium series respectively. This phenomenon, well known in the history of radioactivity[5], has enabled us to demonstrate and measure the fraction of the activity of normal human bone which arises from the thorium series.

Abnormal Radioactive Contents in Humans

Some of our first experiments were carried out on samples of the humerus from a radium worker who ingested active material around the period 1910. The observed counting rates were very high, 17,500 counts per hour in our normal sample, and the resulting activity of $4{\cdot}70 \times 10^{-11}$ gm. radium-226 per gm. wet bone was in good agreement with estimations of radium which had previously been made by pressure ionization chamber techniques, autoradiography, physical-chemical assays and excreted radon[6]. We have also measured a number of samples of humerus from a worker who ingested both radium and mesothorium 8–10 years earlier. Again, the estimated ratio of radiothorium to radium was in good agreement with previous measurements, as were the absolute values of $5 \cdot 3 \times 10^{-12}$ c. and $5 \cdot 9 \times 10^{-12}$ c./gm. wet bone respectively (Spiers, F. W., private communication). It was established that other bones of the same subject (ribs and sternum) gave values for the radiothorium ranging from $6 \cdot 0 \times 10^{-13}$ c. to $5 \cdot 3 \times 10^{-12}$ c. per gram of wet bone, but the ratio of radiothorium to radium (0·89) was surprisingly constant throughout the various parts of the skeleton.

As a further example of the flexibility of the technique we may mention that we have measured the breath and the blood of a patient who was given 'Thorotrast' for diagnostic reasons some twenty years ago. The estimated breath activity was $1 \cdot 5 \times 10^{-9}$ c. thoron per litre and the blood content of thorium $B = 3 \cdot 5 \times 10^{-12}$ c./cm.^{3}.

Normal Radioactivity in Humans

The cases we have quoted are of patients having very large radioactive burdens perhaps ten thousand times greater than those of the general population, and we now turn to studies designed to find the mean level of α-activity of normal populations. We were particularly anxious to obtain data concerning young children since little information exists as to the concentrations of radioactive material present at birth. We have, therefore, made measurements on as much stillborn material as could be obtained.

Observations have been made on the α-activities of bones of persons native to Cornwall, London and Cumberland, respectively. 31 Cornish (humerus), 17 Cumberland (femur) and 12 London (humerus) bone specimens have been examined. In the case of the 11 stillborn children, all of whom were full-term, low calcification and small size of the bones make it necessary to ash the whole of one of the long bones, in this case the femur.

The results of the human bone measurements are shown in Fig. 1. It will be observed that there is great variation in absolute level, and that on the whole Cornish bones have higher values than those observed from the London area or from Cumberland. The mean content of the Cornish material was $5 \cdot 0 \times 10^{-13}$ c. of α-activity per gm. bone ash compared with $1 \cdot 7 \times 10^{-13}$ c. for the London area. This difference appears to be statistically significant; but the question remains as to whether the subjects form representative samples of the inhabitants of the two regions. The values could be influenced by geographical factors, and also by the fact that a number of the specimens drawn from the London area were cases of advanced malignant disease known to have low calcium content. It will be shown later that differences in feeding habits could also be very significant. One of the most interesting findings is the unexpectedly high value for the concentration of α-activity of stillborn children[7], the mean value in our experiments being $4 \cdot 5 \times 10^{-13}$ c. per gm. bone ash. It appears that in adult bone approximately 40 per cent of the α-activity is due to the radiothorium series. For the 11 stillborn children the mean fraction is the same, a result which is particularly interesting.

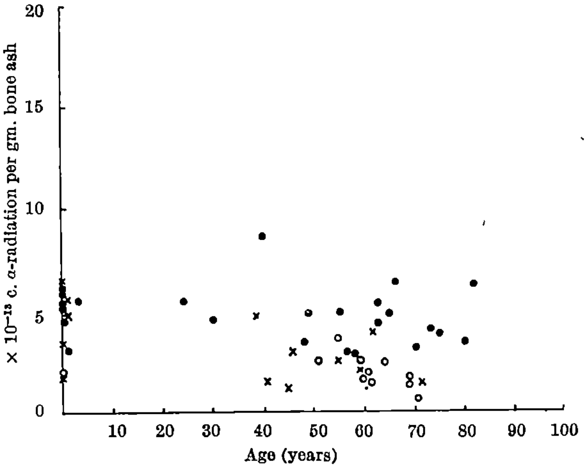

Fig. 1. Human bone ash, total α-activity. ●, Cornwall; ×, London; O, Cumberland

The other striking feature of Fig. 1 is that there is no obvious correlation of α-activity with age. In view of the great interest in the radioactivity of children we have measured four samples of liquid milk and found a mean value of $3 \cdot 1 \times 10^{-13}$ c. per gm. ash. This implies that the total α-content and the mean radium content of a pint of milk from the London area are, respectively, 1·3 μμc. per pint and 0·22 μμc. of radium per pint. In a few months the total intake of the human infant, if completely incorporated into the body, would be sufficient to provide most of the radium found stored in the adult. Later experiments suggest, however, that a large fraction may be excreted.

We have also measured the total α-content of two samples of human mothers' milk ash, and obtained values of $7 \cdot 9 \times 10^{-13}$ and $3 \cdot 1 \times 10^{-13}$ c. of total α-activity per gm. ash. The activity appears to be divided about evenly between radium and radiothorium.

Radioactivity in Animals

It seemed natural in view of these activities in milk to study the radioactivity of cows. Measurements of samples of long bones of 18 cows yielded values of total α-activity ranging from $2 \cdot 0 \times 10^{-12}$ c./gm. ash to $6 \cdot 0 \times 10^{-12}$ c./gm. ash with a mean of $3 \cdot 0 \times 10^{-12}$ c./gm. ash. It will be seen that the mean total α-activity per gm. of ash for cows is about ten times that of the humans. One very high activity in a 'marrow bone' ($1 \cdot 0 \times 10^{-11}$ c. per gm. ash) is interesting, as also is the observation that the radioactivity in the bone of cows consists of about equal parts of radium and thorium series. By ashing the bone marrow of cows separately we found that the activity of the bone marrow is the same as the activity of the bone (c. per gm. ash) but relatively rich (2 : 1) in radiothorium compared with radium. In further experiments we have measured the activities of cow spleens and found a mean value of $1 \cdot 8 \times 10^{-12}$ c./gm. spleen ash, again, with about equal parts of the thorium and radium series. The ratio of α-activity in milk to the activity appearing in bone is very different in humans and cows, the ratio being at least ten times higher for humans. These observations suggest interesting comparative physiology of different species.

It may be of interest to mention that we have also made preliminary observations on some other

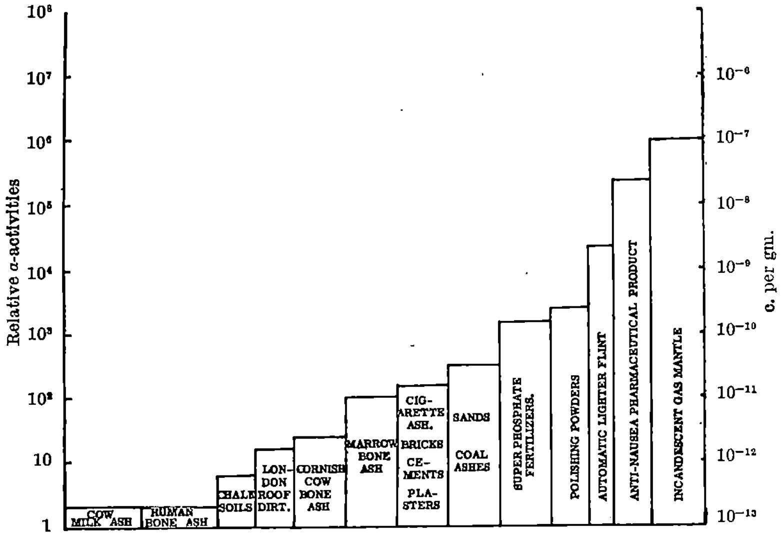

Fig. 2

species, as, for example, bones of five sheep which show values between 2 and 6 × 10^{-12} c. per gm. ash. Observations on the bones of pig reveal very low activity, while the bones of a horse, 18 years of age, are also quite low at 3·8 × 10^{-13} c. per gm. ash. It is evident there are differences between the natural radioactive content of bones of various species, but we are at the moment ignorant as to whether or not these are real species differences or determined by feeding habits.

Soils

We have also made observations on forty types of soils and fertilizers. They were not necessarily representative, but grab samples taken in various ways. We have found that chalk is low in activity (7 to 8 × 10^{-13} c. of α-activity per gm.), a fact of great importance to us in the design of new low background laboratories. The next lowest soils are the limestones, as is indeed well known[8]. One of the most active materials we have encountered is fossil superphosphate (1 to 2 × 10^{-11} c. α-activity per gm.), but again these activities were well known and may be so high that in the United States, for example, the extraction of uranium from superphosphate residues is worthwhile commercially[9]. The high values for superphosphates may have a bearing upon the observed activities of cattle bones.

Various Environmental Materials

In another series of experiments α-activities have been found in a number of substances in which thorium and rare earths are closely associated. It is not uncommon for thorium to pass through the chemical separation processes in company with materials like cerium, thus giving rise to the activities we have observed. Among the materials examined, conspicuous ones are lighter flints (3 × 10^{-9} c. α-activity per gm.), cleaning materials of various kinds involving cerium (4 × 10^{-10} c. α-activity per gm.) and in one instance a pharmaceutical product which evidently contains a large percentage of thorium (Fig. 2).

Human Metabolic Experiments

In view of the extremely wide range of naturally occurring activities in the human environment it seemed of great importance to discover the immediate sources of radioactivity of the normal human. We have, therefore, carried out a 'balance' experiment on a normal young human subject with the view of investigating the magnitude of the intake and excretion of naturally occurring radioactive material.

Samples of every food eaten by a boy (4 years old) over a period of a month were assayed for α-activity,

Table 1

Foodstuff	Maximum α-activity observed per 100 gm. × 10^{-12} c.
Cereals (breakfast)	60
Liver and kidney	15
Flours	14
Chocolates	8
Biscuits	2
Milks (evaporated)	1–2
Fish	1–2
Vegetables	0·7
Meat	0·5
Fruit (tinned)	0·5

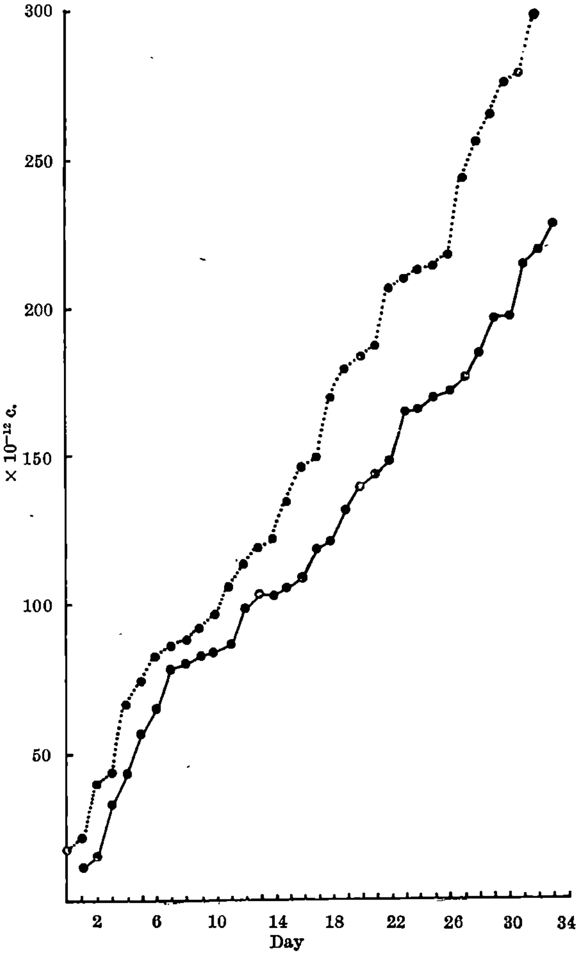

Fig. 3. ●···●, Intake, total α-activity, 299·2 × 10^{-12} c.; ●—●, fæcal excretion, total α-activity, 228·8 × 10^{-12} c.

as was each daily fæcal sample excreted during that time. It was immediately found that not only were the fæcal samples easily measurable but also examination of a number of foodstuffs revealed variations in α-activity ranging over factors of 4–5 hundred times (Table 1 contains a small selection of those found relatively active). The intake over a period of a month was $3 \cdot 0 \times 10^{-10}$ c. of α-activity with the fæcal excretion 20 per cent lower. Fig. 3 shows the integrated daily intakes and fæcal excretions.

The main conclusions from this pilot experiment are:

(*a*) Food is, in this instance, the important factor determining the daily intake of naturally occurring radioactive material, and its contribution completely overshadows the intake from milk and water, hitherto often supposed the main sources.

(*b*) The levels of α-activity in foodstuffs are extremely variable but, in general, high values are obtained for cereals and flours, particularly those in which whole wheat is utilized.

(*c*) The intake per day from food, even for a child of 4 years of age, may approximate the whole body burden. For an adult, the intake can exceed 10^{-10} c. of α-activity per day.

(*d*) The ratios of radiothorium to radium in the intake and in the fæcal excretion are substantially the same (0·75). This ratio is higher than that found in the human bone studies (0·6) possibly because of the relatively higher values of radiothorium in such organs as the liver and spleen.

(*e*) The daily retention of radiothorium and radium is evidently a small fraction of the intake but cannot be estimated accurately by our simple 'balance' study. Excretion in urine is approximately 10 per cent of fæcal excretion, leaving an estimated 10 per cent real absorption.

(*f*) The mechanisms controlling the retention by the body are evidently of great importance in estimating possible biological effects due to the radioactivity presented to it, since the bulk of the daily intake of radium and thorium series is excreted during the next 48 hr. This is demonstrated by the high values of fæcal activity on days following the ingestion of particularly active foods.

(*g*) It is clear from the values found in foodstuffs that two persons on apparently normal diets may differ in total daily radioactive intake by factors of hundreds. This makes the variations of α-activity observed in the human skeletal studies scarcely surprising.

We are continuing these physiological studies with the view of a better understanding of the metabolism and resulting dosimetry due to natural and artificial radioactive substances.

FORMATION OF TWO- AND THREE-STRANDED HELICAL MOLECULES BY POLYINOSINIC ACID AND POLYADENYLIC ACID

By Dr. ALEXANDER RICH
Section on Physical Chemistry, National Institute of Mental Health, Bethesda, Maryland

A GREAT deal of interest has been aroused by problems associated with the structure and function of ribonucleic acid. This substance is found widely distributed in various parts of the cell. Although some of it is in the nucleus, where it is near the deoxyribonucleic acid, most of the ribonucleic acid is in the cytoplasm, where it is either closely associated with protein to form the particles in the microsomal fraction or is free in the supernatant. Because it constitutes almost half the microsomal particles in which protein synthesis is carried out[1], it is widely believed that it takes a fundamental role in this process, such as helping to determine the sequence of amino-acids in the newly synthesized protein. It has also been demonstrated that ribonucleic acid can function as a carrier of genetic information. If ribonucleic acid is isolated from the tobacco mosaic virus, it is capable of infecting the tobacco leaf and thereby producing a large number of new virus particles which carry the genetic markers of the original virus[2].

Studies of the molecular structure of ribonucleic acid have been carried out in the hope of learning something about the molecular mechanisms involved in these processes. However, until recently, it has been extremely difficult to obtain reliable structural information. Ribonucleic acid is somewhat unstable chemically, and most isolation procedures result in a degraded product so that we have only meagre information about the configuration of this substance[3].

However, a number of recent developments have made more promising the prospect of solving this problem. Grunberg-Manago and Ochoa[4] have discovered an enzyme which is capable of converting nucleotide diphosphates into polyribonucleotides. The resultant polymers resemble naturally occurring ribonucleic acid in that they have the same covalent ribose-phosphate backbone, and they have been shown to undergo a similar enzymatic hydrolysis[5]. X-ray diffraction studies of polymers containing all four of the purine and pyrimidine bases present in ribonucleic acid produce an X-ray diffraction pattern which is virtually identical with that produced by the naturally occurring substance[6]. Hence, these materials are ideal analogues for studying molecular configuration problems associated with ribonucleic acid. Since it is possible to control the type of purine or pyrimidine base in the polymer, we can learn how the base composition influences the configuration of the ribose-phosphate backbone. Of special interest, of course, are the hydrogen-bonding potentialities of the various bases, since the specificity of these interactions takes such a crucial role in maintaining the structure of deoxyribonucleic acid[7].

Polyadenylic Acid and Polyuridylic Acid

Among the first combinations of synthetic polynucleotides to be investigated structurally was polyadenylic acid plus polyuridylic acid. When these two elongated polymeric species meet in solution, they wrap around each other to form a two-stranded helical molecule, one strand of which is polyadenylic acid and the other polyuridylic acid[8]. The resultant 1 : 1 complex can be identified by its absorption spectrum in the ultra-violet as well as through its X-ray diffraction pattern. This diffraction pattern has many features in common with that produced by deoxyribonucleic acid, and it is believed that the adenine and uracil residues are joined together by the same hydrogen-bonding system which is found in deoxyribonucleic acid. This work further suggested that the ribonucleic acid backbone is capable of assuming the deoxyribonucleic acid configuration, that is, a helical form with the phosphate groups outside and a translation of 3·4 A., and a screw rotation of 36° between the hydrogen-bonded base pairs. The presence of the additional hydroxyl group on C'_2 of ribose modifies the configuration only slightly in this case.

An additional interaction was discovered between the two-stranded polyadenylic acid + polyuridylic acid molecule and a third strand of polyuridylic acid[9]. It has been shown that, in the presence of 0·012 *M* magnesium chloride, these interact in the ratio of one polyadenylic acid to two polyuridylic acid molecules, as measured by the ratio of reacting nucleotides. The interaction is accompanied by a change in the ultra-violet spectrum and sedimentation constant of the resultant material. It is believed that the third strand of polyuridylic acid has wrapped itself about the two-stranded polyadenylic acid + polyuridylic acid molecule, filling one of the helical grooves. Recently, a diffraction pattern has been obtained from material which was prepared under conditions in which the three-stranded complex forms. This pattern differs from that obtained with the two-stranded complex (unpublished work).

These results led to a search for other two- and three-stranded configurations among the synthetic polynucleotides. This communication reports the discovery of a new two-stranded helical configuration involving polyadenylic acid and polyinosinic acid, as well as a three-stranded complex involving an additional polyinosinic acid.

Polyinosinic Acid and Polyadenylic Acid

At the beginning of this investigation, I was informed by Prof. Paul Doty, of Harvard University, that he had observed a "helix-coil transition" in the system polyadenylic acid and polyinosinic acid (personal communication).

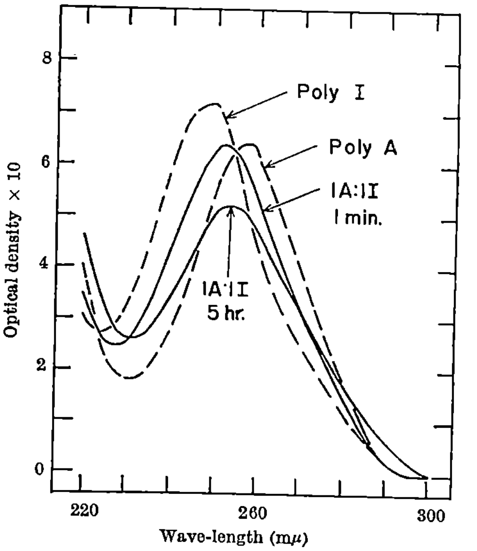

Fig. 1. Broken lines show the absorption spectra of polyadenylic acid (poly A) and polyinosinic acid (poly I) before mixing. The solutions are both in 0·05 *M* sodium chloride, 0·001 *M* sodium cacodylate at *p*H 6·8, $T = 23°$ C. The solid lines show the absorption spectrum of a 1 : 1 mixture (1 A : 1 I) 1 min. after mixing, and at 5 hr. As the complex forms, there is a drop in the optical density and a shift of the maximum and minimum

The polynucleotides used in my investigation were polymerized from nucleotide diphosphates and the enzyme polynucleotide phosphorylase from *Azotobacter vinelandii*. The highly purified enzyme (specific activity 113 units) was kindly supplied to me by Prof. S. Ochoa. Polymers were prepared during a two-hour incubation period and harvested by precipitation with cold ethanol followed by dialysis at 5° C. against 5×10^{-3} *M* sodium chloride and subsequent lyophilization. The sodium salt of the polynucleotides was used for all experiments.

Extinction coefficients were measured by assaying the ribose content of the solutions[10]. In 0·1 *M* sodium chloride, 0·01 *M* sodium cacodylate at *p*H 6·8, the molar extinction coefficient per nucleotide for polyadenylic acid is 9,180 at 259 mμ, and for polyinosinic acid it is 10,300 at 250 mμ.

The interaction between these two molecular species is best seen spectrophotometrically. In Fig. 1, the ultra-violet absorption spectra are plotted for equal concentrations of the individual polymers (dashed lines). These solutions are both in 0·05 *M* sodium chloride, 0·001 *M* sodium cacodylate at *p*H 6·8. When they are mixed together in a 1 : 1 ratio, spectra are observed as shown by the solid lines. At 1 min. after mixing, the resultant absorption spectrum curve lies half-way between the curves for the individual materials. However, the resultant spectrum changes with time. Equilibrium is obtained by 5 hr., at which time the final curve has dropped considerably as shown in Fig. 1. At equilibrium, the spectrum has shifted somewhat and has a new maximum at 254 mμ and a minimum at 231 mμ. The final optical density at the maximum has decreased by 18 per cent when compared to the starting point, and half this drop has occurred in approximately 20 min. under these conditions. Such a lowering of the optical density is called the 'hypochromic effect' and usually refers to the decrease in optical density which is attendant on the polymerization of nucleotides to form nucleic acids. In the synthetic polynucleotides, changes in the hypochromic effect

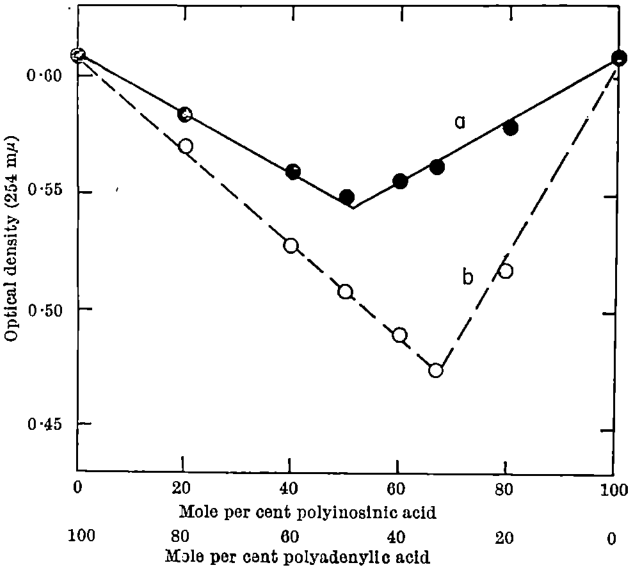

Fig. 2. Optical density at 254 mμ of mixtures of polyinosinic acid and polyadenylic acid. The conditions are the same as in Fig. 1. All points refer to the same total concentration of nucleotide phosphate. The solid curve (*a*) is obtained at 31 min. and the broken curve (*b*) at 5 hr. The minimum shifts from 50 per cent polyinosinic acid in (*a*) to 67 per cent in (*b*)

have been used as a convenient index for following the course of a reaction. Thus, for example, the reaction between polyadenylic and polyuridylic acids results in a similar lowering of the optical density in the ultra-violet[8,11,12].

The stoichiometry of the reaction can be determined by measuring the drop in optical density at a given wave-length as a function of composition. In Fig. 2, the optical density at 254 mμ is plotted as a function of mole ratio of polyadenylic acid to polyinosinic acid. The upper curve, *a*, is obtained 31 min. after mixing two standard solutions, both of which are in 0·05 *M* sodium chloride, 0·001 *M* sodium cacodylate, *p*H 6·8. In all these mixtures, the total concentration of nucleotide phosphate was kept constant, but the relative amounts of the two species vary. At 31 min. a minimum in the optical density is seen near 50 per cent, that is, a 1 : 1 mixture of polyinosinic and polyadenylic acids.

However, if these same mixtures are allowed to stand until equilibrium is reached, the curve changes further (Fig. 2, *b*). At equilibrium, the minimum has shifted to 67 per cent polyinosinic acid, suggesting the formation of a 2 : 1 complex involving two polyinosinic acid molecules and one polyadenylic acid molecule.

The formation of these two complexes is controlled by the ionic strength of the medium. As the salt concentration is decreased, the rate of the reaction decreases. Thus, in 0·01 *M* sodium cacodylate without added sodium chloride, only the 1 : 1 complex forms (Fig. 2, *a*) after 18 hr. On the other hand, in 0·1 *M* sodium chloride, the minimum at 50 per cent is seen clearly only until 40 sec. after mixing. Following that, the optical density – composition curve begins to shift, and the sharp minimum at 66 per cent polyinosinic acid is seen clearly after 4 min. At very high salt concentrations, for example, 1 *M* sodium chloride, no reactions occur. This is probably due to an alteration in the polyinosinic acid molecule and will be discussed in greater detail in another paper dealing with the structure of polyinosinic acid.

Further evidence for the formation of these complexes can be obtained from an ultracentrifuge investigation. For these studies, a 'Spinco' model *E* ultracentrifuge was used in a form modified for ultra-violet absorption measurements. In this way, concentrations were used near $6 \times 10^{-5} M$ in nucleotide phosphate and sedimentation constants were independent of concentration. Polyadenylic acid in 0·05 *M* sodium chloride and 0·001 *M* sodium cacodylate at *p*H 6·8 had a mean sedimentation coefficient (S_{20}) of 7·2, whereas the polyinosinic acid had a value of 8·6 under the same conditions. A 1 : 1 mixture of these had an average $S_{20} = 10{\cdot}4$ at equilibrium. However, an equilibrium mixture of 2 polyinosinic acid to 1 polyadenylic acid had an average $S_{20} = 14{\cdot}7$.

The experiments cited above demonstrate the formation of complexes between polyadenylic and polyinosinic acid. In order to obtain information about the detailed molecular configuration of these complexes, an X-ray diffraction investigation was carried out.

X-Ray Diffraction Studies

A 1 : 1 mixture of sodium salts of polyadenylic acid and polyinosinic acid was prepared by adding together weighed amounts of the dry material. The mixture was dissolved in distilled water without any added salt. Under these conditions, the solution had only the residual sodium chloride from the final dialysis in the preparation of the polymers. At this low salt concentration, only the 1 : 1 complex forms, as described above. After reacting at room temperature for one hour, the solution was lyophilized. The resultant dried fibrous mixture was then moistened until it became sticky and from this were drawn long, tough fibres which upon drying became brittle and highly birefringent ($\Delta n = -0{\cdot}09$). X-ray diffraction photographs were taken using an intense beam of X-rays 100μ in diameter (Hilger 'Semi-Micro' X-ray Tube Stand).

Fig. 3 shows a diffraction photograph obtained at 66 per cent relative humidity in a helium-filled camera. The distribution of scattering intensity is characteristic of a helical structure, as shown by the fact that the innermost maxima on the first, second, and third layer lines lie approximately on straight lines radiating from the origin. In addition, there is a large area on the meridian which is empty. In some respects, the diffraction photograph is similar to that produced by the *B* form of deoxyribonucleic acid[13].

There are two fairly strong reflexions on the equator and several weaker ones. These appear at distances which indicate a hexagonal lattice with $a = 24{\cdot}4$ A. By measuring the layer line spacing, it can be shown that the pitch of the helix is 38·8 A. The specimen was tilted slightly in Fig. 3 to show the upper layer lines more clearly. Several layer lines appear near the meridian in the region of 3–4 A. From these it appears that there is a meridional reflexion near 3·4 A. Hence the fundamental screw repeat for the helix is a translation of 3·4 A. and a rotation of

$$\left(360^\circ \times \frac{3{\cdot}4}{38{\cdot}8}\right) = 31{\cdot}5^\circ$$

The reflexions in the 3·4-A. region are undoubtedly due to the stacking of the planar purine bases at right angles to the fibre axis. This interpretation is

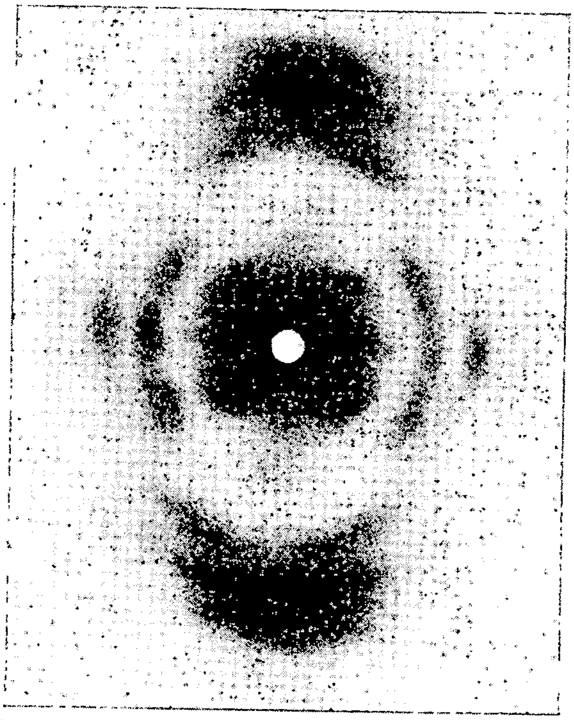

Fig. 3. X-ray diffraction photograph of a fibre of polyadenylic acid plus polyinosinic acid (1 : 1). The fibre is at a relative humidity of 66 per cent in a helium-filled camera, and is tilted slightly from the vertical

compatible with the observed high negative birefringence.

Cochran, Crick and Vand have analysed the diffraction patterns produced by helical molecules[14]. They have shown that the structure factor for a given layer line is the sum of a series of terms each of which contains a Bessel function $J_n(2\pi rR)$, where r is the radius of an atom, and R is the radius in reciprocal space. In the nucleic acids, the diffraction pattern is usually dominated by the contributions of the phosphate groups ; hence it is possible to carry out a very approximate analysis by considering their contributions alone. In this approximate analysis the positions of the innermost maxima on layer lines 1, 2, and 3 can be equated to the first maxima of $J_n(2\pi rR)$, where n is 1, 2 or 3, respectively. Such an analysis yields a weighted 'average' scattering radius of 9·5 A. This strongly suggests that the phosphate groups are on the outside of the molecule, as in deoxyribonucleic acid.

Discussion

With the ribose-phosphate backbone helically arranged on the outside of the two-stranded complex, it is necessary to determine the arrangement of the two purine bases relative to each other in the centre of the molecule. The diffraction data clearly indicate that these planar groups are oriented at right angles to the fibre axis, and it is necessary to consider the manner in which they might be linked together by hydrogen bonds. Before this can be done, one must know the tautomeric forms which exist under the conditions in which the polynucleotides interact.

It has been generally assumed that the adenine residue in the nucleic acids is in the amino-form. A recent study of the infra-red spectrum of adenylic acid in solution has confirmed this assignment[15]. Information concerning the tautomeric form of inosinic acid comes from a variety of sources. Spectroscopic and infra-red evidence has been presented by Brown and Mason[16] in a study of several monohydroxy purines. They have shown that the oxygen on position 6 is probably in the keto-form in 9-methyl hypoxanthine. Crystallographic studies on the somewhat related guanine residue[17] show a ketonic oxygen on position 6 in the solid state. In addition, work now in progress on the structure of polyinosinic acid also indicates a keto-form for the oxygen.

Pairing of the adenine and hypoxanthine bases to form a structure of the type suggested by the X-ray diffraction pattern can most easily be done by the hydrogen-bonding shown in Fig. 4. The amino-group of adenine is linked to the keto-oxygen of hypoxanthine, while both purine nitrogen 1 atoms are linked by hydrogen bonds. These hydrogen-bonded purine pairs are helically stacked according to the screw dimensions cited above, with the phosphate ribose chain on the outside. Fourier transforms have been calculated for models of this type and will be reported elsewhere.

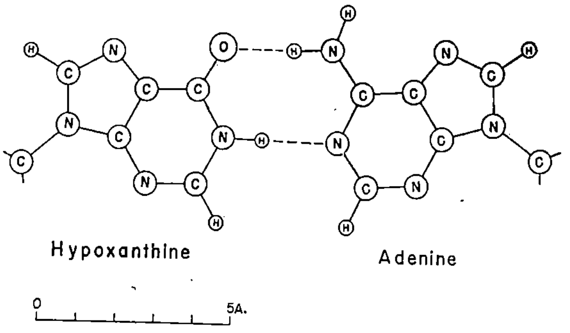

Fig. 4. Hydrogen bonding between hypoxanthine and adenine bases. One carbon atom from the ribose sugar is shown

At the present time, there is only spectroscopic and ultra-centrifugal evidence for the existence of the three-stranded complex. However, we know that the two-stranded molecule is helical, and by analogy with the system of polyadenylic acid plus polyuridylic acid, it is quite likely that the third strand lies in the helical groove of the two-stranded molecule. It is possible, for example, that the second hypoxanthine base is linked to the adenine residue by two hydrogen bonds (hypoxanthine keto-oxygen and nitrogen 1 bonded, respectively, to adenine amino-nitrogen and nitrogen 7 of the imidazole ring). A somewhat similar arrangement has been suggested for the second uracil chain, which is bonded to the two-stranded polyadenylic acid plus polyuridylic acid complex[9].

While inosinic acid is believed to be a precursor of adenylic acid as well as guanylic acid, it has not been found in ribonucleic acid itself. However, it is related structurally to guanylic acid in that it has the same keto-oxygen on carbon 6 of the purine ring, even though it lacks the amino-group on carbon 2. It is less closely related to adenylic acid, since substituting a keto-group for an amino-group radically alters the hydrogen bonding possibilities of the purine. This is, of course, readily seen by noting the great difference between the diffraction pattern of polyinosinic acid + polyadenylic acid relative to that of polyadenylic acid by itself. In the latter case, the structure is believed to be a two-stranded helix with each chain organized around an axial two-fold rotation axis[18]. The amino-group has a position in that structure which could not be substituted by the oxygen on the hypoxanthine base.

The studies reported here have shown that mixtures of polynucleotides are capable of forming hydrogen-bonded helical structures which are susceptible to crystallographic analysis. Just as the structure of the fibrous proteins was finally solved by working on the simpler synthetic polypeptides, it is hoped that structural analysis of synthetic polyribonucleotides will aid the solution of the structure of ribonucleic acid and facilitate our understanding of its function.

I would like to acknowledge the generous assistance and advice of Dr. D. R. Davies and the technical assistance of Mrs. J. Johnson. I am indebted to Prof. S. Ochoa and Miss P. Ortiz for the supply of polynucleotide phosphorylase, and for information concerning its use.

THE BAND THEORY OF METALS

A SHORT and valuable conference was held in the Imperial College of Science and Technology, London, on December 19 and 20 on "The Band Theory of Metals and the Structure of the Fermi Surface". It was attended by about 240 members of the Physical Society and visitors, including Prof. Vonsovski from the U.S.S.R. The chief value of the conference must lie in the way in which it has drawn together many aspects of the subject. In the years 1928–35, almost the whole theory of metals was fairly satisfactorily sketched in outline, and we were often reminded of this during the conference. Since then, much work has gone into filling in the many gaps that remained. The different threads have now been drawn together again into a more comprehensive theory of metals and into a united research front. There were several review papers of various experimental techniques and theoretical developments, emphasizing what relevance the results obtained from them had for the theory of metals as a whole. There was also a good mixture of theoretical and experimental papers, and much emphasis on turning all this to good account by trying to understand, in detail, the properties of at least a few individual metals. As a further elaboration of this theme, the following thoughts remained in the mind of one participant after the conference. In some places the remarks go beyond what was actually said in the formal sessions.

Prof. N. F. Mott opened the conference with a paper on "Band Theory and Ferromagnetism", which brought out the distinct types of wave function that we use in different circumstances to describe electrons in metals. In the earliest development of the subject, the wave functions of the individual electrons were taken as waves $\psi_{\mathbf{k}}$ (with wave vector $\mathbf{k}$) extending throughout the crystal, and the wave function of the whole metal was written as a product or as a single determinant:

$$\Psi_{\text{Bloch}} = (N!)^{-1/2} \mid \text{determinant of the } \psi_{\mathbf{k}}\text{'s} \mid \qquad (1)$$

where N is the total number of conduction electrons in the metal. This we shall refer to as the Bloch picture. Because of the periodicity of the lattice, $\mathbf{k}$ is restricted to a certain region in k-space known as the Brillouin zone. The energy $E(\mathbf{k})$ varies continuously with $\mathbf{k}$ in each zone. Because of the exclusion principle, all the states below the Fermi level E_F are occupied by electrons. The surface in k-space:

$$E(\mathbf{k}) = E_F \qquad (2)$$

is the boundary between the occupied and unoccupied levels, and it determines many of the properties of the metal. The earliest successes of this theory include the resolution of the classical difficulty that the electrons in a metal seem to be free enough to give a high conductivity and yet contribute very much less than $\frac{3}{2}kT$ each to the specific heat. It also explains the qualitative difference between a metal and an insulator, and how semi-metals like bismuth can exist with an apparent number of 10^{-5} free electrons per atom. On this sort of picture, most of the present theory of metals is based, and Prof. Mott reminded the audience how it could account for the ferromagnetism of some metals like cobalt and nickel. However, he emphasized that in other cases we are driven to use wave functions of a qualitatively different type, namely, the Heitler–London type of function. In this picture each electron is more or less tightly bound to a particular atom (position $\mathbf{R}_n$), and moves in an orbital $\psi(\mathbf{r} - \mathbf{R}_n)$ localized around this atom. The whole wave-function is:

$$\Psi_{HL} = (N!)^{-1/2} \mid \text{determinant of } \psi(\mathbf{r} - \mathbf{R}_n)\text{ 's} \mid \qquad (3)$$

In this picture the concept of a Fermi surface does not arise. Prof. Mott mentioned different kinds of ferromagnetics and anti-ferromagnetics which are thought to correspond to the two types of wave function. In particular, the ferromagnetic $3d$-electrons in iron, and similarly the $4f$-electrons in gadolinium metal, should be described by the Heitler–London type of wave function (3), in contrast to cobalt and nickel. This view is supported, for example, by data on the saturation magnetic moment of iron–copper alloys. The moment is just 2·22 Bohr magnetons multiplied by the number of iron atoms, in accordance with the view that each magnetic electron is localized around an iron atom and is therefore removed when the iron atom is replaced by a non-magnetic copper atom. The behaviour is quite different from that of cobalt–copper and nickel–copper alloys. Later in the conference, these ideas were developed more fully and more experimental evidence was brought forward by the following: W. M. Lomer and W. Marshall, "Electronic Structure of Ferromagnetic Alloys"; Miss Y. Cauchois, "X-ray Spectroscopy of Metals"; B. R. Coles, "Electrical Resistivity and Electronic Structure". There was also ample time on the programme for the lively discussion which recurred throughout the conference, and in which many other people contributed. J. R. Schrieffer outlined how wave functions, which are quite different again from either (1) or (3), are being used in "Recent Developments in the Theory of Superconductivity".

All the rest of the conference was devoted to non-ferromagnetic good metals like the alkalis, and copper, aluminium and lead, and their alloys. Even for a good metal, the Bloch type of wave function (1) cannot be regarded as satisfactory, in spite of its many successes. For a free-electron gas which can be worked out in detail, it gives a zero density of states at the Fermi-level, in contrast to all the experimental evidence, which demands a finite one. As R. S. Leigh pointed out in his paper on "Correlation in the Free Electron Gas", this difficulty can be traced to the long-range ($1/r$) nature of the Coulomb potential. The use of the Bloch wave function (1) implies that each electron moves in its orbital ψ_k independently of all the other electrons. This cannot be correct, for the Coulomb repulsion between two electrons is quite strong and must influence their motion so as to keep them from getting too close to one another. This is called 'correlation'. It is closely allied to the longitudinal plasma oscillations of the electron gas as a whole, for which the Coulomb repulsion is also responsible. By starting from these plasma oscillations, a more complicated theory of the free electron gas can be built up following the work of Bohm and Pines, which gives reasonable agreement with experiment for the alkali metals. Mr. Leigh discussed how these results could also be obtained from a somewhat different point of view.

If this left the conference momentarily stunned by the complication of the theory of even a free-electron gas, despondency was soon dispelled. In spite of the complications of correlation, the wave function for the free-electron gas can be written (to a good degree of approximation):

$$\Psi = (N!)^{-1/2}\ \chi\ |\ \text{determinant of } \psi_k\text{'s}\ | \qquad (4)$$

This is very similar to (1), while the extra factor χ, called the plasma term, describes the correlation of the electrons. The determinant again describes N particles moving independently of one another through the metal. But these particles are no longer simple electrons. The Coulomb repulsion means that each electron is surrounded by a denuded region in which other electrons are unlikely to be. Because of the positive charge of the ions making up the lattice, this denuded region has on the average a positive charge. The particles now consist of the electrons together with the denuded region around each one. Each particle is therefore electrically neutral, and there is now no long-range Coulomb force between them. Only a weak short-range force remains. For this reason there is little correlation and the particles can be described as moving nearly independently. The wave function (4) thus contains a single determinant of extended orbitals, ψ_k. This removes the deficiencies of the simple Bloch theory based on (1), and yet at the same time retains its successes. The concepts of the wave vector **k**, Brillouin zones and Fermi surfaces remain, and so does our interpretation of physical properties in terms of them. The theme was developed further by J. Hubbard in "Description of the Electron Gas in Terms of the Independent Particle Model". Using this model as a basis for the first time, V. Heine described a "Self-consistent Band Structure Calculation for Aluminium". In this calculation he was also able to overcome some of the mechanical difficulties that have always made calculations of band structure so unreliable, and to obtain reasonable agreement with what is known experimentally about the Fermi surface in this metal. W. M. Lomer presented a paper for Mrs. E. C. Ridley on the energies of the "6*s*-, 6*p*-, 7*s*-, 7*p*-, 6*d*-, 5*f*-Wave Functions of Metallic Uranium". From this the six valence electrons would appear to be predominantly in the 5*f*-band. Prof. R. Eisenschitz described how one could calculate the "Electronic Levels of Disordered Structures".

We may summarize by saying that for various experimental and theoretical reasons, some of which have been mentioned above, we believe that the concepts of Brillouin zones and Fermi surface have real validity and physical significance, in spite of the complications of electron correlation. Most of the conference was therefore devoted to methods of determining experimentally the shape of the Fermi surface in a given metal (as well as other aspects of the band structure), since this is the key to an understanding of most of the electrical and magnetic properties of the metal. The de Haas–van Alphen effect, discussed by Dr. D. Shoenberg in a paper of that title, would appear to be in principle the most powerful tool for obtaining the shape of the Fermi surface experimentally. The observations give the area of cross-section of the surface normal to the magnetic field, as a function of the field direction, and from this the shape of the surface can be calculated. If the Fermi surface consists of several pieces in different zones, then each piece can be so determined. A. Gold described how "The de Haas–van Alphen Effect in Lead" had enabled him to map out by this method the Fermi surface in lead, which consists of several pieces in the second, third and fourth zones. It is noteworthy how close the band structure is to what one obtains if the Fermi surface is taken as a sphere containing four electrons per atom (free-electron gas model) and the pieces of the sphere are fitted correctly into the zone scheme. This work made us feel that perhaps all other methods could be put in a subsidiary category; but Dr. Shoenberg reminded us that the de Haas–van Alphen effect has its 'blind spots', where it does not at present seem to be applicable. For example, the effect has not yet been detected in any alkali or noble metal. For these metals other methods must be used, and Dr. A. B. Pippard discussed "The Anomalous Skin Effect" with particular reference to determining the Fermi surface of copper. He concluded that the Fermi surface either just touches or just does not touch the zone face in the (111) direction. Circumstantial evidence would favour the former. Dr. R. G. Chambers presented a paper on "Cyclotron Resonance in Metals". The resonance could in principle determine the effective mass at all points on the Fermi surface, as in semiconductors, but some of the differences from cyclotron resonance in semiconductors were pointed out. So far only bismuth has been studied systematically, but the resonance has also been detected in tin.

This more or less concludes the most powerful tools, in which some quantity is measured as a function of orientation for all directions in space so that much detailed information is obtained. In contrast, the following determinations give a specific piece of information, which may not be obtainable in any other way, but which is an average over the whole band structure or the whole Fermi surface. J. A. Catterall discussed "X-ray Emission from Alkali Metals" with particular reference to lithium. He concluded that the maximum in the emission spectrum definitely came below the Fermi level. Miss R. Coldwell-Horsfall presented a paper on the "Electrical Conductivity Tensor and the Fermi Surface". There was considerable discussion about the density of states at the Fermi-level and related experimental quantities such as the electronic specific heat and the Knight shift. Papers on this were presented by Prof. H. Jones ("Experimental Data Related to Band Structure"); P. L. Smith ("Electronic Specific Heat of Simple Alloys"); L. E. Drain ("Nuclear Magnetic Resonance in Ag–Cd Alloys"). Prof. Jones pointed out that the electronic specific heat measurements require a density of states about 50 per cent higher than one would expect, and gave a theory of how this might be accounted for. The results presented by P. L. Smith and L. E. Drain showed how much more difficult it is to make sense of the results for alloys, and there was considerable discussion about this.

At the end of the first day of the conference, Prof. L. C. Jackson helped to take our minds off metals when he delivered the Duddell Lecture of the Physical Society on "Measurements of the Thickness of the Helium Film". The subject of this very interesting lecture was particularly appropriate to the conference since many of the experimental methods discussed involve low-temperature techniques. V. HEINE

OBITUARY

Prof. R. W. Whytlaw-Gray, O.B.E., F.R.S.

THE death of Robert Whytlaw-Gray on January 21 at the age of eighty removes one more link with the days when the Curies and Ramsay were rejuvenating inorganic chemistry. He was a student of Lord Kelvin and then a research worker in Ramsay's laboratories, where he developed a life-long interest in the physical properties of gases and great experimental skill in their manipulation. This led him to work on molecular and atomic weights, and in 1906 while in Bonn he re-determined the atomic weight of nitrogen by gravimetric analysis of liquefied and fractionated nitric oxide and by density determination. Whytlaw-Gray then returned to University College, London, and in collaboration with Ramsay, determined the atomic weight of niton. This was an outstanding achievement. The density was determined with a modified Steel–Grant micro-balance and about $0{\cdot}1$ mm.^{3} of niton.

In 1914 he became senior chemistry master at Eton, where his steadiness of purpose enabled him to carry out a considerable amount of research. In 1915 and for long afterwards he engaged in confidential work on toxic and other smokes, their physical properties and the methods by which their effects could be countered. In the fifth Liversidge Lecture, entitled "The Process of Coagulation in Smokes", delivered before the Chemical Society in 1935, he discussed his own and other work on this subject, and in 1936, with H. S. Patterson, published a book entitled "Smokes". His expert knowledge was again utilized by the Ministry of Supply in 1939 and he formed a group of about twelve workers at the University of Leeds to study problems connected with chemical warfare.

Whytlaw-Gray had been appointed to the chair of chemistry at Leeds in 1922 in succession to Arthur Smithells. His research activity there was intense and he developed a buoyancy micro-balance of high accuracy and employed it in the determination of the atomic weights of carbon, fluorine, nitrogen, sulphur and silicon by the use of gaseous compounds of these elements. He was elected to fellowship of the Royal Society in 1928. After ten years in laboratories designed by T. E. Thorpe, he entered the new building which he, Dawson and Ingold had so successfully planned.

His regime was marked by tact, by careful consideration of the views of others (especially when he differed from them), by an informed appreciation of the needs of other scientific and technological departments and by a firm adherence to those principles which guided his personal and scientific life. On his retirement the Senate was "happy to learn that he is to continue his investigations in the Chemistry Department of which the spirit no less than the fabric owes so much to his unselfish devotion". One of his colleagues said of him: "It may be that some aspects of his character are derived from, or at least, related to the quiet detachment of the exact experimentalist —his unruffled calm to the poise and exactness of his own micro-balances".

When Whytlaw-Gray left Leeds in 1950 the University conferred upon him the degree of D.Sc. *honoris causa*. In recent years he worked at the Imperial Chemical Industries' Akers Laboratory, Welwyn, on the isothermals of xenon at low pressures and also on the normal density of the gas. The communication, with Dr. G. A. Bottomley, published in *Nature* as recently as December 7, 1957, is characteristic of his life-long struggle towards perfection in measurements of the properties of gases and vapours. Some earlier work on the deviation from ideality of vapours at low pressures was shown to be subject to significant error due to adsorption. This they reduced to a constant minimum in a re-designed differential compressibility apparatus, mainly by avoiding passage of mercury through greased stopcocks. The PV/P graphs for benzene vapour, after correction for adsorption, then deviated from straight lines by less than two parts in 10^5.

His colleagues and friends will be happy to think that he was able to continue in active work to the end of his long life. He rarely spoke about himself, but it was clear to those who knew him well that he served God 'with a quiet mind'.

FREDERICK CHALLENGER

NEWS and VIEWS

British Association : New Lecture for Children

Prof. J. Rotblat, professor of physics in the University of London, at St. Bartholomew's Hospital Medical School, will lecture on "Peaceful Uses of Atomic Energy" at Northgate Grammar School, Ipswich, on February 25. The lecture will be given in two sessions to different audiences, and will be illustrated by films and demonstrations ; there will also be visits to an atomic energy exhibition which the Atomic Energy Commission is arranging in Northgate School for the whole week. It is expected that some nine hundred children will hear the lecture, arrangements for which have been made by Mr. L. R. Missen, chief education officer, East Suffolk, in co-operation with the British Association for the Advancement of Science, as part of the new campaign of the latter to present science to the people.

Pure Mathematics at Cambridge :

Prof. A. S. Besicovitch, F.R.S.

Prof. A. S. Besicovitch, Rouse Ball Professor of mathematics in the University of Cambridge, retires this year, having reached the age of sixty-seven. He was elected to the chair in 1950, succeeding J. E. Littlewood, who was the first holder. He has recently worked at a number of problems in real-function theory, in particular the theory of area and extremal problems. He has directed research in these topics but he has not restricted his teaching to graduates. To the pleasure and profit of those working for the Mathematical Tripos, he has organized seminars for them. He has also maintained a flow of 'Contest Problems', at which an aspiring young analyst may try his skill with the possible reward of a public announcement : 'Perfect solution of problem was made by *A. B. C.*'. Prof. Besicovitch has been credited with the remark that a mathematician's reputation rests on the number of bad proofs that he has given—in the sense that pioneer work can be rough. He preserves unimpaired his mastery of intricate mathematical situations, and many more good and bad proofs are expected from him.

Prof. H. Davenport, F.R.S.

Prof. Harold Davenport, who has held since 1945 the Astor chair of pure mathematics at University College, London, will succeed Prof. Besicovitch on October 1. Born in 1907, he took degrees at Manchester and at Cambridge, becoming a Fellow of Trinity College. He was elected to the Royal Society in 1940. Most of his work has been in some branch or other of the theory of numbers. His early papers dealt with problems of the analytic theory, following the methods of Hardy and Littlewood. Later he turned to Diophantine approximation and the geometry of numbers. He has written about a hundred papers and some of them give solutions of problems which had been long outstanding. To mention only one example, Minkowski's problem, of the minimum value of the product of three linear forms the determinant of which is 1, was solved with consummate skill and elegance in 1938. He has now in course of publication some fundamental results on the minima of indefinite quadratic forms. Prof. Davenport has built up a strong school of research at University College and there are mathematicians of international repute who owe their early guidance and encouragement to him. He is one of the founders of the journal *Mathematika*, and he has just been elected president of the London Mathematical Society. One of the most resourceful English pure mathematicians of his generation, he is expected to solve with distinction as difficult a problem as he has yet tackled—that of succeeding Littlewood and Besicovitch.

Aircraft-propulsion Studies at Cranfield :

Mr. A. G. Smith

Mr. A. G. Smith, who has been appointed to the chair of aircraft propulsion in the College of Aeronautics, Cranfield, entered the Royal College of Science and Technology, London, as a Royal Scholar in 1937 and graduated with a first-class degree in physics in 1939. He studied aeronautics for a postgraduate year at the City and Guilds College, London, and then worked for Blackburn Aircraft, Ltd., at Brough, until 1942, when he joined Power Jets, Ltd. During the rest of the Second World War he was engaged on research and development work on various Whittle engines, and particularly on compressor aerodynamic development. He joined the National Gas Turbine Establishment on its formation and worked on theoretical and experimental aspects of turbine cooling. In 1952 he was appointed reader in the University of London in applied thermodynamics with special reference to gas turbines. Since that time, besides carrying out research on aerodynamic and heat-transfer problems, he has run a very successful postgraduate course in gas-turbine technology at the City and Guilds College. He has published papers on turbine cooling and on heat transfer, aerodynamic and thermodynamic matters related to gas turbines.

Horticulture at Nottingham :

Prof. J. P. Hudson, O.B.E.

The newly created chair of horticulture at the University of Nottingham has been filled by the appointment of Dr. J. P. Hudson, the present head of the Department of Horticulture, who thus becomes the first student of the old Midland Agricultural College to succeed to a chair. Dr. Hudson has had a varied career. Entering college in 1927, he graduated with the degree of B.Sc. (Hort.) of the University of London in 1930, and then served one year as student assistant in the Agricultural Economics Department at the Midland Agricultural College. From then until the outbreak of war in 1939 he was engaged in practical horticulture, at first in industry but later as horticultural instructor at the East Sussex School of Agriculture. During the War he served with considerable distinction in the Royal Engineers and in 1942 spent six months in the United States organizing a bomb disposal school. For the last four years of the War he was engaged on bomb disposal research and experimental work, and was made O.B.E. and awarded the George Medal (and Bar) for his services. Indeed, he must be one of the few professors to discover an aptitude for research, six years after leaving the university, on a material where a decisive result might well have the rather unusual effect of terminating one's research career.

Leaving the army on the termination of hostilities with the rank of major, he proceeded to New Zealand to take charge of the Dominion Horticultural Station at Levin, where he was responsible for horticultural extension work in the market garden, glasshouse and nursery industries. He returned to England in 1948, as lecturer in horticulture at his old institution, now become the Faculty of Agriculture of the University of Nottingham. He was appointed head of the Department of Horticulture in 1953, after being acting head for two years. Since 1951, Hudson has been steadily developing his Department from that of a college concerned largely with certificates and diploma courses into a University Department of Horticulture. The depression in the horticultural industry which led to a fall in the number of candidates coming forward for degree courses made this a difficult period for the change, but Hudson successfully piloted his Department through, initiating at the same time a vigorous research school. The theme has been the influence of cultural practices on plant growth, and his contributions in two fields, namely, the control of soil moisture for glasshouse crops, and the influence of environment on the growth of biennial crops, have shown his excellent grasp of the fundamental principles involved, and the manner in which they may be applied to the benefit of the horticultural industry.

Dean of Graduate Studies at the Rockefeller Institute, New York: Dr. Frank Brink, jun.

Dr. Frank Brink, jun., has been appointed to the newly created office of dean of graduate studies at the Rockefeller Institute. Dr. Brink is a member and professor of the Institute, doing research work on biophysics. As dean, he will assist the president and the faculty committee on educational policies in the development of graduate education. The charter of the Rockefeller Institute was amended in November 1954 so that the degrees of Ph.D. and M.D. could be granted with the authority of the Regents of the University of the State of New York. The Institute is now in its third year as a graduate university and has a limited enrolment of graduate students. Dr. Brink has been closely associated with the education programme of the Rockefeller Institute since its inception in 1954. Since 1956 he has served as secretary of the Trustees' Committee on Educational Policies under the chairmanship of Dr. Robert F. Loeb, of the Columbia University College of Physicians and Surgeons. Dr. Brink graduated from Pennsylvania State University in 1934. After a year of graduate work at the California Institute of Technology, where he received the degree of M.S., he began graduate work in biophysics at the Johnson Foundation at the University of Pennsylvania, where he received the degree of Ph.D. in 1940. He was later instructor in physiology at the Cornell University Medical College, assistant professor of biophysics at the University of Pennsylvania, and associate professor of biophysics at Johns Hopkins University. Since 1953 he has been at the Rockefeller Institute, where he has worked in the field of biophysics and neurophysiology in association with Dr. D. Bronk, the president. He is also a member of the board of editors of the *Journal of General Physiology* and is on the editorial board of the *Journal of Cellular and Comparative Physiology* and the advisory board of the *Journal of Neurochemistry*.

Baghdad Pact Nuclear Centre

The Baghdad Nuclear Training Centre was established in 1956 by the member countries of the Baghdad Pact. It is at present concentrating on the practical applications of radioisotopes to the problems of Middle Eastern countries and is organizing intensive short courses in the uses and techniques of these materials. Two instructors each from Iraq, Iran, Pakistan and Turkey were trained at Harwell during 1956, and the United Kingdom also assisted by the gift of equipment and the loan of staff to supervise, teach and promote the development of the Nuclear Training Centre until local staff can assume responsibility. The first director of the centre, Mr. W. J. Whitehouse, was seconded from the U.K. Atomic Energy Authority in 1957 with four other members of the Authority's staff to prepare the Nuclear Training Centre, supervise the installation of British equipment there and to organize and assist in running the first course.

Mr. H. A. C. McKay of the Chemistry Division, Atomic Energy Research Establishment, Harwell, has now been appointed director of the Baghdad Pact Nuclear Centre from July 1958, in succession to Mr. W. J. Whitehouse. Mr. McKay, who was born in 1913, was educated at Balliol College, Oxford, and in 1935 was the Goldsmiths' Senior Scholar at the Institute for Theoretical Physics, Copenhagen. He was Beit Memorial Fellow at the Imperial College of Science and Technology, London, in 1937, and a demonstrator at King's College, London, in 1939. He served in the Royal Navy during the Second World War and in 1947 became a senior scientific officer in the Chemistry Division at Harwell, where he was appointed group leader of the Heavy Element Group in the Chemistry Division in 1954. He has specialized in solution chemistry.

World List of Scientific Periodicals

One result of the advances and developments in science and technology in recent years is reflected in the vast number of new scientific and technical journals that have appeared, together with an increase in the output of periodical publications throughout the world. This, combined with the fact that the third edition of the "World List of Scientific Periodicals" will soon become out of print, has led to active preparation for the issue of a fourth edition. In the new edition, brought up to date to include the new scientific and technical periodicals that have appeared in the past decade, the abbreviations of titles, where necessary, will be modified to conform with the International Standards Organization Recommendation *R*4 of the International Code for the Abbreviation of Titles of Periodicals. The system recommended by the Royal Society for the transliteration of Russian, Serbian and Bulgarian for bibliographic purposes will also be adopted.

Since the location of the periodical publications available for reference in libraries is of the utmost importance to research, the librarians of the 247 libraries who contributed to the last edition are being requested to participate in the new edition of this important bibliographical work of reference. They are asked to send the titles of journals not appearing in the third edition, with particulars of their holdings, and amendments or corrections to the entries of their holdings of the 46,000 titles contained in the last edition, to the Secretary, World List of Scientific Periodicals, c/o the Zoological Society of London, Regent's Park, London, N.W.1, from which office further information may be obtained.

Thermal Insulation of Houses

The Thermal Insulation (Dwellings) Bill which Mr. G. Nabarro introduced into the House of Commons on January 29, sponsored by members of both major political parties, extends the principle of the

Thermal Insulation (Industrial Buildings) Act of July 1957 to all new dwelling houses built in the United Kingdom after 1959. Mr. Nabarro said that on the evidence of the Egerton Committee's report of 1946 and of the Ridley Committee's report of 1952 we used on average five tons of coal or its equivalent per dwelling per annum, of which four tons were used for space- and water-heating services generally. He claimed that at least 25 per cent of this would be saved by proper insulation of houses. Accordingly, at an annual construction of 250,000 houses, an initial saving of 250,000 tons should be achieved, rising progressively to 5 million tons per annum at the end of twenty years. The minimum economy of £40 million per annum, at to-day's price, made investment in thermal insulation, which should not cost more than £8 on a £1,600 four-bedroom council house, well worth while.

Stars Month by Month

There are many people who have a general interest in the phenomena of the night sky and who need a simpler description of the visibility of the stars and planets than is found in the almanacs. To meet this need *The Times* produces an annual booklet. The latest edition, "The Night Sky 1958" (pp. 27. London: The Times Publishing Co., Ltd., 1958. 3*s.* net), gives charts for every month of 1958. Each chart shows the sky as it appears at 11 p.m. on the first day of the month together with the positions of the moon and planets. Each chart is accompanied by notes on the visibility of the planets and the phases of the moon for the month. There are notes on the eclipses which occur during the year, and some general explanatory notes. The booklet is well produced and the information which it contains clearly presented. The booklet is suitable not only for the general public but also for use by those schools, societies and clubs in which efforts are made to introduce young people to the phenomena of Nature.

Bishop's Stortford School Natural History Society

The value of school natural history societies and the contribution they can make to new knowledge is illustrated by the activity of the Bishop's Stortford College Natural History Society. Observations on the mistletoe by a senior boy, D. J. Cove, were noted in *Nature* (178, 779; 1956), and will now be included by the Forestry Commission in a new book on the diseases of forest trees. Besides the usual sectional reports, the latest issue of the Society's journal, *Coturnix*, contains details of studies on the larger fungi of the Bishop's Stortford district by J. W. Neal and the distribution of certain myriapods and crustaceans in organic debris during the winter months by M. Morton. Interesting observations on the reactions of certain myriapods to light, gravity, certain smells, water and oxygen were made by J. G. Pickard, who was able to show that the relatively high rate of respiration of the lithobiomorph centipede may be correlated with its observed restlessness; the low rate in the case of *Julus* with its observed sluggishness. A regional survey of the local sewage farm was made by R. G. Oakley, while P. H. King made continuous observations at Mersea Island, the centre of the oyster industry.

Extension of Primary Cell Walls

The mechanism of deposition and extension of primary cell walls has been further investigated by G. Setterfield and S. T. Bayley (*Canadian J. Bot.*, 35, 435; 1957). Walls of elongating parenchyma and epidermal cells of *Avena* coleoptiles and onion roots were studied by autoradiography, using sugars labelled with carbon-14, and by electron microscopy of thin transverse sections. The autoradiographs showed that deposition of cellulose takes place over the whole length of the cell, ruling out the possibility of bipolar tip growth. Autoradiographs of cells grown for short periods in labelled sugar gave no evidence of localized incorporation of the isotope around primary pit-fields, but rather indicated that deposition of microfibrils is finely dispersed over the entire wall surface. The thin sections revealed a marked change in wall structure as elongation proceeds. Walls of young cells contain only transversely oriented microfibrils, while older walls include an inner region of predominantly transversely oriented microfibrils bounded outside by a region with microfibrils showing an irregular transition to longitudinal orientation. The degree of longitudinal orientation in the outer region increases with length of cell. These results for thin walls are consistent with the multinet model for wall growth deduced by other workers from electron microscope studies on cell fragments. Thin sections have also revealed layering in several types of growing walls which is difficult to interpret on the basis of the multi-net model alone.

Graft Unions between Meristematic Tissues

Under the title of "The Regeneration of Severed Pea Apices", H. F. Gulline and R. Walker (*Australian J. Bot.*, 5, 129; 1957) have described successful graft unions between meristematic tissues in apices of the pea, *Pisum sativum* L. A technique for preventing desiccation of apices during and after the operations is described. Apical segments ranging from about 200μ down to 50μ in depth were successfully grafted back to their parent plant. The subsequent development of grafted apices was completely normal. These experiments show that a complete shoot can be regenerated from an apical segment less than one-thousandth of a cubic millimetre in volume, containing about 600 cells. This is smaller than any graft previously recorded. The morphogenetic interest of this investigation needs no emphasis.

U.K. Atomic Energy Authority: Appointments

Dr. H. Kronberger has been appointed director of research and development at the Industrial Group Headquarters at Risley, Lancashire, of the United Kingdom Atomic Energy Authority. He succeeds Mr. L. Rotherham, whose appointment as a member of the Central Electricity Generating Board was announced in *Nature* of January 4, p. 20. Dr. Kronberger, who is thirty-eight years of age, was chief physicist at Risley prior to his new appointment.

Mr. J. C. C. Stewart, formerly director of technical policy in the Industrial Group at Risley, becomes a deputy managing director of the Industrial Group. Mr. J. B. W. Cunningham, formerly deputy director (civil reactors), becomes director of industrial power in the Industrial Group. Dr. R. Hurst, formerly chief chemist in the Research and Development Branch of the Industrial Group at Risley, becomes director of the Dounreay Experimental Reactor Establishment. Mr. D. S. Mitchell, formerly director of administration, becomes director of personnel and administration in the Industrial Group. These appointments, which took effect on February 1, mark a first stage towards implementing recommendations made by the Committee appointed by the Prime Minister under the chairmanship of Sir Alexander Fleck to examine the organization of certain parts of the Authority. Further appointments will be announced in due course.

Mr. D. W. Fry, chief physicist at Harwell, has been appointed a deputy director of the Atomic Energy Research Establishment and took up his new post on February 17.

Prof. Heinrich Balss

Dr. J. Théodorides of the University of Paris has written to say that, in the obituary notice of Prof. Heinrich Balss, which appeared in *Nature* of December 21, 1957, p. 1391, he was surprised to find no reference to Prof. Balss's important works on the medieval naturalist, Albert the Great. Dr. Isabella Gordon wishes to add that Prof. Balss's scholarly contributions to the history of biology and medicine include the following: "Albertus Magnus als Zoologe" (Munich, 1928); "Albertus Magnus als Biologe: Werk und Ursprung", *Grosse Naturforscher*, 1 (Stuttgart, 1947) and "Aristoteles Biologische Schriften", with Greek text and German translation (Munich, 1943).

Announcements

The following medal awards have been made by the Royal Astronomical Society: *Gold Medal:* Prof. André Danjon, for his contributions to astronomical photometry, to fundamental astronomy and to the design of astronomical instruments; *Eddington Medal:* Dr. H. W. Babcock, for his work on the magnetic fields of early-type stars and of the Sun.

Dr. L. A. Jordan, director of the Research Association of British Colour and Varnish Manufacturers, has been appointed professor of chemistry at the Royal Academy of Arts in succession to Dr. H. J. Plenderleith, keeper of the Research Laboratory, British Museum.

The British Institute of Radiology has made the following awards for 1958: the Barclay Medal to Dr. G. M. Ardran (Nuffield Institute for Medical Research, Oxford); the Röntgen Award to Dr. P. R. J. Burch (Department of Medical Physics, General Infirmary, Leeds); and the Barclay Prize (posthumously) to the late Dr. Trevor Griffiths (Brook Hospital, Shooters Hill Road, London).

The Road Research Laboratory of the Department of Scientific and Industrial Research is again holding open days, this year on May 15 and 16. The Materials and Construction Division and the Colonial Section are at Harmondsworth, Middlesex, and the Traffic and Safety Division at Langley, Buckinghamshire. The Scottish Branch of the Laboratory at Thorntonhall, near Glasgow, will be open to visitors on June 4 and 5.

The third International Seaweed Symposium will be held in Galway during August 13–19. Further information can be obtained from the Secretariat, Third International Seaweed Symposium, University College, Galway, Ireland. Abstracts of communications must reach the Secretariat before April 1.

A symposium on "The Pharmacology of Phenolic Substances" is to be held at Oxford on April 10 and 11 in conjunction with the first annual general meeting of the Plant Phenolics Group. Applications to attend should be made to the secretary, Dr. T. Swain, Low Temperature Research Laboratory, Downing Street, Cambridge.

The Nutrition Society is holding a symposium on "Fish" in the Physiology Lecture Theatre, the Old Medical School, the University of Liverpool, during March 28–29. Further information can be obtained from the hon. programmes secretary of the Nutrition Society, Miss D. F. Hollingsworth, c/o Ministry of Agriculture, Fisheries and Food, Great Westminster House, Horseferry Road, London, S.W.1.

The 1958 International Starch Convention, organized by the German Cereals Research Association, will be held at Detmold, West Germany, during April 22–24. The programme will include papers on research and analysis; starch fractions and derivatives; starch manufacture and practice. Further information can be obtained from Dr. Eric Dux, Sichel Adhesives, Ltd., Riverside Works, 6 Friars Lane, Richmond, Surrey.

A symposium on "Numerical Approximation", sponsored by the Mathematics Research Center, U.S. Army, will be held during April 20–23 at the University of Wisconsin, Madison. The topics of the symposium include linear approximation, interpolation, Tchebycheff and other extremal approximations, expansions and algorithms. Further information can be obtained from Prof. R. E. Langer, Mathematics Research Center, U.S. Army, University of Wisconsin, 1118 W. Johnson Street, Madison 6, Wisconsin.

The spring conference of the X-ray Analysis Group of the Institute of Physics will be held in the College of Science and Technology, Manchester, during April 18–19. There is no specific topic, and papers will be presented on a wide range of subjects, including optical diffraction methods, structural investigations, and X-ray diffraction and X-ray spectrographic techniques. The conference is open to all interested persons on completion of an application form to be obtained from the honorary conference secretary, Dr. C. A. Taylor, Department of Physics, College of Science and Technology, Sackville Street, Manchester 1, to whom all inquiries should be addressed.

The Silver Jubilee Symposium on "The Physical Properties of Polymers" arranged by the Plastics and Polymer Group of the Society of Chemical Industry will be devoted to the fundamental investigation of mechanical and electrical processes in polymers and the physical testing of polymers. It will be held at the William Beveridge Hall, Senate House, University of London, London, W.C.1, during April 15–17. The proceedings will be conducted under the general chairmanship of Mr. C. E. Hollis, chairman of the Group, and Dr. V. E. Yarsley, Mr. C. G. Garton and Dr. L. R. G. Treloar will take the chair for the three daily sessions. Further information can be obtained from the Assistant Secretary (Plastics and Polymer Group), Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

In the review of "Recruitment of Skilled Trades" by Lady Williams published in *Nature* of February 8, p. 373, it is stated in the first paragraph that questionnaires were sent to 9,000 firms. This is incorrect: in fact, 1,000 firms were approached, and 550 replied.

EMPLOYMENT AND WELFARE IN 1956

IN recent years British industry has seen an expanded working population with a high demand for labour and a low rate of unemployment. The annual report of the Ministry of Labour and National Service (H.M.S.O., 6*s*.) shows that this was not the case in 1956.

The total working population (which comprises those in civil employment, in H.M. Forces and the unemployed) increased only slightly, small decreases in the numbers in civil employment and in the Armed Forces being rather more than outweighed by a rise in the number of unemployed persons. There was an increase in the number of workers on short-time and some falling-off in overtime. The number of unfilled vacancies at the end of the year was lower than at the end of 1955. The post-war trend of a falling level of employment in the basic industries and a rising level in the manufacturing industries as a whole was checked.

The total working population rose by 14,000 during the year to a total of 24,087,000 at the end of the year, with a peak in November when a new post-war record total of 24,225,000 was reached. By the end of the year the number of men and women in civil employment had decreased by 64,000 to 22,989,000 and the number of H.M. Forces was 761,000, a reduction of 18,000.

There was some easing in the demand for labour during the year, affecting mainly semi-skilled and unskilled workers. This occurred mostly in the manufacturing industries although there was a small increase in employment in some sections engaged largely on exports and capital goods. Within the basic industries, however, the general decline in man-power was arrested. The number in employment in coal mining increased by more than 3,000 and in transport and communication by 9,000 ; in the gas, electricity and water supply group the labour force remained unchanged ; there was a decrease in mining (other than coal mining) and quarrying, and agriculture again suffered a substantial decline. Other industries which increased their labour force during the year were building and contracting, the distributive trades and the chemicals and allied trades.

The average number of persons registered as unemployed during 1956 was 257,000. Although this represented an increase of 25,000 compared with 1955, it was less than in any other post-war year except 1951.

The rising trend in wages continued, although the rise in prices slowed down until late in the year when a further marked rise occurred. The post-war expansion in industrial production as a whole and in the output per man was halted in 1956, the rates remaining approximately at the 1955-level. A large measure of economy in Government expenditure was part of the Government's general disinflationary policy during 1956. By the careful choice of economy measures the Ministry succeeded in making a substantial contribution to the economies while maintaining its service to industry and the public at a high standard.

The Ministry's employment exchange and appointments services continued their primary purpose of bringing together men and women seeking employment and employers requiring workers ; they also assisted in the supply of labour to the undermanned essential industries. Employers were encouraged to offer ex-regular servicemen resettlement in civil occupations, to accept older and disabled people on their merits and to expand part-time working. In spite of some easing of the shortage of labour, there was still a high average number of unfilled vacancies on the registers of the Ministry. The changes during the year in man-power demands by a number of industries, and especially the redundancies that occurred in the motor-vehicle and other manufacturing industries, made necessary a substantial measure of redeployment of labour ; in this the Ministry, helped by a number of employers who co-operated with employment exchanges by giving early notice of labour redundancies, achieved considerable success. Following a review early in the year, the Notification of Vacancies Orders, 1952, were revoked with effect from May 7, 1956, and at the same time the arrangements for giving preference to certain classes of vacancies were discontinued. Nevertheless, the number of vacancies filled remained high, the total for the year being 2,354,000.

Vocational training was provided by the Ministry for disabled persons, for ex-regular members of H.M. Forces and for other able-bodied men and women. The total numbers of new applicants for training and those completing training during the year were fewer than in 1955. Training was given, in the main, in the Ministry's Government Training Centres.

As in previous years, special services, including industrial rehabilitation and training, were provided to assist disabled persons to obtain employment. Industrial rehabilitation was provided at the Ministry's Industrial Rehabilitation Units, and about 80 per cent of the 7,800 men and women who completed courses either obtained jobs or began courses of training within three months of leaving the units.

Although there were more stoppages of work arising from industrial disputes in 1956, there were considerably fewer working days lost than in 1955 ; the total number of days lost was, in fact, the lowest since 1952. Strikes arising from labour redundancies in the motor-vehicle and ancillary industries were a new feature.

At the end of 1956, there were sixty Wages Councils and five Catering Wages Boards, the same numbers as at the end of 1955 ; one new Council was established and one abolished during the year. Arrears of wages were paid to more than 20,000 workers following action by the Wages Inspectorate.

The increasing awareness in recent years of the need for good human relations in industry was maintained in 1956 ; the incidence of labour redundancies in some parts of the country during the year emphasized both the need for and the value of such relations. The Ministry's Personnel Management Advisory Service continued to meet requests for assistance from particular firms and to co-operate with their organizations in this field ; the value of their work is completely disproportionate to the small numbers employed.

In the international labour and social field the Ministry again made a major contribution to the work of the International Labour Organization.

DEOXYRIBONUCLEIC ACID AND GENETIC MODIFICATION IN DUCKS

IT was natural that the genetic transformation of bacteria effected by the introduction of foreign deoxyribonucleic acid should lead to speculation as to whether the phenomenon could also be induced in higher forms. That similar treatment should be capable not only of altering the racial characteristics of the growing vertebrate but that such changes would also be heritable seemed one of the least likely outcomes of such an experiment.

Recently published reports by Benoit *et al.*[1] state that they have succeeded in changing the characteristics of ducks of one breed by injections of deoxyribonucleic acid from another, and that the modifications continued to be identifiable in the progeny of the treated birds.

Because of the importance that must be attached to such revolutionary claims, and in the absence, as yet, of substantive evidence from repeat experiments, the work of Benoit and his colleagues should be subjected to critical scrutiny.

In the first place it might be suggested that, even with the most meticulous records, proof of somatic transformations of the kind described (size, weight, form of head, bill colour, carriage of body and the general aspect) would be difficult to establish in this species without an appreciation of the range of variability.

This is because there is not only considerable lack of knowledge of the genetics of the duck, but at times the development of breeds depended upon predilection for improvement by the sporadic introduction of other varieties, and this has provided many so-called pure breeds with a cryptic hereditary constitution not always to be expected from their apparent origins.

Preliminary to the experiment the birds were obtained from a reputable breeder and the weekly injections commenced when the Pekin ducklings were 8 days old. Of thirty-six ducklings, twelve (3 males, 9 females) were chosen at random for injection of deoxyribonucleic acid derived from blood and testes of Khaki Campbell drakes, and the remainder kept as controls. Total amounts of deoxyribonucleic acid injected were 5 mgm. per bird for the males and 61 mgm. for the females over a period of 5 weeks and 19 weeks respectively. One male and eight females developed the pronounced somatic modifications described. The females matured normally and laid eggs which, fertilized by treated males, produced twenty-six ducklings, 73 per cent of them having atypically coloured bills, and a good number actually showing other somatic modifications.

Bill colour in the Pekin breed is orange-yellow, and in the Khaki Campbell a greenish black. It may be of significance that a defect of the Pekin listed in British Poultry Standards is "Black marks or spots on the bill".

Although considerable time would appear to have elapsed between the end of the injection period and the discovery of the modifications, the findings, if and when substantiated, would, like the proof of vegetative hybridization, have a tremendous impact on genetic theory and practice.

For the moment it would be as well to agree with Benoit and his colleagues that "Aujourd'hui, notre meilleure conclusion sera que nous n'avons aucune conclusion à vous présenter", and await the repetition and extension of this work by them and others who will, no doubt, be stimulated by the reports.

ALAN W. GREENWOOD

UNION OBSERVATORY, JOHANNESBURG

THE annual report of the Union Observatory, Johannesburg, for 1956 (which appeared in October 1957) follows the usual lines, and it will be sufficient to refer to the main events during the period under consideration. The 26½-in. refractor was used with the interferometer by Dr. W. S. Finsen for the measurement of double stars and the discovery of new ones on 135 nights, and on 68 nights for colour photography of Mars. In addition, Mr. J. Churms and Dr. W. H. van den Bos used it on 68 nights for the measurement of known double stars. Messrs. J. A. Bruwer and Churms, with a number of amateur astronomers who are members of the Transvaal Branch of the Astronomical Society of South Africa, used the 9-in. refractor on 179 nights for observations of planets, variable stars, etc., the amateurs rendering valuable assistance to the staff on visiting evenings and in many other ways. The results of the occultation observations were communicated to H.M. Nautical Almanac Office.

The Franklin-Adams telescope at the Hartbeestport Annexe obtained 178 plates for minor planets and 23 plates for comets, and the resulting positions were regularly communicated to the respective central bureaux of the International Astronomical Union at Cincinnati and Copenhagen. Dr. Finsen devoted much of his leisure time to the preparation of composite enlargements from the colour films of Mars obtained during the favourable opposition of 1954 and 1956. The card catalogue of double stars south of − 19° dec. has been kept up to date, and information has been supplied to other astronomers on request.

With the 3-in. refractor sunspot counts were obtained on 281 days, the other days being overcast or unsuitable for reliable counts. The results have been regularly communicated to the Telecommunication Research Laboratory of the South African Council for Scientific and Industrial Research, the Magnetic Observatory at Hermanus and the Receiving

Station of the South African Broadcasting Corporation at Panorama.

Under "Time Services", reference is made to improvements to the control circuits of the Diesel generator and to the vibrator power supply units so that the quartz clock installation is now practically independent of mains interruptions. A new frequency divider employing cold-cathode valves was built, and the stability of other frequency dividers improved. The performance of the ring crystal over short periods was rather more erratic than had been expected, and from October onwards all the time and frequency equipment has been controlled by oscillator 4*A* while further tests are being made. A twelve-channel frequency recorder, designed and built by the British Post Office, was delivered in June, and this recorder has been of very great value in keeping a continuous check on the performance of all parts of the time installation. A new cathode-ray oscilloscope comparison unit was built and this measures the reception time of time signals in terms of local time to one ten-thousandth of a second.

Under "Miscellaneous Public Services" reference is made to the Wiechert horizontal seismograph which was in operation throughout the year; local earth tremors and records of ten distant earthquakes; and records of rain have been sent monthly to the Bernard Price Institute for inclusion in its monthly *Seismological Bulletin*. Reference is also made to the installation of a synchronous motor drive on the twin telescope, and to the transfer of the Leyden Southern Station from Johannesburg to Hartbeestport.

FEDERAL RESEARCH AND DEVELOPMENT EXPENDITURE IN THE UNITED STATES*

THE National Science Foundation has issued an analysis of the Federal Research and Development Budget for the fiscal years 1956, 1957 and 1958, in which latter year twenty-three agencies of the Federal Government allocated 3,400 million dollars for scientific research and development, an increase of nearly one-fourth on 1956. Actual expenditure increased from about 2,500 million dollars to almost 3,000 million dollars in 1957 and is expected to reach 3,300 million dollars in 1958. From 85 to 90 per cent of these funds are for the conduct of research and development, including the pay and allowances of personnel, actual expenditure increasing by 14 per cent in 1957, and it is expected to increase by 10 per cent in 1958 to 2,900 million dollars. Some 10–15 per cent of the total is on the expansion of plant and equipment, including the acquisition of land, and expenditure for these purposes increased from just over 200 million dollars in 1956 to an estimated 437 million dollars in 1958, mainly on plant or facilities for defence.

Of the twenty-three agencies, the Department of Defense and the Atomic Energy Commission together account for 88, 85 and 82 per cent of the total funds in 1956, 1957 and 1958, respectively, about 45 per cent of the Defense Department funds being administered by the Air Force. For 1957 and 1958, 672 million dollars were allocated by the Atomic Energy Commission, compared with 2,166 million and 2,111 million dollars, respectively, by the Defense Department. Allocations of the Department of Health, Education and Welfare for scientific research and development increased from 89 million dollars in 1956 to 200 million in 1958, and of the 182 million allocated in 1957, 175 million were primarily by the National Institutes of Health for research on the diagnosis, cause and treatment of disease. The Department of Agriculture increased its allocation from 84 million dollars in 1956 to 108 million in 1957 and 132 million dollars in 1958; for the National Advisory Committee for Aeronautics, the corresponding figures are 66 million, 80 million and 94 million dollars; for the Department of the Interior, 38 million, 47 million and 53 million dollars; for the National Science Foundation, 17 million, 48 million and 47 million dollars; and for the Department of Commerce, 18 million, 25 million and 33 million dollars, respectively, the decrease for 1958 in the allocation by the National Science Foundation being because of the International Geophysical Year.

Of the 2,231 million dollars expended on the conduct of research and development in 1956, 1,388 million was on development and 844 million on research, of which 157 million was on basic research. The corresponding figures for 1957 are estimated as 2,635 million dollars, 1,671 million, 964 million and 218 million, respectively, and for 1958, 2,782 million dollars, 1761 million, 1,021 million and 233 million, respectively. Of the expenditure on research in 1956, 198 million dollars was on the biological sciences, 616 million dollars on the physical sciences, and 30 million on the social sciences; in basic research, the corresponding distribution was 50 million, 104 million and 3 million dollars. For 1957 the corresponding distribution in total research is estimated as 281 million, 627 million and 35 million, and in basic research 70 million, 143 million and 4 million dollars; and for 1958 in total research, 317 million, 637 million and 48 million, and in basic research, 83 million, 143 million and 6 million dollars. Subdivided again, total research expenditure on the biological sciences in 1956 included 99 million dollars on medical sciences and 44 million on agricultural sciences; for 1957 the corresponding estimates are 158 million and 53 million dollars, and for 1958, 177 million and 59 million dollars. That on the physical sciences in 1956 included 6 million dollars on the mathematical sciences and 456 million dollars on the engineering sciences; corresponding estimates for 1957 are 7 million and 435 million dollars, respectively.

Of the 2,830 million dollars allocated for the conduct of research and development by the Federal Government in 1957, 48 per cent was spent on work performed by Government agencies, including pay and allowances of military personnel engaged in such work. Of the remainder, 35 per cent went to work carried out by profit organizations, about one-fourth of this going to research institutions administered by such organizations, 14 per cent went to educational institutions and the remaining 3 per cent to other institutions, including non-profit research institutions, foundations and hospitals.

---

* National Science Foundation. Federal Funds for Science 6: The Federal Research and Development Budget, Fiscal Years 1956, 1957 and 1958. Pp. iii+60. (Washington, D.C.: Government Printing Office, 1957.) 40 cents.

Since the 1948 low level of just over 850 million dollars, Federal Government expenditure on scientific research and development has risen steadily, except in 1954, to 2,800 million dollars in 1957, or just over 4 per cent of the total budget expenditure compared with just over 2 per cent, and it is estimated that expenditure on basic research has increased by more than 85 per cent since 1952, although still amounting to only 8 per cent of the total funds for the conduct of research and development, exclusive of the pay and allowances of military personnel. In the same period, allocations for research in the biological sciences also increased by more than 83 per cent. It is estimated that the increases have been greater than the rate of increase in costs for salaries and equipment for scientific work and that accordingly when due account is taken of such rising costs the long-term trend still reflects a steady increase in the provision of Government funds for scientific research and development. Besides the statistical tables, the report includes technical notes on the limitations of the data and definitions and a list of research centres.

PHOTOPERIODISM IN PLANTS AND ANIMALS

AN international symposium on "Photoperiodism in Plants and Animals", sponsored by the Photobiology Committee of the National Research Council of the United States, was held at Gatlinburg, Tennessee, during October 29–November 2.

In an introductory session the reversible photochemical properties of certain dyes were described by Dr. G. Oster (Polytechnic Institute of Brooklyn) and problems of energy transfer in photochemical systems were discussed by Dr. Gordon Tollin (University of California, Berkeley). Dr. Stacey French (Carnegie Institution, Stanford) discussed the difficulties of determining action and absorption spectra in living systems.

One session was devoted to the various photoperiodic effects observed in growth and dormancy of plants. Dr. J. L. Liverman (Texas Agricultural Experiment Station) and Dr. W. H. Klein (Smithsonian Institution, Washington) dealt with the interaction between red light and various other factors in the growth of bean leaf disks, and the uncoiling of the bean epicotyl hook, respectively. Both speakers reported that the effects of indole-acetic acid, kinetin, gibberellic acid and the cobaltous ion seem to be independent of those of red light. There appears, however, to be an interaction between adenine and red light in the growth of bean leaf disks. Dr. E. H. Toole (U.S. Dept. of Agriculture, Beltsville) described the responses of various light-sensitive seeds and Dr. P. F. Wareing (University of Manchester) dealt with the photoperiodic control of germination, with special reference to the action of various spectral regions and the possible role of growth inhibitors. Dr. R. J. Downs (U.S. Dept. of Agriculture, Beltsville) discussed the interaction between red and infra-red radiation in relation to various aspects of vegetative growth. The effects of red irradiation on the activity of indole-acetic acid oxidase were shown by Dr. A. W. Galston (Yale University) to be due to the formation of an inhibitor of this enzyme by red light.

Dr. R. van den Veen (Philips' Research Laboratories, Eindhoven) described experiments which involved growing various species entirely under high-intensity monochromatic light. It was found that there are marked differences between species with respect to growth responses, under the various spectral regions. There are complex interactions between blue and red, especially in relation to the control of flowering. Prof. E. C. Wassink (Agricultural University, Wageningen) also described the responses of various species grown under high-intensity radiation in narrow spectral regions.

Two sessions were devoted to the photoperiodic control of flowering. Dr. Ralph Wetmore (Harvard University) and Dr. E. M. Gifford (University of California, Davis) described the structural changes occurring in shoot-apices of *Xanthium* and other species in the transition from the vegetative to the flowering condition. The interaction of red and far-red radiation in the flowering of various species, including *Hyoscyamus*, was dealt with by Dr. H. A. Borthwick (U.S. Dept. of Agriculture, Beltsville). Dr. Roy Sachs (University of California, Los Angeles) discussed the implications of 'long-short' day plants, such as *Cestrum nocturnum*, for general theories of photoperiodism.

Dr. A. Lang (University of California, Los Angeles) read a paper dealing with the general problem of the role of auxin and gibberellins in flowering. Auxin tends to be inhibitory of flowering in short-day plants and promotive in long-day plants, but it appears only to modify the responses. Both gibberellic acid and gibberellin-like fractions from *Cucurbita* endosperm are capable of inducing flowering in some long-day plants, but cannot replace photo-induction in short-day plants. Photo-induction in long-day plants appears to involve reactions other than gibberellin-controlled processes, which may be concerned primarily with stem elongation. The interactions between gibberellic acid and photoperiodic responses were discussed by Prof. Fausto Lona (University of Parma) for a wide variety of species.

The effects of certain synthetic hormones on flowering of *Xanthium* were described by Dr. A. Naylor (Duke University), and Dr. F. Salisbury (Colorado State University) described the interaction between various applied growth substances and the critical dark period in *Xanthium*. Dr. W. Jacobs (Princeton University) discussed the relations between auxin, day-length and compensatory growth in *Coleus*.

In a general paper on the nature of the photo-inductive processes in photoperiodism, Dr. James Bonner (California Institute of Technology) outlined the present state of knowledge of the various partial processes involved, and discussed the possible reasons why the 'flower-hormone' has not yet been isolated. Dr. R. B. Withrow (Smithsonian Institution, Washington) gave a general account of the kinetic aspects of the photoreactions. He distinguished between 'graded' responses (for example, of light-sensitive seeds) and 'threshold' responses (for example, photoperiodic phenomena). Dr. S. B. Hendricks (U.S. Dept. of Agriculture, Beltsville) also dealt with kinetic aspects of the photo-reactions of photoperiodism and showed how certain kinetic parameters of the photo-receptor system can be derived. He also described a second photo-receptor system which appears to be involved in anthocyanin synthesis.

A series of papers dealt with photoperiodism in animals. Dr. A. D. Lees (A.R.C. Unit of Insect Physiology, Cambridge) reviewed the phenomena of photoperiodism in insects and mites, particularly in relation to the onset of diapause. Photoperiodic responses appear to be widespread in Lepidoptera. Dr. C. E. Jenner (University of North Carolina) dealt with photoperiodism in an aquatic midge, the larval stage of which is found in the 'pitchers' of pitcher plants. Reproduction in certain snails and freshwater shrimps appears to require long-day conditions. Photoperiodism is also of importance in many marine invertebrates, including crustaceans, molluscs and echinoderms, as was shown by Dr. A. C. Giese (Stanford University).

The general problem of the seasonal control of reproductive cycles in vertebrates was discussed by Dr. W. S. Bullough (University of London), who emphasized that photoperiodism constitutes only one aspect of a highly complex system. In vertebrates, photoperiodic perception appears generally to be mediated through the eyes. In carp and related fishes, courtship and breeding appear to be induced by increasing day-length in the spring, as shown by Dr. R. W. Harrington (Florida State Board of Health). Photoperiodic effects have also been reported in certain reptiles, including the pond-turtle, the American chameleon and certain lizards. Dr. G. A. Bartholomew (University of California, Los Angeles) emphasized, however, that in the latter the importance of photoperiodic responses is probably over-ridden by behavioural patterns in relation to diurnal temperature changes.

Endogenous rhythms in the ovulation cycle of hens were described by Dr. R. M. Fraps (U.S. Dept. of Agriculture, Beltsville). Dr. D. S. Farner (State College of Washington) showed that in certain birds day-length controls a variety of physiological responses including the male gonadal cycle, fat metabolism, vernal migration and probably moulting. In the white-crowned sparrow the most effective spectral region controlling development of the testes appears to be in the red. Dr. A. Wolfson (North Western University, Evanston) described photoperiodic control of migration in the juncos of Alberta, in which fat deposition appears to be an important factor. The responses in these birds appear to be determined by the duration of the daily dark period. Photo-periodic responses in other bird species were described by W. L. Engels (University of North Carolina), Dr. C. M. Kirkpatrick (Purdue University) and Dr. W. O. Wilson (University of California, Davis).

A further series of papers was devoted to endogenous rhythms in plants and animals. Dr. E. Bünning (University of Tübingen) gave a general account of endogenous rhythms, and discussed some general properties of the 'timing mechanism' in such rhythms. Dr. K. C. Hamner (University of California, Los Angeles) described the results of experiments with 'Biloxi' soybean, in which it was found that flowering occurred with cycle-lengths of 24 hours or of multiples thereof, whereas with cycles of intermediate duration flowering was partially or completely inhibited. These results are held to indicate an endogenous rhythm in photoperiodic sensitivity. Dr. F. W. Went (California Institute of Technology) showed that certain species, notably the tomato, made favourable growth on 24-hour cycles but showed reduced growth and other adverse symptoms on other lengths of cycle. These effects are exhibited in both photoperiodic and thermoperiodic phenomena.

Dr. C. S. Pittendrigh (Princeton University) discussed the possible nature of the clock mechanism in endogenous rhythms and postulated that two types of 'oscillator' may be involved, namely: (1) a primary light-sensitive oscillator which is temperature-independent, and the phase of which is determined by external light conditions; (2) a temperature-sensitive oscillator which can 'entrain' oscillator (1). Endogenous rhythms of activity in the hamster, and of bioluminescence in *Gonyaulax polyedra*, were described by Dr. K. S. Rawson (University of Wisconsin) and Dr. J. W. Hastings (Northwestern University) respectively.

Three evening sessions were devoted to sixteen short papers, including seven dealing with interactions between gibberellic acid and various light-controlled processes.

This highly successful meeting is believed to have constituted the first international symposium devoted specifically to photoperiodism in plants and animals. Biologists working in this field are indebted to the Photobiology Committee for organizing the meeting and especially to Dr. R. B. Withrow and Dr. N. E. Tolbert, chairman and secretary of the Committee respectively.

P. F. WAREING

FARMING HISTORY

THE joint annual conference of the British Agricultural History Society and the Association of Agriculture was held on December 7 at the Institute of Education, University of London. Three papers were read. Mr. George Ordish discussed the "History of Crop Pests, and the Measures taken to overcome them". After lunch, two papers on horticultural history were presented. Dr. L. G. Bennett, Department of Agricultural Economics, University of Reading, spoke on the "History of the Development of Market Gardening", and Mr. Eric Hobbis, of Long Ashton Research Station, University of Bristol, on the "History of Soft Fruit Growing".

Pests and diseases of plants are as ancient as the cultivation of crops for food, and the uncultivated flora that flourished before man was probably also afflicted. Mr. Ordish showed by exhaustive references to Pliny that pests and diseases were well known in classical times. Apples and pears were affected, and the olive fly was prevalent. It is still a trouble. There were cereal pests, wireworm and the cabbage flea beetle, but there was no phylloxera, nor the two mildews that were introduced from America much later.

Methods of protection were then of four kinds: religious, superstitious, mechanical and chemical. Though some of the first two were peculiar, it is not advisable to dismiss them out of hand. The superstition of yesterday often turns out to be the science of to-day. Achilles barley, presumably an immune variety, was recommended by Pliny when rust was very bad. Treating with burnt ash, steeping seed in wine and the dregs from the oil presses were other preventive measures. Greasebands were fixed on the vines, and indeed are still used in Turkey.

No doubt the prevalence of pests and diseases, and the lack of knowledge of how to destroy or cure them, was a factor, among others, that kept yields at a low level for a thousand years or more.

Mr. Ordish proceeded to a discussion of the work of the sixteenth- and seventeenth-century botanists, more particularly that of Thomas Mouffett and Topsell. He said that Worlidge in 1669 had set out a method of dealing with hop mildew that would effectively control one type. The belief in the spontaneous generation of bugs, lice and other insects "out of corruption" was widely held by writers of that date, and was not disposed of until later scientists had shown that these pests were born out of eggs. New material had become available in the eighteenth century, and Richard Weston and others suggested the use of tobacco dust, spraying with a nicotine solution, and fumigating with tobacco smoke. Steeps of brine and urine had continued to be used to control cereal rusts, but there was some dispute about their efficacy. Some remarkable randomized experiments were made by Tilly in France about 1750 to test controls.

Necessarily, Mr. Ordish's paper was an outline of a vast subject, and, as was then said, it is to be hoped that he will make and publish an exhaustive study of the subject. The only existing treatise is a very brief American publication.

Dr. Bennett traced the development of commercial market gardening from the sixteenth to the nineteenth century. Before 1500 he thinks there was little. The use of vegetables is said to have declined between the eleventh and the sixteenth centuries, and to have been revived only with the new methods of cultivation introduced to Great Britain by French and Dutch refugees from religious persecution. It is, however, a little difficult to accept this conclusion, because, if it is true, some other food must have taken the place of the onion, garlic, leek, cabbage, peas and beans, worts and other herbs that all went into the pottage commonly consumed by the generality of the people. Be that as it may, Dr. Bennett made it quite clear that there was a great extension of market gardening in the sixteenth century. The refugees settled in the Sandwich area and elsewhere in Kent, around Norwich, and eventually in the immediate environs of London, where a part of Covent Garden was set aside for a vegetable and fruit market held three days a week. The Worshipful Company of Gardeners was organized by the growers to exercise control over malpractices and to look after their interests. From this time market gardening increased in importance, especially in the nineteenth century, when the growth of population in large aggregations, some rise in the standard of living, and changes in dietetic taste led to an immensely increased demand for fruit and vegetables.

Mr. Hobbis indicated no such decline in the use of soft fruits during the Middle Ages as there may have been in vegetables and herbs. Strawberries, raspberries and gooseberries were known to our remote ancestors, but the raspberries were not very well liked until the sixteenth century. They were thought sour. Red currants were then regarded as a small kind of red gooseberry. From such small beginnings a very large soft-fruit growing industry had developed by the nineteenth century, and it expanded widely during that century, though it had not then spread to the eastern counties. The two wars had a bad effect, but the soft-fruit growing industry under modern influences—factory jam-making, canning, deep freezing, and so on—is reviving, while the results of research are providing growers with advantages unknown to their predecessors.

Such subjects are not simple, and it is difficult to make a summary of all the important points raised in these two lectures and the discussion that followed them. All three lecturers demonstrated that there are large areas in the history of agriculture and horticulture that still require exploration.

The headquarters of the British Agricultural History Society have now been moved to the Department of Agriculture, Parks Road, Oxford, and anyone interested should make inquiries of the Hon. Secretary at that address. G. E. Fussell

GELATINE AND GLUE

At the fourteenth meeting of the Research Panel of the British Gelatine and Glue Research Association, held on December 12, Dr. S. M. Partridge (Low Temperature Research Station) took the chair for the morning session and Mr. S. G. Hudson (Richard Hodgson and Sons, Ltd.) for the afternoon session. The first paper was by Mr. G. Russell (Ilford, Ltd.) with the title "Chemically Distinct Major Components of Gelatin"[1]. He outlined previous views on the level of impurities (other than inorganic ions) in high-grade gelatines. Methods such as heat coagulation, or adsorption on charcoal, suggest a protein impurity-level of not more than 0·5 per cent. In an attempt to separate these impurities from gelatin, experiments were carried out, in which chromatographic column technique was applied, using a finely divided form of the resin, '*I.R.C.50*'. Elution was effected with a buffer previously used for equilibrating the column, so that the whole operation took place at the same *p*H. Protein in the fractions was estimated, after hydrolysis, by reaction with ninhydrin.

Whereas at *p*H 6 the whole of the gelatin sample is eluted, giving a curve of concentration against eluant volume with a twin peak, at *p*H 5·5 only a portion of the sample (15 per cent) is eluted, the remainder (85 per cent) being firmly adsorbed on the resin. The latter fraction can be removed by raising the *p*H. Paper chromatograms show the smaller component to have a higher tyrosine content than ordinary gelatin, no detectable hydroxyproline, and other characteristics giving it an amino-acid composition broadly similar to the serum albumins. The major component is similar to gelatin. Quantitative results for tyrosine, using ultra-violet absorption, show the major component to have zero or only a trace of tyrosine, whereas the minor component has about 3 per cent. Assuming the tyrosine to be entirely present in the minor component, the content of this component in a series of gelatins ranges from 10 to 20 per cent. Mr. Russell considered some of the implications of his work, and a keen discussion showed the interest aroused. Dr. G. R. Tristram (University of St. Andrews) reported a separation, presumably of the same two components, on a modified cellulose column. It was clear from many comments that the future course of research on gelatin may be very much modified by Mr. Russell's work.

The second paper, "Some Aspects of Connective Tissue in Relation to Age", by Dr. R. Consden and Dr. P. C. Brown, of the Special Unit for Juvenile Rheumatism of the Canadian Red Cross Memorial Hospital, Maidenhead, discussed the chemical make-up of connective tissue. Recent work, both on collagen and on the polysaccharides of connective tissue, has revealed the complexity of the problems requiring solution. Whereas certain polysaccharides are readily removed by very mild processes, others are so firmly held that their association with the collagen must be very intimate. This applies in particular to the neutral polysaccharides. The course of fibrogenesis was outlined, and the contrast between young tissues, whether in young animals or in freshly formed tissue in wounds, and mature tissues was emphasized. The inertness of collagenous tissue was illustrated from Glynn's experiments on embedding dead tissue in living animals to study their rate of destruction. Collagen appears to persist indefinitely, whereas liver or muscle is metabolized fairly quickly. If, however, the collagen is heat-shrunk, it then is attacked fairly rapidly. The collagen of the uterus, which Harkness has studied, shows unusual features in being able to undergo rapid growth during pregnancy and rapid reabsorption at parturition. The increased stability of collagen with age, which can be demonstrated also as an increase in the force to inhibit contraction under thermal shrinkage conditions, is related to greater orientation and crystallinity. Keech has shown that a greater resistance to collagenase develops. A survey of human collagenous tissue shows that there is a significant increase of shrinkage temperature with age, and older tissue is more resistant than young to the action of hydrogen-bond breaking reagents. Uterine collagen has a significantly lower shrinkage temperature than adult collagen from elsewhere.

The third paper, "An Approach to the Non-Gelatin Constituents of Gelatines and Glues", was given by Mr. A. A. Leach, of the Association staff. Using bone glue as the starting material, it is possible to separate from it a component, present in substantial amount, which partially coagulates at about *p*H 4 and can be centrifuged off. This component is made up of a complex of lipid, polysaccharide, non-collagenous protein and a gelatin-like substance. The lipid is derived from the bone fat, and the analytical evidence suggests that the polysaccharide and non-collagen protein have their origin in the 'osseomucoid' isolated from compact bone and analysed by Eastoe and Eastoe. It is not certain to what extent the links between gelatin and the complex are formed during processing in bone glue manufacture, or are already present in the tissue. Attempts to separate the gelatin from the complex, using either heat coagulation of the second protein or differential trypsin attack on the gelatin, although partially successful, were not quantitative.

Bone glue from which the complex had been removed was fractionated by the alcohol method of Stainsby. It was then shown that the bulk of the non-gelatin components, other than the complex, remain in solution at the end of fractionation. They include substantial amounts of polysaccharide. It must be presumed that a further separation of the 'gelatin-like' fractions into the two components of Russell above would still be possible using the resin column technique.

INTESTINAL biopsy has proved of little value in the diagnosis of idiopathic steatorrhœa. Paulley[1] has described changes in the mucosa which cannot be regarded as specific.

The object of this communication is to report a hitherto undescribed association between a lipoprotein pigment in intestinal smooth muscle and steatorrhœa.

The material was obtained from necropsies on a variety of intestinal disorders (Table 1). Four of the cases of steatorrhœa were diagnosed in life on the basis of high content of fat in the stool, high proportion of unsplit fat, low serum calcium-level and megaloblastic anæmia. The percentage of fat absorbed was found to be abnormally low in three cases, using a 'fat balance' test. In two other cases, in which pigment was found, the diagnosis of steatorrhœa was not confirmed during life. In one of these cases a diagnosis of Whipple's disease[2] rested upon histological findings alone.

Pieces for histogical examination were fixed in 10 per cent formal–saline or in corrosive formal. Paraffin sections were prepared and stained by Harris's hæmatoxylin and eosin; preliminary treatment with Lugol's iodine and sodium thiosulphate was given to those fixed in corrosive formal.

Those sections which showed pigment in the smooth muscle of the small intestine were stained by histochemical methods. Sections were stained for protein by the tetrazo method of Danielli following the technique described by Dixon[3]. This method detects tyrosine, tryptophan and histidine groups in the protein molecule. The Feulgen method[4] for deoxyribonucleic acid and pyronin G[5] for ribonucleic acid were applied. The periodic acid–Schiff method[6] and the permanganate–paraldehyde–fuchsin method[7] were used for detecting carbohydrates. Sudan black was employed for detecting lipids.

The presence of an unusual pigment was suggested in the case of Whipple's disease by a brown coloration

Table 1. ILLUSTRATING THE TYPE OF CASE INVESTIGATED AND THE OCCURRENCE OF PIGMENT

of the muscular layers visible to the naked eye. In the five cases of steatorrhœa a delicate grey brown pigment was found in the hæmatoxylin and eosin preparations almost filling the cytoplasm of the smooth muscle cells of both the longitudinal and circular layers (Fig. 1). A remarkable feature was the total absence of pigment from the cells of the muscularis mucosæ. In the case in which stomach was examined and in the two cases in which colon was examined pigment was found in the same layers. Pigment was not found in any of the other examples of intestinal disease which were examined.

The histochemical reactions of the pigment were, in every case, the same. It stained bright red with the tetrazo method, purple with permanganate–paraldehyde–fuchsin and black with Sudan black. The findings suggested that it is a lipoprotein. No reaction was obtained with the other methods employed.

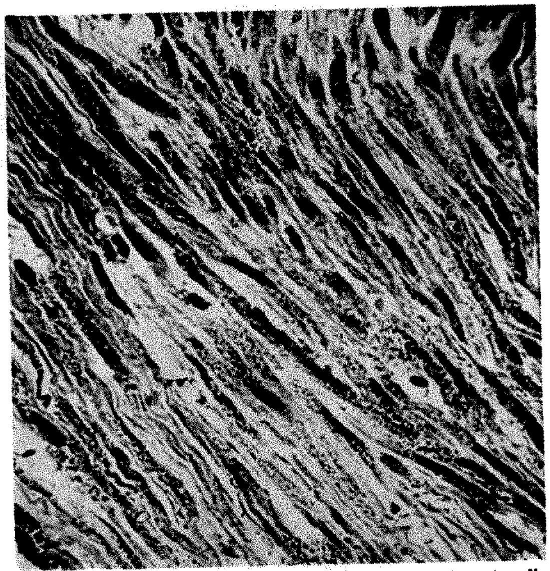

Fig. 1. Pigment in smooth muscle of jejunum. (Hæmatoxylin and eosin. × 450)

The presence of smooth-muscle pigment in cases of idiopathic steatorrhœa and Whipple's disease is of interest, first because of its diagnostic value and secondly because it may provide a clue to the etiology.

Paulley[1] saw pigmentation in the muscle coat in one case of idiopathic steatorrhœa, but did not consider it to be of any significance. Laparotomy was done in this case for subacute intestinal obstruction and consequently the full thickness of the gut was available for histological examination. He did not remark upon such pigmentation in his other cases. Further examples of idiopathic steatorrhœa need to be examined before the association of muscle pigment and the disease can be clearly established. Such an association is of little diagnostic value except in those cases in which the full thickness of gut-wall can be obtained. Since the pigment was not seen in the muscularis mucosæ, intestinal biopsy by Wood's tube[8] would be of little value since mucosa and muscularis only can be taken.

The histochemical properties of this pigment closely resemble those of lipofuscin (wear and tear pigment) commonly seen in cardiac muscle and in the olivary and dentate neurones. The pigment in the latter differs only in that it stains with paraldehyde-fuchsin without previous oxidation with permanganate. Scott and Clayton[9] consider that this property indicates the presence of 'highly sulphated mucopolysaccharides'. Staining with paraldehyde-fuchsin following permanganate oxidation was a feature of the pigment in the small gut and of brown atrophy pigment in the heart. This property, when the periodic acid–Schiff test is negative, suggests the presence of either cystine or highly sulphated mucopolysaccharides.

The origin of lipofuscin is debatable[10]. Marinesco[11] considers that it may arise from mitochondrial remnants. This would only seem likely if the ribonucleic acid content of mitochondria had previously been destroyed, since lipofuscin does not stain with pyronin *G*, which is considered to be a specific stain for this nucleic acid[12].

It is tempting to suppose a mitochondrial origin for the pigment in the intestinal smooth muscle in cases of steatorrhœa. Mitochondrial surfaces are sites of enzymic activity[13] which may be concerned with the absorption of fat through the intestinal wall. This hypothesis would seem more probable if the pigment was situated in the mucosa rather than in the muscle. However, the mechanism of fat absorption is still obscure[14] and such a hypothesis is worthy of consideration.

We are grateful to Dr. A. M. Barrett for his encouragement and permission to use the necropsy reports and material.

ENZYMIC SYNTHESIS OF COENZYME I IN RELATION TO CHEMICAL CONTROL OF CELL GROWTH

By Prof. R. K. MORTON

Department of Agricultural Chemistry, Waite Agricultural Research Institute, University of Adelaide

IT is generally accepted that the cell nucleus carries the genetic determinants of cell behaviour. It must therefore exercise control of cell division, growth and differentiation, probably by means of a compound, or compounds, synthesized exclusively in the nucleus but essential for cytoplasmic reactions. Such a compound is coenzyme I (nicotinamide adenine dinucleotide, or so-called 'diphosphopyridine nucleotide'). It is required for more enzymic reactions than any other known coenzyme and is as essential for the aerobic and anaerobic mechanism for provision of energy for the cell as adenosine triphosphate.

In animal cells, coenzyme I is synthesized from nicotinamide, according to the following reactions which are catalysed by the enzymes nicotinamide mononucleotide–pyrophosphorylase (equation 1)[1], and coenzyme I–diphosphopyridine nucleotide–pyrophosphorylase (equation 2)[2,3].

$$1.\ \text{Nicotinamide} + \begin{array}{c}\text{5-phosphoribo-1-}\\ \text{pyrophosphate}\end{array} \rightleftharpoons \begin{array}{c}\text{nicotinamide}\\ \text{mononucleotide}\end{array} + \begin{array}{c}\text{inorganic}\\ \text{pyrophos-}\\ \text{phate}\end{array}$$

$$2.\ \begin{array}{c}\text{Nicotinamide}\\ \text{mononucleotide}\end{array} + \begin{array}{c}\text{adenosine}\\ \text{triphosphate}\end{array} \rightleftharpoons \begin{array}{c}\text{nicotinamide}\\ \text{adenine}\\ \text{dinucleotide}\end{array} + \begin{array}{c}\text{inorganic}\\ \text{pyrophos-}\\ \text{phate}\end{array}$$

By a tissue-fractionation method, Hogeboom and Schneider[4] showed that coenzyme I–pyrophosphorylase was mostly localized in the cell nucleus in mouse liver. Branster and Morton[5] confirmed and extended this important finding by showing that the activity per nucleus is the same in isolated nuclei as in isolated intact liver cells[6,7]. The enzyme is also found in the nucleus in normal and tumour cells from mouse mammary gland[8] and in avian erythrocytes[9]. As yet it is the only enzyme known to occur exclusively in the cell nucleus.

The coenzyme I produced in the nucleus, where it may occur in relatively high concentration[10], is supplied to the cytoplasm wherein it participates in the reactions catalysed by numerous dehydrogenases. However, it also may be degraded relatively rapidly by cytoplasmic nucleosidases[11] and pyrophosphatases[12]. Provided that the dietary vitamin (nicotinamide or nicotinic acid) intake is adequate, therefore, the amount of coenzyme I available for cytoplasmic dehydrogenation reactions depends on the relative rates of the synthetic reactions (equations 1 and 2) as compared with the degradative reactions. Synthesis of new compounds by exchange reactions *in vivo*[13] and studies with intact whole cells[5] established that degradation *in vivo* is rapid and thus there must be a relatively high turnover-rate of coenzyme I in the cell.

Branster and Morton[8] therefore tested the hypothesis that a sufficient change in the rate of synthesis of coenzyme I by the nucleus would modify normal cell division and differentiation and thus lead to malignant growth. It was assumed that the activity of the coenzyme I–pyrophosphorylase (equation 2) would limit synthesis. In comparative studies, a unit of activity was taken as the synthesis from nicotinamide mononucleotide of 1 μmole of coenzyme I per hr. per 10^9 nuclei at 38°. With C_3H mice they found that the activity of spontaneous mammary gland carcinoma (2·8 units) was about 20 per cent of that of normal lactating mammary gland (13 units)[8]. With strain *A* mice, the activity of hepatoma (9 units) induced by feeding aminoazotoluene was about 20 per cent of that of normal liver (42 units) of control animals[5]. Very low rates of synthesis were also found[5] with Ehrlich ascite cells (2 units) from mice, and with post-operative human tumours. In the latter cases, however, no suitable normal tissues were available for comparison.

Branster and Morton[8] also found that the activity of normal liver of C_3H mice markedly increases during growth, being 2 units for fœtal, 12 units for young (7 and 17 days old) and 42 units for adult mice. Thus both tumour cells, and rapidly growing fœtal cells, have low activities as compared with suitable normal cells. On the basis of the rate of synthesis of coenzyme I per nucleus, therefore, the tumour cell represents a change from an adult-type to an embryonic-type of cell, and this is consistent with the general morphological and behavioural characteristics of tumour cells.

A low content of coenzyme I (and of coenzyme II) in tumour as compared with normal tissue has been established[14,15]. When expressed as μgm. of coenzyme per gm. of tissue, dye-induced hepatomas contain 48 per cent of the total coenzyme I and 14 per cent of the total coenzyme II of normal rat liver[15]. Hepatoma and normal rat liver contain the same amount of deoxyribonucleic acid phosphorus per nucleus[16] but 546 and 249 μgm. of deoxyribonucleic acid phosphorus per gm. of tissue, respectively[17]. Thus there are about 2·2 times as many nuclei per gm. of tissue in hepatoma as compared with normal liver. Expressed on the preferable basis of amount per nucleus[8,18,19], therefore, the results of Glock and McLean[15] indicate that hepatomas contain about 20 per cent of the coenzyme I of normal rat liver. Thus there is good agreement between the relative amounts of coenzyme I and the relative coenzyme I–pyrophosphorylase activities in hepatoma and normal liver. Also in agreement with the finding of a similar amount of coenzyme I in the two tissues[15], there was no significant difference between the coenzyme I–pyrophosphorylase activity of liver in hepatoma-bearing mice and in the controls[5]. The low content of coenzymes I and II cannot be attributed to increased cytoplasmic degradation which is no greater[20], and frequently less[5], than that of comparable normal tissues. A decreased activity of nicotinamide mononucleotide–pyrophosphorylase (equation 1) may occur in tumours and thus potentiate the effect of a decreased activity of coenzyme I–pyrophosphorylase. It appears, however, that this latter effect largely accounts for the low content of coenzyme I in tumours as compared with normal tissues. A low coenzyme I–pyrophosphorylase activity would also account for the synthesis of only 25 per cent of the coenzyme I in regenerating (48 hr.), as compared with normal, mouse liver in animals injected with large amounts of nicotinamide[21].

Weinhouse and his colleagues found that coenzyme I is a limiting factor in the respiration of homogenates and isolated mitochondria from tumours. This 'coenzyme I-effect'[22] would be expected from the low content of coenzyme I in tumour mitochondria[15], but it also may be due to the rapid dissociation of the so-called 'bound' coenzyme I from the tumour mitochondria and consequent rapid hydrolysis of the coenzyme[23]. Structural imperfection of the tumour mitochondria[24] could account for this rapid loss of coenzyme I, especially since a pronounced requirement for coenzyme I may also be shown by damaged mitochondria from normal tissues[22]. Swelling and consequent damage to isolated respiring liver mitochondria is prevented and even reversed by addition of adenosine triphosphate and coenzyme I [25], and it is likely, therefore, that the addition of coenzyme I prevents similar changes in isolated tumour mitochondria.

The 'coenzyme I-effect' observed by Weinhouse in the respiration of tumour mitochondria, therefore, reflects the low rate of coenzyme I synthesis in the tumour cell. Furthermore, the high fermentative activity of tumour cells[26,27] and of embryonic cells[22] may also be a consequence of the low rate of coenzyme I synthesis causing a kinetic imbalance of cytoplasmic enzyme systems and thus structural abnormalities in the cytoplasm.

Modification of the Rate of Synthesis of CoenzymeI as a Basis for Chemotherapy of Cancer

The findings already discussed show that in rapidly growing cells synthesis of new cell material occurs against a limiting rate of supply of coenzyme I from the nucleus. Continued cell growth immediately after cell division will cause the concentration of cytoplasmic coenzyme I to fall. It is assumed that when this declines to some critically low level, consequent interaction between the nucleus and cytoplasm causes the cells to divide again, thus providing more nuclear enzyme in relation to the amount of cytoplasm. The interaction which induces division probably involves a 'feed-back'[28] mechanism, since the synthesis of adenosine triphosphate in the cytoplasm is dependent on the supply of coenzyme I from the nucleus (for oxidative reactions), and synthesis of coenzyme I in the nucleus on supply of adenosine triphosphate from the cytoplasm. If each cell division leads to a net increase of coenzyme I–pyrophosphorylase in the nucleus, the concentration of coenzyme I will increase and thus permit of greater production of cytoplasm before another cell division is induced. In normal embryonic tissues which have no permanent lesion of coenzyme I synthesis, this will lead to a continual decline with time in the rate of cell division and so permit of normal differentiation and stabilization of the adult tissue. This interpretation is consistent with observations on fœtal, young, and adult mouse liver[8] and on regenerating mouse liver[21].

However, if there is a genetic lesion which prevents an increase in the activity of the coenzyme I-synthesizing enzyme, then cell division will not correct the limitation in the supply of coenzyme I, and synthesis of new cell material will rapidly lead to the interaction between the nucleus and cytoplasm which induces renewed cell division. The cells so formed would have the relatively high ratio of nuclear volume to cytoplasmic volume characteristic of many tumours, and cell division would remain uncontrolled. It is therefore considered that tumour cells differ from normal embryonic cells in lacking the inherited potential for increasing the amount of coenzyme I–pyrophosphorylase in response to the stimulus of cell division. Tumour cells may arise from normal adult cells by depletion of the enzyme system associated with synthesis of coenzyme I–pyrophosphorylase. Other factors which follow this primary defect may account for the invasiveness and other distinguishing features of malignant tissues.

Since the activity of the coenzyme I–pyrophosphorylase is very low in the tumour as compared with the normal adult cell[5,8], and is probably close to the critical level for cell survival, inhibition of this enzymic activity would probably be lethal to the tumour cell. However, the much greater activity (about five-fold) in the comparable normal cell ensures that a similar percentage inhibition would probably have little serious effect on the metabolism of the normal tissue, especially if the inhibition is relieved soon after death of the malignant cells. For chemotherapy, the characteristics required of the compound are as follows. (1) It should specifically inhibit the coenzyme I–pyrophosphorylase. (2) Desirably, it should be taken up preferentially by the tumour cells, which may have surface properties differing from those of normal adult cells[29]. Moreover, it should not be excluded by nuclear or cellular membranes. (3) It should not react with other enzyme systems which may modify or destroy it.

No organic inhibitors of the coenzyme I–pyrophosphorylase have yet been described. The anti-tumour agent, acetyl podophyllotoxin ω-pyridinium chloride, apparently causes a marked fall in this activity of tumour tissue in treated animals, but has no effect on the tissue *in vitro*[30]. In this Department, therefore, inhibitors are being sought which will interfere with the area of attachment of nicotinamine mononucleotide to the enzyme (see equation 2), since compounds which would react with other sites would probably inhibit also other essential pyrophosphorylases. Pyridinium compounds are being studied initially with purified enzyme from pig liver[31]. It is hoped to be able to reduce the number of compounds to be synthesized and evaluated by prediction of the relative effectiveness of substituents on the pyridine ring[32].

The powerful growth inhibitor and anti-leukæmic agent 2 : 4 : 6-triethyleneimino-1 : 3 : 5-triazine causes a marked decrease of coenzyme I in tumour cells, apparently by accelerating degradation rather than by inhibiting synthesis[33]. This and similar compounds may therefore be valuable for potentiating the action of an inhibitor of coenzyme I–pyrophosphorylase. As a long-range approach, investigation of the synthesis of the nuclear coenzyme I–pyrophosphorylase may also be of value in that activation of this system could possibly lead to production of sufficient coenzyme I to prevent division of tumour cells.

This new approach involving specific inhibitors and activators of coenzyme I synthesis would appear to deserve consideration alongside other biochemical approaches to cancer chemotherapy which were recently discussed in *Nature*[34]. The malignant cell has been cited here as a special example of uncontrolled growth. However, it is believed that active compounds of the type envisaged here may have wide application for control of growth and differentiation of normal cells, especially of plants. The problem of chemical control of coenzyme I synthesis is therefore being actively investigated in this Department.

Most of the ideas expressed here were formulated while I was on the staff of the Department of Biochemistry of the University of Melbourne, where in 1953 I initiated a programme of investigation of the biochemistry of tumours. I wish to thank Prof. V. M. Trikojus, professor of biochemistry, and Prof. S. Sunderland, dean of the faculty of medicine, University of Melbourne, for their encouragement. I am grateful to the Anti-Cancer Council of Victoria for financial assistance for the work carried out with the collaboration of Miss M. Branster.

A REMARKABLE SOLAR RADIO EVENT

By STAFF OF THE IONOSPHERE AND RADIO ASTRONOMY SECTION OF THE NETHERLANDS TELECOMMUNICATIONS SERVICES, THE HAGUE

On November 4, 1957, a large increase in solar radio noise was observed on a frequency of 200 Mc./s. at the receiving station 'Nera' of the Netherlands Telecommunications Services. The increase started rather abruptly at 0848 U.T. and lasted for more than 5 hr., the greatest intensity being reached at about 0930 U.T., when it amounted to approximately 900 times the noise level of the quiet Sun. The smoothed intensity level showed considerable fluctuations with periods of the order of a few minutes. No solar flare has been reported as occurring near the onset of the radio event, nor was a sudden ionospheric disturbance observed. The phenomenon manifested itself over a considerable frequency-range in the metre wave-length band. It was also observed at 169 Mc./s. by the observatories at Humain (Belgium) and Nançay (France), but it was altogether absent on the decimetre–centimetre wave-length range and on a wave-length near 6 metres. The radiation was 100 per cent left-handed circularly polarized. The position of its source, as determined at 1125 U.T. with a two-element interferometer operating on a frequency of 250 Mc./s., was about 0·1 solar radius east of the centre of the solar disk. During a period of 2 hr., centred around local noon, no systematic displacement of the source of enhanced radiation was observed.

The lack of correlation with a solar flare or associated effects, and the absence of disturbances on the decimetre–centimetre wave-lengths, must be considered as rather exceptional for so large a 200-Mc./s. event. However, the extraordinary character of this great radio phenomenon was particularly apparent from records obtained with a negligible time-constant. Some were recorded with a high-speed recording paper (5 mm./sec.). These records revealed short-period fluctuations of intensity, with a period of some 0·2–0·3 sec., of a type not observed before at the Nera Observatory, altogether different from the kind ordinarily occurring during a noise storm. Part of this variability, strongly reminiscent of the ionospheric scintillations of radio sources (Fig. 1, 1), showed an oscillatory type of intensity fluctuation (Fig. 1, 2). In other parts of the record there was a preponderance of decreases in intensity, short dips of a fading character, which were also present on records obtained by the Nançay Observatory on 169 Mc./s. (for copies of which we are indebted to M. A. Boischot). During the later stages of the radio event dips and oscillations of a longer duration, of the order of 0·1 min., occurred. These could also be identified on slow-speed records obtained at 200 Mc./s. simultaneously at Nera and at Paramaribo (Surinam) with time-constants of, respectively, 1 sec. and 0·3 sec. This proves that the latter variability (which was also of a very uncommon type) certainly cannot be ascribed to ionospheric effects. No ionospheric scintillation of radio sources of any importance was observed at the Jodrell Bank Experimental Station or at the Mullard Radio Astronomy Observatory on November 4. Ionospheric scintillations of so short a period have never, in fact, been observed in Cambridge (Dr. A. Hewish, private communication). The very short-period fluctuations of intensity must also, therefore, be ascribed to solar conditions.

All these facts together justify the conclusion that the radio phenomenon which occurred on November 4 is of a new, so far unknown type of great rarity. It should be noted that this peculiar type of variability is revealed only by a recording instrument

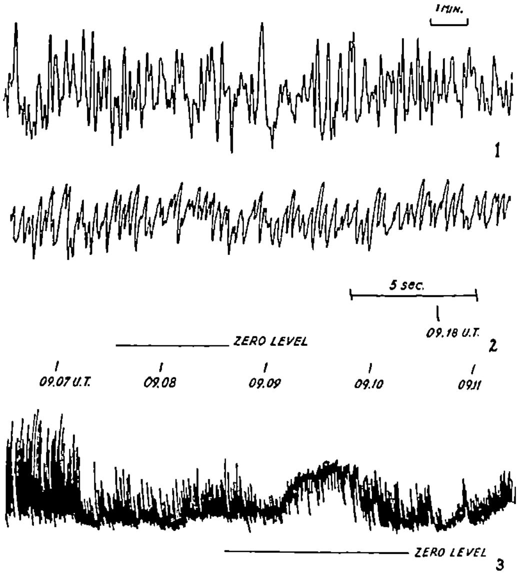

Fig. 1. 1. Scintillations of the radio source Cas *A* on 200 Mc./s.
2. High-speed record of solar radio emission on 200 Mc./s.
3. Slow-speed record of solar radio emission on 200 Mc./s.

with a time-constant no greater than a very small fraction of a second. With slow-speed recording paper one then simply obtains a very blurred record (see Fig. 1, 3), which might suggest some kind of interference. In the present case, however, the possibility of interference is ruled out, both by the confirmation from the other observatories, and by the regular pattern of the interferometer curve. The true nature of the intensity fluctuations can only be ascertained by high-speed recording. This is perhaps the reason, together with its extreme rarity, why this type of radio event has not been reported before. It differs from the so-called 'non-selective fading', observed by Payne-Scott and Little[1] on 62 and 98 Mc./s., in that the intensity fluctuations have a much shorter period.

The occurrence of fluctuations in intensity of the type shown in Fig. 1, 1, suggests that, in special circumstances, solar coronal gas may give rise to scintillation effects, possibly analogous in mechanism to ionospheric scintillations, but more varied in character. Irregularities in the solar corona may be responsible for focusing and defocusing effects and perhaps to absorption effects. It is of interest to consider the possibility that the occurrence of storm-bursts during an ordinary noise storm may be due to a focusing mechanism.

The radio event of November 4 occurred quite unexpectedly. The importance of observing such rare phenomena as completely as possible makes it very desirable that solar radio instruments should be operated on a routine basis, however specialized in type.

We are indebted to Dr. R. Coutrez of the Humain Observatory and to Dr. Boischot of the Nançay Observatory for providing us with copies of their records; and to the Jodrell Bank and Mullard Radio Observatories for information on the scintillation of radio sources on November 4.

SOLAR ACTIVITY AND THE IONOSPHERE

By C. M. MINNIS

Department of Scientific and Industrial Research, Radio Research Station, Slough

THE recent unprecedented high levels of solar activity, as indicated by sunspot numbers and described by Dr. M. A. Ellison[1], have been accompanied by equally exceptional conditions in the ionosphere. During the sunspot cycle there is no appreciable change in the amount of visible light or heat radiation emitted by the Sun, but in other parts of the spectrum this is no longer true. As compared with June 1954, when solar activity was at a very low level, the intensity of the ultra-violet and X-radiation which is responsible for the existence of the *E*-layer of the ionosphere had increased by a factor of 3·2 in September 1957, 3·6 in October and 3·1 in November. These values all exceed the previous maximum of 3·0 in May 1948 and are the highest recorded values since ionospheric measurements were begun at Slough in 1931.

The figures quoted above are based on the critical frequency of the *E*-layer. Unfortunately there is, as yet, no adequate theory on which similar estimates of the intensity of the *F*2-layer ionizing radiation could be based. However, in November 1957 at Slough, the mean value of the electron density at the peak of the *F*2-layer rose to $2 \cdot 6 \times 10^6$ cm.$^{-3}$, a value which exceeds the previous highest value, for November 1947, by 9 per cent. In October 1957 the density was much lower than in November but, after making an appropriate allowance for the normal seasonal changes in the *F*2-layer, it may be concluded that the mean intensity of the ionizing radiation in October exceeded that in November, thus confirming the conclusion reached using the *E*-layer results.

The large changes in the intensity of the ionizing radiation which are associated with the sunspot cycle lead to corresponding variations in the structure and the electron density of the layers of the ionosphere. The complicated ways in which these layers change are of great importance during investigations into the chemical constituents and the atomic processes which determine the electrical properties of the upper atmosphere. These changes are not, however, solely of academic interest, because the electron density controls the critical frequencies of the layers which are responsible for the reflexion of radio waves; a wave which is normally incident on an ionospheric layer will not be reflected for frequencies greater than the critical frequency. At very oblique angles of incidence, the greatest frequency at which a wave will be reflected will be 3–3·5 times the critical frequency for reflexion at the *F*2-layer and 5 times for the *E*-layer.

Reports from the B.B.C. receiving station at Tatsfield show that during October 1957 radio stations in the United States could, on the average, be received at frequencies of 37·5 Mc./s. in the early afternoon; in November this figure had risen to 46·9 Mc./s. On individual days even higher frequencies could be received: 50·7 Mc./s. in October and 55·3 Mc./s. in November. These observations are consistent with the reception, when propagation conditions are favourable, of B.B.C. television signals on 45 Mc./s. in the United States and in South Africa. An even more spectacular achievement, which has recently been reported in the Press, was the reception of B.B.C. television pictures in Australia at the end of November.

The mean value of the critical frequency of the $F2$-layer at Slough at noon was 13·4 Mc./s. in October and 14·6 Mc./s. in November; on individual days, values of more than 16 Mc./s. were fairly common. In the light of these figures, it is not difficult to account for reports, such as those mentioned above, of the propagation of radio waves in the very-high-frequency band over distances far in excess of those expected in normal circumstances.

It may be recalled that even near sunspot minimum in 1954 it was not uncommon to find instances where European radio stations operating in the very-high-frequency band interfered with television and other radio services in southern England. The propagation in such circumstances must be attributed, not to reflexions from the $F2$-layer, but from the sporadic E-layer or, alternatively, to effects associated with the refractive properties of the troposphere during certain meteorological conditions. Fortunately, such interference is not sufficiently frequent to cause serious difficulties in planning radio networks in the very-high-frequency band. On the other hand, the occurrence of fairly regular reception of distant very-high-frequency stations as a result of $F2$-layer propagation may prove to be embarrassing to some radio services for most of this winter. Although the seasonal fall in $F2$-layer ionization during the first month or two of 1958 may give some respite from such difficulties, the seasonal rise in February and March 1958 will probably lead to a recurrence of interference problems except in the unlikely event of a very rapid fall in solar activity over the next few months.

An examination of the twenty sunspot cycles which have occurred since 1749 shows that the present one and its predecessor must be regarded as having maxima which are well above the average. Communication engineers would certainly not be justified either in making long-term plans based on experience gained in 1947–48 or 1957–58, or in assuming that the steady rise in the level of the three consecutive maxima beginning with that of 1927 is part of a long-term trend.

Peaks in solar activity which are in any way comparable to the present one seem to occur only about once in a hundred years. Such an event may produce problems for radio engineers, but from the point of view of those engaged in upper atmosphere research, it may be said of the fortunate coincidence of the 1957–58 peak with the I.G.Y.: "never had mortal man such opportunity . . .".

The work described above was carried out as part of the programme of the Radio Research Board, and is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

FOSSIL ALGAE IN INDIA

By Prof. L. RAMA RAO

Bangalore

TWENTY-FIVE years ago, I reported in *Nature* the discovery of abundant fossil algae in the Cretaceous rocks of South India, especially in one of the limestones belonging to the youngest division, the Niniyur group (Danian), of the Trichinopoly area. (The Cretaceous of the Trichinopoly Dt., South India, is divided into four groups. Starting from the oldest, these are: (*a*) the Utatur; (*b*) the Garudamangalam (Trichinopoly); (*c*) the Ariyalur; (*d*) the Niniyur. The entire succession ranges in age from the upper Albian to the Danian of the European stratigraphical scale. A full description of these rocks has been recently given by me elsewhere[1].) Further examination of all the limestones of this group and the associated flints and cherts which are their silicified representatives yielded a rich harvest of fossil algae of various kinds; these were studied and described by me in collaboration with Dr. Julius Pia, of Vienna[2]. Prior to this discovery, our knowledge of fossil algae in India was confined to casual references and brief descriptions of a few stray and solitary occurrences here and there.

The finding for the first time in India of a rich assemblage of fossil algae in the beds of the Niniyur group was therefore an event of considerable interest, and the fact that this collection included several new genera and species of the three main families, Solenoporaceae, Corallinaceae and Dasycladaceae, made it particularly noteworthy. Many of these forms show features of significant phylogenetic and evolutionary importance, the entire collection constituting, according to Pia, "the most interesting algal flora" he had ever studied.

The publication of the memoir in 1936 dealing with the Niniyur algae thus opened out a whole field of research, and it is gratifying to note that many valuable contributions to our knowledge of fossil algae in India, especially from the Cretaceous and Eocene rocks, have since been made by a number of workers. The object of this article is to give a summary of these contributions and indicate their scope; for fuller details and descriptions, the reader may refer to the original papers published from time to time, of which the more important are given at the end of this article.

In the rocks of the Niniyur group itself, more algae have since been noticed, including *Neomeris*, *Acicularia*[8], *Clypeina*[3,7] and *Piania*; along with these there is also the 'unexpected' occurrence of a primitive form like *Holosporella*. The coral-reef limestones (Upper Albian) at the base of the Trichinopoly

Cretaceous succession have also revealed a rich algal flora, indicating that the algae played quite an important part in the building up of these reefs. Of outstanding significance is the occurrence in several rocks of this area, including the Niniyurs, of species of *Solenopora*[3], thus showing that the time-range of this genus extended up into the late Cretaceous, where it existed side by side with *Archaeolithothamnium*. Such an association of these two genera in the Cretaceous also provides valuable material for the study of the mutual chronological and evolutionary inter-relationships of the two important families of fossil algae which they represent. In the year 1937, J. Pia, S. R. N. Rao and K. S. Rao described fossil algae, including *Terquemella*, *Acicularia*, *Acetabularia* (?), and four species of *Neomeris* from the intertrappean beds near Rajahmundry[4]. This assemblage, which shows a distinct Tertiary aspect, is important not only in itself but also in throwing light on the age of the associated traps. A more recent examination of some of these intertrappeans which I have made shows that there are more of these Dasycladaceae here, probably including several other forms in addition to those mentioned above.

From the Lockhart limestone (Palæocene) of the Samana Range (now in Pakistan) S. R. N. Rao described in 1941 a rich algal flora belonging to the Melobesieae[5]. This includes several new species belonging to the genera *Archaeolithothamnium*, *Lithophyllum*, *Mesophyllum* and *Melobesia*. It may be noted that one of these species of *Archaeolithothamnium* (*A. samanensis*) found here shows "a concentric arrangement of the hypothallial rows"—a character which is considered as a distinctive feature of the genus *Lithophyllum*. Associated with these algae here, the solitary occurrence of a *Neomeris* (*Larvaria* ?) has also been noticed. From a limestone in Sind (Pakistan) probably also of Palæocene age, S. R. N. Rao and K. P. Vimal have quite recently (1955) described certain species of *Acicularia* and *Indopolia* representing the Dasycladaceae, together with the form *Boueina* belonging to the Codiaceae.

The occurrence of an abundant algal flora including both the Corallinaceae and Dasycladaceae in some of the limestones of doubtful Cretaceous or Eocene age of Assam was noticed in the year 1940; the Corallinaceae in this material have been studied in detail by K. S. Rao and the results embodied in a paper which he published in 1943[6]. Both the sub-families Melobesieae and Corallinae are represented here; of the former, which are by far the more abundant, he has described five species of *Archaeolithothamnium*, five of *Lithothamnium*, and one each of *Mesophyllum*, *Melobesia* and *Distichoplax*; and of the latter there is a new species of *Corallina*. The entire assemblage clearly indicates that the containing rocks are of early Tertiary age—a conclusion also supported by recent stratigraphical studies. The Dasycladaceae found in this material are yet to be described. These Assam limestones evidently constitute a rich storehouse of a varied and well-preserved algal flora, worthy of further attention.

Another important area where numerous fossil algae have been recently noticed is the Salt Range. The first report of this occurrence in the Eocene beds of this area (now in Pakistan) was made by me and K. S. Rao in 1939, recording the presence of *Dissocladella*, *Acicularia* and *Neomeris*, together with some surviving primitive forms like *Oligoporella* and *Diplopora*. More recently (1953) a rich algal flora from the lower Eocene limestones (of the Nammal gorge) of this region has been described by C. P. Varma[8]. He has recognized here some new species—three of *Archaeolithothamnium*, two of *Mesophyllum* and one of *Lithophyllum*; in this connexion he has also contributed a valuable discussion on the affinities of these and allied genera, especially in regard to *Mesophyllum*, where we can observe "a complete gradation from the *Lithothamnium* type to the *Lithophyllum* type of tissue among the various species of *Mesophyllum*". The same material also contains the remains of an alga very similar to the interesting form *Solenomeris*. Attention may also be directed to the three species of *Gymnocodium* recently described (1953) from the Permian beds of the same area.

The following classified list gives an idea of the variety and abundance of fossil algae described so far from the above areas: Dasycladaceae: *Holosporella* (2), *Triploporella* (1), *Oligoporella*, *Diplopora*, *Dissocladella* (1), *Indopolia* (2), *Acicularia* (4), *Orioporella* (1), *Neomeris* (9), *Clypeina* (3), *Terquemella* (1), *Acetabularia* (?) and *Piania* (1); Corallinaceae: (Melobesieae) *Archaeolithothamnium* (14), *Mesophyllum* (5), *Lithophyllum* (2), *Lithothamnium* (6), *Melobesia* (2), *Solenomeris* (1) and *Distichoplax*; (Corallinae) *Corallina* (1); Solenoporaceae: *Parachaetetes* (1) and *Solenopora* (3); Chaetophoraceae: *Palaeachlya*; Codiaceae: *Gymnocodium* (1) and *Boueina*. (The figures within brackets indicate the number of new species recognized.)

From the above brief review of the results of work done in India since the occurrence of abundant algae was first reported in 1931, it becomes clear that these algal remains "offer a vast field of research of which only the fringe has yet been touched". Apart from the Cretaceous and Eocene rocks which have yielded most of the forms mentioned above and will no doubt reveal many more on further examination in due course, we have a whole series of marine sedimentary rocks in India of earlier ages which are still 'untouched' from the point of view of their fossil algae. The farther back we go in time in this sedimentary succession, the more interesting will be their algal contents; and when we go down to the Precambrian rocks, of which we have such a good development in India, the search for fossil algae becomes positively exciting. A beginning in the study of the Precambrian algae in India has just been made by the record of a few remains by R. C. Misra in the rocks of the Vindhyan system, and of some algal (?) structures in the even older Cuddapah formations by M. R. S. Rao. The scope and opportunities for further explorations in India in the study of Precambrian algae are practically unlimited.

It is thus evident that a most promising field dealing with the study of fossil algae from rocks of various ages in India is still awaiting attention. It is earnestly hoped that this fruitful and fascinating line of research will be taken up and pursued in earnest before long; the results of these studies will undoubtedly be of the greatest value alike to the stratigraphical geologist and to the palæobotanist.

Presence of Triiodothyronine in Fowl

THE observation of an unknown iodinated compound as a regular constituent of plasma and thyroid tissue of mice and rats[1-3] led to the discovery of 3-5 : 3′-triiodo-L-thyronine[4-7]. It has been established that triiodothyronine possesses all the thyroid hormone qualities of thyroxine when tested in a large number of species[8] and is more potent than thyroxine when tested by a variety of methods *in vivo* in mammals and amphibians[9]. Thus triiodothyronine has come to be recognized as being of physiological importance in laboratory mammals and man. However, little is known of the distribution of triiodothyronine in other classes of vertebrates, beyond the fact that it has been found in reptiles[10]. It seemed of interest to ascertain whether birds have the capacity to synthesize this compound.

Light Sussex cockerels, 100 days old, were given 250 μc. of iodine-131 by the subcutaneous route. 24 hr. later they were killed while under light ether anæsthesia, and the thyroid glands removed, minced and placed in ammonium-chloride ammonia : urea buffer (*p*H 8·6). Trypsin (1 mgm.) was added, and the glands were allowed to incubate for 24 hr. at 35° C. with a further addition of trypsin after 12 hr. After acidification with hydrochloric acid, the hydrolysate (*p*H 2·6) was extracted three times with butanol and the combined butanol extracts reduced to dryness under diminished pressure. The residue was taken up in methanol : ammonia (3 : 1) and applied to Whatman No. 1 filter paper for ascending chromatography in *n*-butanol–acetic acid–water (78 : 10 : 12 v/v) or *n*-butanol–dioxane (80 : 20 v/v) saturated with 2 *N* ammonium hydroxide systems. Thyroxine, triiodothyronine, diiodotyrosine, monoiodotyrosine and iodide were added as carriers. The positions of the carriers were visualized in ultra-violet light, and the triiodothyronine and/or thyroxine areas of the paper cut out, eluted with methanol–ammonia and re-chromatographed in a single dimension in *n*-butanol–dioxane–ammonia or in two dimensions in both solvent systems together with the appropriate carriers. The radioactivity of the paper was localized by radioautography and/or scanning with an automatic recording β-counter. The carriers were localized with diazotized sulphanilic acid and palladium chloride.

The results of two such experiments are shown in Fig. 1, and in both cases radioactivity was noted in the area of triiodothyronine. Other experiments, carried out on both males and females, from a cross between Light Sussex and Rhode Island Reds, in some cases following stimulation of the thyroid gland with thyroid-stimulating hormone, have confirmed these observations, but in no case was the percentage of radioactivity ascribed to triiodothyronine higher than 1 per cent of the total radioactivity extractable with butanol from the gland, or more than 5 per cent of the thyroxine radioactivity.

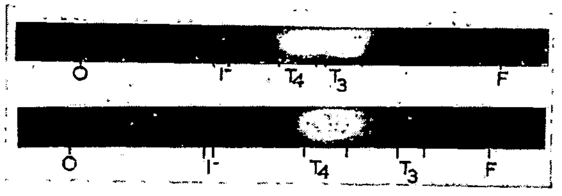

Fig. 1. Autoradio chromatograms of hydrolysed, butanol-extracted bird thyroid glands rechromatographed in butanol–dioxane–ammonia system. Bottom: elution of T_4–T_3 spot from a butanol–acetic acid–water chromatogram. Top: elution of T_3 spot from a butanol–dioxane–ammonia chromatogram. O, origin; I^- iodide; T_4 thyroxine; T_3, 3 : 5 : 3′-triiodothyronine

It may be concluded from the present experiments that the thyroid gland of the bird possesses the capacity to synthesize triiodothyronine, and that triiodothyronine presumably has a role in thyroid physiology in this class of vertebrates. This finding may take on added interest in the light of two curious findings, that birds have a low plasma protein-bound iodine value[11] and that triiodothyronine is no more potent than thyroxine in various biological tests done in birds[12,13].

Enzymes of the Tricarboxylic Acid Cycle and Cytochrome Oxidase in the Fat Body of the Desert Locust

VARIOUS workers have shown the presence of some or all of the enzymes of the tricarboxylic acid cycle in insect muscle sarcosomes (for example, in *Musca domestica*[1], *Phormia regina*[2], *Apis mellifera*[3]) or in particulate fractions prepared from whole insects (for example, from *Aedes aegypti*[4]); but other specific insect tissues have received little attention. The insect fat body is often one of the most conspicuous organs and is known to carry out many reactions involving nitrogen metabolism[5]; but almost nothing has been recorded of other oxidative capabilities. As the biochemical function of the fat body is probably not primarily concerned with energy production (unlike muscle sarcosomes), it appeared of interest to examine this tissue.

The desert locust, *Schistocerca gregaria* Forsk., was used as a source of the fat body tissue which was carefully dissected out and gently homogenized in a Potter–Elvehjem blender. Fifth instar nymphs were used for most of the work. The presence of a number of enzymes associated with the tricarboxylic acid cycle was demonstrated in this tissue for the first

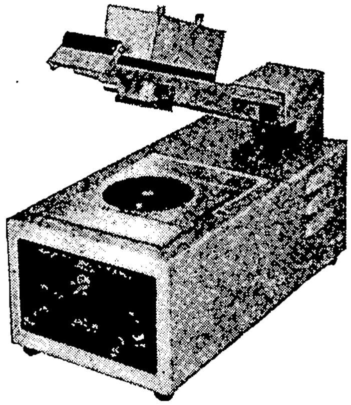
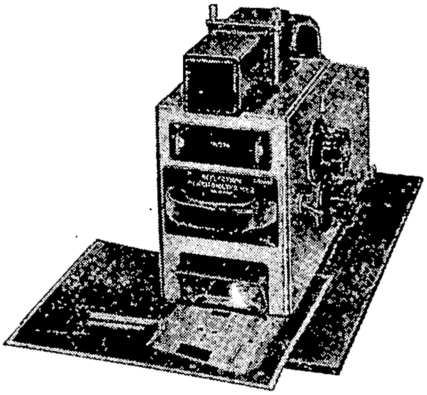
ACCURATE MEASUREMENT OF LIGHT & COLOUR





Based on the accurate, sensitive Baldwin Photometer, there is a wide range of densitometers available for the measurement of density and colour in all forms.

For film negatives and transparencies the Baldwin Transmission Densitometer will measure high densities on very small areas. Photo prints, paper, plastic sheet and similar substances can be tested for colour and density with the Baldwin Reflection Densitometer. A further attachment is available for measuring turbidity and colour of liquids.

★ All of these instruments are fully detailed in leaflet F-117, sent gladly on request.

BALDWIN scientific instruments

BALDWIN INSTRUMENT COMPANY LIMITED · DARTFORD · KENT · Telephone: 2948

Only very occasionally does a new material appear that has a widespread potential throughout industry.

Here, though, is just such a product — a unique material that deserves your fullest understanding.

Refrasil

is the name given to a lightweight fibrous silica material, of very fine diameter, which is capable of withstanding continuously temperatures in the order of 1,000°C, or for short periods, even above. It has outstanding thermal insulating characteristics at elevated temperatures, as well as being an excellent high temperature electrical insulator. Like fused silica it has a high resistance to thermal shock and to chemical attack from acids.

It is available as batt, felted wool, cloth, tape, sleeving, bulk fibre, cord, and yarn.

There are many other things well worth your knowing about Refrasil; we have incorporated them all in a brochure which we would like to send you.

time. Using spectrophotometric assay methods, the presence was shown of a specific triphosphopyridine nucleotide-linked *iso*citric dehydrogenase, aconitase and fumarase. A diphosphopyridine nucleotide-linked malic dehydrogenase was demonstrated both by optical observation of the reduction of oxidized cytochrome *c* in the presence of cyanide, and manometrically by measurement of oxygen uptake in a Warburg apparatus. Cytochrome oxidase was present in the fat body, and was completely inhibited by $7\cdot5 \times 10^{-5}$ *M* cyanide and 94 per cent inhibited by 1×10^{-3} *M* azide. The cytochrome oxidase activity of the fat body showed a striking variation with age in the fifth stadium. It fell from a relatively high value at the beginning to about one-thirtieth towards the end of the stadium (that is, about 160 hr. after the fourth moult), and then rose sharply at the time of the fifth and final moult, and was at a high level in the young adult.

All efforts to demonstrate the presence of the condensing enzyme, succinic dehydrogenase and α-ketoglutarate oxidase were unsuccessful, both by optical and manometric methods. The apparent absence (or presence at a very low level below the sensitivity of the assay methods) of these key enzymes of the tricarboxylic acid cycle (although other enzymes which can take part in the operation of the cycle could readily be assayed), suggests that the cycle may not play an important part in the intermediary metabolism of the fat body of the locust.

We are indebted to the Anti-Locust Research Centre for financial support and encouragement in this work.

Phosphorylase Activity of Primary Rat Liver Cancer

THE level of glycogen in the majority of tumours is considerably lower than in the normal homologous tissues[1]. According to Dickens and Weil-Malherbe[2] the glycogen content of primary rat hepatoma is lower than that of normal rat liver. As found recently by Goranson *et al.*[3], the phosphorylase activity of a transplantable rat hepatoma is very low. According to these authors, the addition of adenosine 5-phosphate greatly increases the phosphorylase activity of hepatoma tissue, up to the values found with normal rat liver. Hence the low content of glycogen in hepatoma might be due to a lack of adenosine 5-phosphate, rather than a deficiency in the amount of the phosphorylase itself. On the other hand, Le Page[5] found that rat hepatoma contains approximately twice as much adenosine 5-phosphate as normal rat liver. We have therefore studied the phosphorylase activity of primary rat liver carcinoma and the activating effect of adenosine 5-phosphate on it.

Discrete rat liver tumour nodes were selected for our experiments. The tumours were induced by feeding rats for 5 months with a semi-synthetic diet containing 0·6 per cent 4-dimethylaminoazobenzene[4]. Experimental and control animals were fasted for 24 hr. before killing; the tumour nodes were separated from the adjacent parenchyma, necrotic areas being carefully removed, and were homogenized at 0° with isotonic potassium chloride in a Potter–Elvehjem glass homogenizer. As it was found that the degree of homogenization is of importance for the phosphorylase activity, all experiments were made with homogenizers having an optimal clearance according to Potter[6].

Phosphorylase activity was determined by Sutherland's method[7], slightly modified according to the conditions of our experiments: the reaction was started by the addition of 0·5 ml. enzyme mixture to 1·0 ml. substrate solution (*p*H 6·1, glass electrode) containing glucose-1-phosphate (0·05 *M*), glycogen (5·7 mgm./ml.) and sodium fluoride (0·05 *M*). The enzyme mixture had the following composition: 0·5 ml. 2 per cent homogenate, 0·3 ml. *M* sodium fluoride, 0·2 ml. distilled water. When the activating effect of adenosine 5-phosphate was to be studied, 0·2 ml. of a solution of adenosine 5-phosphate (Pabst) was added, instead of water (final, 0·04 *M*). Test-tubes were incubated at 30°. At 0, 10 and 20 min., samples were taken, deproteinized with an aliquot of 5 per cent trichloracetic acid, and centrifuged. Inorganic phosphorus was determined in the supernatant by the method of Fiske–SubbaRow as adapted to a photoelectric colorimeter.

The phosphorylase activity of homogenates from normal rat liver (5 animals) and from primary rat liver cancer (7 animals) was studied. The effect of adenosine 5-phosphate (0·04 *M*), adenosine (0·04 *M*) and guanosine (0·02 *M*) was also investigated. In all experiments only fresh homogenates were used. The results of our experiments (Fig. 1) show that the phosphorylase activity of primary rat liver cancer is considerably lower (about one-third) than that of normal rat liver. The inorganic phosphorus released has the following average values: for tumour tissue,

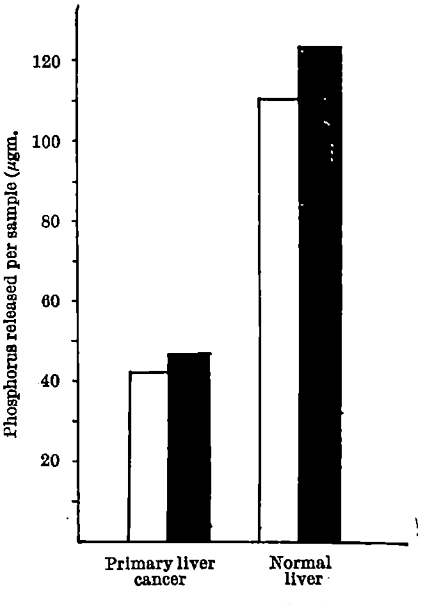

Fig. 1. Phosphorylase activity of normal rat liver and primary rat liver cancer. White, without adenosine 5-phosphate; black, with adenosine 5-phosphate

42·0 μgm. phosphorus, and for normal liver tissue, 109·8 μgm. phosphorus per sample in the conditions of our experiment. The adding of adenosine 5-phosphate in the above-mentioned concentrations increased the phosphorylase activity by 11 per cent for the primary rat liver carcinoma and by 11·2 per cent for normal rat liver. Adenosine and guanosine have no marked effect on phosphorylase activity.

The results of our experiments suggest that the low glycogen content in hepatic tumours could well be explained by the low phosphorylase activity of these tumours. Contrary to the data of Goranson *et al.*[3], our experiments indicate that rat liver tumours are characterized by a real decrease in the enzyme protein and not by a lack of adenosine 5-phosphate, the phosphorylase in tumour and normal liver homogenates being activated to the same degree by adenosine 5-phosphate.

Occurrence of Independent Systems for the Cleavage of Folic Acid and Citrovorum Factor in Rat Liver

RECENT work has demonstrated that extracts from animal tissues can actively degrade folic acid[1,2] and citrovorum factor[3] at the C_9—N_{10} linkage with the liberation of a diazotizable amine. Whether the same enzyme systems are involved in the cleavage of the two substrates is, however, not established. The horse-liver fraction which has been shown to degrade citrovorum factor was inactive towards folic acid[3]. In a recent paper, Dinning *et al.*[4] have suggested that the transformation of folic acid into a diazotizable amine by slices and homogenates of rat livers takes place with the intermediate formation of citrovorum factor. In the course of studies on folic acid degradation by purified fractions from rat liver, we prepared extracts which degrade folic acid but not citrovorum factor. Furthermore, *A*-methopterin has been found to inhibit selectively the cleavage of folid acid in acetone-dried powder extracts, but the citrovorum factor remains unaffected.

Three kinds of rat liver extracts were used. Fresh liver extracts were prepared by extraction of the liver in 0·15 *M* phosphate buffer, *p*H 5·5 and dialysis in water (0–4° C.) for 20 hr.; acetone–powder extracts were made in the usual way and phosphate buffer *p*H 5·5 added to give 10 per cent extracts.

Extracts of acetone–powders of liver prepared as above were treated with solid ammonium sulphate (30–70 per cent) in the cold, and the precipitate suspended in water and dialysed for 20 hr. in distilled water (0–4° C.).

Enzyme activity was determined by following the liberation of the aromatic amine, according to Bratton and Marshall[5]. Non-substrate blanks were determined by incubating tubes with all constituents of the reaction mixture except folic acid. The latter was added at the end of the incubation period.

Table 1. CO-FACTOR REQUIREMENTS

The complete system consisted of 150 μgm. of folic acid or citrovorum factor, 0·06 *M* phosphate buffer, $1·5 \times 10^{-3}$ *M* adenosine triphosphate, $1·0 \times 10^{-3}$ *M* manganese chloride, $1·0 \times 10^{-3}$ *M* sodium citrate. $1·0 \times 10^{-4}$ *M* coenzyme I, 1 ml. acetone powder extract. Total volume = 2 ml.; time of incubation, 3 hr.; temperature of incubation, 37° C. (The values given have been corrected for the non-substrate blank)

Sample No.	System	Folic acid degraded at *p*H 5·5 (μgm.)	Citrovorum factor degraded at *p*H 6 (μgm.)
1	Complete system	110·70	36·50
2	Adenosine triphosphate omitted	73·30	8·85
3	Manganese chloride omitted	75·30	17·30
4	Sodium citrate omitted	12·70	12·90
5	Coenzyme I omitted	8·50	9·90
6	All the above omitted	nil	5·5

Table 2. EFFECT OF SOME SUBSTANCES ON ENZYMES DEGRADING FOLIC ACID AND CITROVORUM FACTOR

Complete system as in Table 1. Total volume = 2 ml.; time of incubation, 3 hr.; temperature of incubation, 37° C. (The values given have been corrected for the non-substrate blank.)

Sample No.	Supplements added to the complete system	Folic acid degraded at *p*H 5·5 (μgm.)	Citrovorum factor degraded at *p*H 6 (μgm.)
1	Nil	92·7	35·7
2	*A*-methopterin (10 μgm.)	2·0	35·0
3	L-Glutamic acid (10^{-2} mole)	96·3	35·0
4	N-Formylglutamic acid* (10^{-3} mole)	80·3	31·2

* N-Formylglutamic acid was a gift from Dr. H. R. V. Arnstein.

Table 3. COMPARATIVE DEGRADATION OF FOLIC ACID AND CITROVORUM FACTOR BY DIFFERENT RAT LIVER PREPARATIONS

The incubation mixture consisted of 150 μgm. folic acid or citrovorum factor, same co-factors as in Table 1, and enzyme extract as specified. Buffer, 0·06 *M* phosphate, *p*H 6; time of incubation, 3 hr.; temperature of incubation, 37° C. (The results have been corrected for the non-substrate blank)

Source of enzyme	Folic acid degraded (μgm.)	Citrovorum factor degraded (μgm.)	Ratio of citrovorum factor degraded to folic acid
Dialysed fresh liver extract (1 ml.)	54·3	12·7	0·233
Acetone-powder extract (1 ml.)	79·3	35·4	0·446
30–70 per cent ammonium sulphate fraction from acetone powder extract (0·5 ml.)	87·7	8·5	0·097

Dialysed extracts of acetone-dried powders from rat livers catalyse the liberation of a diazotizable amine from folic acid and citrovorum factor. The activity in presence of either substrate is dependent on coenzyme I, adenosine triphosphate, manganese ions, and citrate. These co-factors have also been found to be necessary for the cleavage of folic acid by chicken liver extracts[2]. Results of experiments given in Table 1 show that omission of any one of the supplements causes a considerable reduction in activity in presence of either substrate. In a publication, which has reached us while this communication was in preparation, Silverman *et al.*[6] report the purification of an enzyme system from hog liver which cleaves citrovorum factor. The latter enzyme differs in some of its properties from the rat liver preparations described here. It is activated by

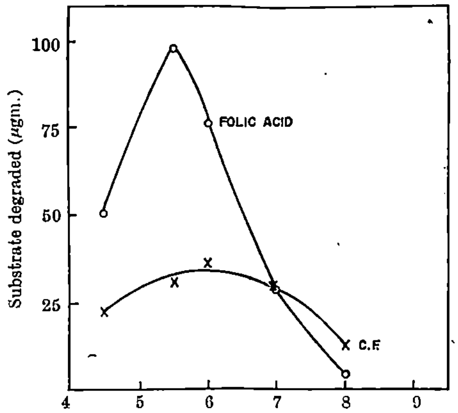

Fig. 1

L-glutamic acid, inhibited by N-formylglutamic acid and apparently does not need any of the above co-factors required by the rat liver system. Results in Table 2 show that L-glutamic acid and N-formylglutamic acid produce negligible effects on the system cleaving folic acid or citrovorum factor in rat liver. *A*-methopterin selectively inhibits the folic acid degradation but citrovorum factor is still unaffected. Furthermore, the folic acid degrading system can be largely separated from the activity towards citrovorum factor by ammonium sulphate fractionation of extracts made from acetone-dried powder (Table 3). The relation of *p*H to activity in presence of the two substrates is illustrated in Fig. 1. The two curves show marked differences. The *p*H optimum for folic acid is at *p*H 5·5 and for citrovorum factor at *p*H 6. Above *p*H 6 the activity in presence of folic acid falls rapidly. This may be a possible explanation for the higher rate of degradation of citrovorum factor obtained by Dinning *et al.*[4] in rat liver homogenates, for their experiments were carried out at *p*H 7·4.

The findings reported here indicate that, in rat liver, separate enzyme systems catalyse the conversion of folic acid and citrovorum factor into a diazotizable amine. The present results do not show whether these conversions proceed through the formation of tetrahydrofolic acid, as has been demonstrated for the system reacting with citrovorum factor in hog liver[6]. Differences between the co-factor requirements and the lack of effect produced by L-glutamic acid indicate, however, that the enzymes catalysing the cleavage of citrovorum factor in the two animal species may not be identical.

We thank Dr. V. R. Khanolkar, director of this Centre, for the facilities made available to us during the course of this work, and the authorities of the Lady Tata Memorial Trust for a scholarship awarded to one of us (U. W. K.).

A Possible Intermediate in the Biosynthesis of Tryptophan : 1-Deoxy-1-N-o-Carboxyphenyl-Ribulose

DURING an investigation of compounds formed by washed cell suspensions of mutant strains of *Aerobacter aerogenes* blocked at various stages in tryptophan synthesis, two strains (*N*3–33 and *N*2–18) were found to form a compound which showed an intense blue-violet fluorescence under ultra-violet light, but the absorption spectrum of which did not correspond to any known compound. Neither strain of *A. aerogenes* would grow in the minimal medium described by Davis and Mingioli[1] unless either tryptophan or indole was added and they were therefore presumably unable to convert anthranilic acid to indole.

Cell suspensions were incubated with a mixture of glucose (0·1 *M*), ammonium chloride (0·005 *M*), magnesium sulphate (10^{-4} *M*) and phosphate buffer (0·1 *M*, *p*H 7·7) as described by Gibson, Jones and Teltscher[2]. After removal of the cells, spectrophotometric examination of the supernatant fluid showed the presence of a compound with a spectrum similar in some respects to that of anthranilic acid (Fig. 1). The compound was readily extracted by ethyl acetate after the supernatants had been acidified, but concentration of these extracts to dryness resulted

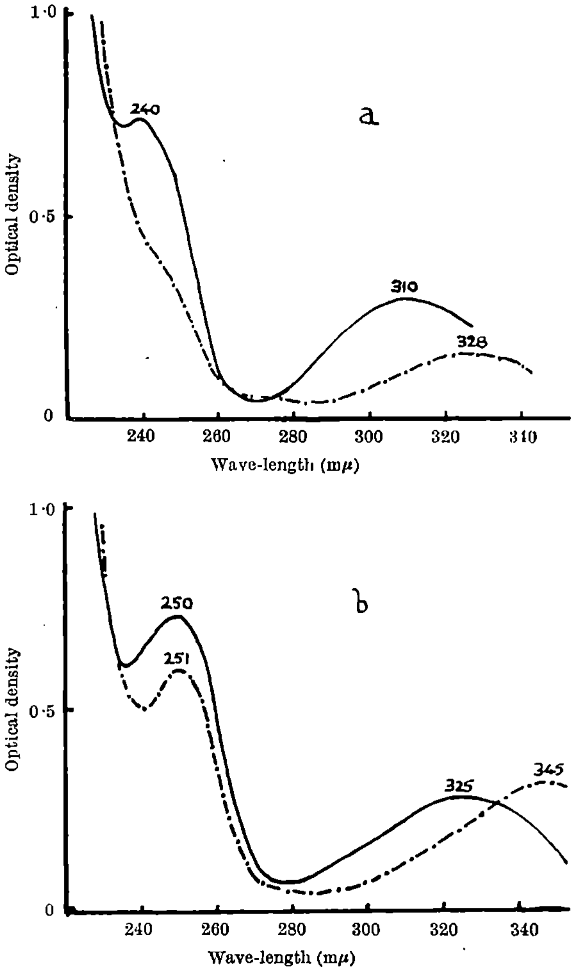

Fig. 1. Ultra-violet absorption spectra of: (*a*) anthranilic acid (10^{-4} *M*) 0·1 *M* phosphate; (*b*) experimental sample with 0·1 *M* phosphate as blank. ———, Spectrum at *p*H 7·7; —·—·—, spectrum at *p*H ∼ 2

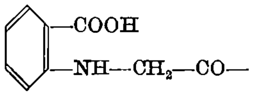
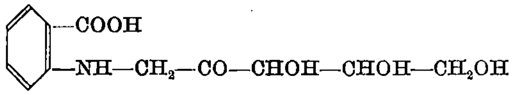
in decomposition of the compound. It has not been found possible to isolate the pure compound, but its identity has been established by the absorption spectrum, paper chromatography and by the formation of the crystalline 2,4-dinitrophenylhydrazone. The examination of the absorption spectra of a number of anthranilic acid derivatives indicated that the spectrum was consistent with the structure



The compound appears to be 1-deoxy-1-N-*o*-carboxyphenyl-ribulose.



This compound was suggested[3] as a possible intermediate in the conversion of anthranilic acid to indole and is the Amadori rearrangement product of the riboside or arabinoside of anthranilic acid. It has been prepared from both the D-riboside and D-arabinoside and although not yet isolated was readily detected on paper chromatograms by reagents such as 2,3,5-triphenyltetrazolium chloride. Concentrates of the natural and synthetic compounds readily reduced alkaline methylene blue at room temperature, a property of Amadori rearrangement products[4]. The natural and synthetic products had the same R_F value in two solvent systems and gave the same colour reactions on paper chromatograms (Table 1). The absorption spectra of the natural and synthetic compounds in ethanol and in phosphate buffer at various *p*H levels were identical.

Table 1. TESTS ON PAPER CHROMATOGRAMS SHOWING IDENTICAL RESULTS WITH THE NATURAL AND SYNTHETIC PRODUCT

Reagent	Result	Inference	Ref.
Ammonium molybdate	green-blue changing rapidly to dark blue	sugar present	6
Aniline-acetate	purple-brown	pentose	7
Phloroglucinol	dark green	keto-pentose	8
Anthrone	purple	keto-pentose	9
Alkaline 2,3,5,-triphenyl tetrazolium chloride	immediate intense red colour without heating	evidence for Amadori rearrangement products	10 4

The 2,4-dinitrophenylhydrazone of the natural product was obtained by extraction of the original compound first into ethyl acetate and then into phosphate buffer (0·1 *M*, *p*H 7·7). An acid solution of 2,4-dinitrophenylhydrazine was then added and allowed to react overnight at room temperature. The product was recrystallized from alcohol and acetone. The 2,4-dinitrophenylhydrazones of the synthetic compound and of the natural product had the same melting point (213–215°) separately and mixed. The derivatives also seemed identical on paper chromatograms. Analysis of the 2,4-dinitrophenylhydrazone of the natural product gave values for carbon, hydrogen, nitrogen and oxygen consistent with the structure proposed.

Concentrates of deoxy-carboxyphenyl-ribulose when added to minimal medium supported the growth of various mutant strains of *A. aerogenes* and *Escherichia coli* which would utilize anthranilic acid and such strains were cross-fed by strains *N*3–33 and *N*2–18 when tested by the technique described by Gibson and Jones[5]. The formation of the compound by cell suspensions was stimulated by aeration and was detectable at 1 hr. by measurement of the absorption peak at 325 mμ. For the isolation of the compound, the cell suspensions and substrates were incubated with aeration for 24 hr. Cell suspensions of *A. aerogenes N*3–33 in phosphate buffer (0·1 *M*, *p*H 7·7) readily converted anthranilic acid to deoxy-carboxyphenyl-ribulose in the presence of glucose. Details of the experiments establishing the identity of the compound will be published elsewhere.

We wish to thank Prof. S. D. Rubbo for his encouragement of this work which was aided by a grant from the Australian National Health and Medical Research Council.

Mode of Action of Chelates in protecting against *Clostridium perfringens* Toxin

IT was reported previously that ethylenediamine tetraacetic acid was capable of protecting mice against the toxin of *Clostridium perfringens*[1]. The protection thus afforded was shown to be probably due to the removal of a metallic ion or ions necessary for the activity of the toxin from the area where the toxin was acting. Inasmuch as the metallic ion or ions necessary for the action of the toxin apparently were higher in the preferential chelation series than calcium, the calcium chelate was shown to be able to protect when given systemically[2]. In this report, studies on the duration of the protection afforded by calcium ethylenediamine tetraacetic acid are presented and their implications are discussed.

The toxin, calcium ethylenediamine tetraacetic acid, and methods of administration of both of these were the same as described previously[2]. 2·5, 5 and 30 per cent solutions of calcium ethylenediamine tetraacetic acid were injected intradermally into mice; at various time-intervals thereafter the mice were injected at a different site with toxin and the deaths occurring within a 48-hr. period were recorded. The results of three typical experiments are presented in Table 1.

Table 1. DURATION OF EFFECT OF CALCIUM ETHYLENEDIAMINE TETRA-ACETIC ACID IN PROTECTING MICE AGAINST *Cl. perfringens* TOXIN

Calcium ethylenediamine tetraacetic acid injected (per cent)	Time (hr.) after injection of calcium ethylenediamine tetraacetic acid that toxin was injected. Groups of ten mice were used for each time-interval and the number that died is recorded									
	0	½	1	2	3	4	6	9	12	15
2·5	0	5	9	10	—	—	—	—	—	—
5	0	—	—	5	—	10	10	—	—	—
30	0	—	—	—	0	—	3	6	9	10

It can be seen that the protective effects of 2·5 per cent calcium ethylenediamine tetraacetic acid lasted about 30 min., that of 5 per cent about 2 hr., and that of 30 per cent about 9 hr. Inasmuch as 2·5 per cent calcium ethylenediamine tetraacetic acid is capable of completely protecting mice against the toxin and this protection lasts for but about ½ hr., it indicates that once the *Cl. perfringens* toxin is inhibited by calcium ethylenediamine tetraacetic acid there is some mechanism present in the body to inactivate it. This ability of calcium ethylenediamine tetraacetic acid to protect against the toxin is certainly not due to the inactivation of the toxin inasmuch as it has been demonstrated that the protection can be reversed by either zinc, cobalt or manganese ions[1]. These results also may explain why it was possible to render the toxin inactive in mice simply by mixing it with a small quantity of ethylenediamine tetraacetic acid[1]. If it is necessary to inhibit the action of the toxin for a short interval of time to render it non-toxic in the body, the period of time that the ethylenediamine tetraacetic acid remained at the injection site was sufficient to allow the inactivating mechanism in the body to come into play.

It was previously suggested that calcium ethylenediamine tetraacetic acid protected against the toxin when given systemically by binding the 'free' trace metals that were available in the body[2]. If this interpretation obtains, the data presented here would indicate that, although the level of 'free' trace metals is reduced to the point where the toxin is inactive with 2·5 per cent ethylenediamine tetraacetic acid, the trace metal equilibrium is restored within ½ hr. by the release of metals from depots in the body. The fact that higher concentrations of calcium ethylenediamine tetraacetic acid protect for proportionately longer periods of time suggests that sufficient calcium ethylenediamine tetraacetic acid remains in the circulation during the respective time-intervals to bind the metals that are released. An implication of these findings is that in attempts to use chelating compounds as detoxifying or therapeutic agents in other diseases a mode of administration other than that used with *Cl. perfringens* toxin will probably be necessary. In order to inhibit the growth of micro-organisms *in vivo* with agents such as antibiotics it is necessary to maintain the inhibitory level of the antibiotic until the micro-organisms are no longer active. In instances where the removal of 'free' trace metals may be inhibitory to the activities of a micro-organism *in vivo*, this condition probably would have to be maintained until the activities of the micro-organisms are suppressed to the point where they are no longer harmful to the body. A mode of administration of a chelating compound such that the level in the body is maintained sufficiently high to keep the 'free' trace metals at the requisite low level would be indicated in such instances.

In another series of experiments toxin was injected into groups of 10 mice, and at intervals of 2 hr. thereafter 5 per cent calcium ethylenediamine tetraacetic acid was injected at another site. The results of these experiments can be summarized as follows: If calcium ethylenediamine tetraacetic acid was given within 6 hr. after the injection of toxin, the mice survived; if it was given at 8 or 10 hr., the majority of mice, and all of them in some experiments, died. The median death time for the dose of toxin used was about 10 hr.; after 6 hr. all the mice were severely ill with a small percentage of deaths occurring by this time. It would appear that the action of the toxin is cumulative, and if its activity is inhibited by calcium ethylenediamine tetraacetic acid before it reaches the lethal level the mice are able to recover.

This investigation was supported by Grant *E*–1099 of the National Institutes of Health.

Adherence and Viscosity of Blood Contacting Foreign Surfaces, and the Plasmatic Zone in Blood Circulation

THE cell-free marginal zone of plasma in vessels of living animals, due to the axial accumulation of red blood cells, was already known to Haller and Spallanzani in the eighteenth century[1]. The formation of this zone was later studied by Poiseuille[1] in arteries, veins and capillaries in various species of the living animal. He found that, with increased velocity, the thickness of this layer was augmented. Recently, in the course of investigations on the flow of blood columns using a tilting viscometer (Scott Blair, G. W., personal communication), we made the following observation. If an index of human or rabbit blood, containing 0·01 mgm. heparin/ml. as anticoagulant, be permitted to flow down a large capillary tube held at varying angles from the vertical, then films of blood of varying thickness can usually be seen macroscopically on the wall after the column has passed. This finding led to investigations on the flow of varying indexes of blood, plasma and serum in glass tubes 0·5–1·4 mm. in diameter, where the Reynolds number is so small that turbulence is out of the question. We found that the adherence of fluids from moving indices in such capillary tubes can be determined by simply measuring the reduction in the length of the index after it has travelled a certain distance, and then calculating the thickness of the adherent layer. By this method, we found that this phenomenon is not limited to blood, but can also be detected when cell-free plasma or serum is used instead. Moreover, this adherence is not dependent on glass surfaces, as we found it in tubes coated with silicone, 'Lusteroid', 'Perspex' and paraffin as well.

The question now arises whether the plasmatic zone in the living blood vessels can be related to this phenomenon of adherence in tubes lined with various surfaces, and also whether adherence of fluids in capillary tubes can be found to be a general physical phenomenon. In examining how the nature of the surface affected the adherence of blood, we discovered that the velocity of flow differed markedly with all surfaces at various angles of tilt. With higher velocities, more blood adhered to glass and other surfaces.

Table 1 shows the effect of various surfaces on the velocity of flow and the adherence of blood and plasma in capillary tubes of radii ranging from 507μ to 492μ. Rabbit's heart blood and plasma from the same blood withdrawal was used in all tests. Indexes 100 mm. long were run in duplicate and triplicate along lengths ranging from 441 mm. to 426 mm. and at 20° tilt of the tube; the same glass tube being used throughout the entire series of experiments, comparative tests were run with coatings of

Table 1. FLOW AND ADHERENCE VALUES OF INDEXES. 100 MM. LONG, OF BLOOD AND PLASMA OF SAME RABBIT HEART BLOOD (0·01 MGM. HEPARIN/ML.) SAMPLE CONTACTING VARIOUS SURFACES AT 20° C. AND AT 20° ANGLE OF TILT. LENGTH OF RUN VARYING FROM 426 TO 441 MM.

Surface	Calculated radius of tube (μ)	Fluid	Flow		Adherence	
			Time (sec.)	Velocity (mm./sec.)	Vol. of index adherent (per cent)	Calculated thickness of layer (μ)
Glass	507	Blood	54·0	8·1	9·5	5·6
		Plasma	25·4	16·8	1·8	1·1
'Perspex'	492	Blood	44·8	9·6	3·8	2·2
		Plasma	23·7	18·0	2·5	1·4
'Lusteroid'	498	Blood	68·7	6·2	2·8	1·6
		Plasma	43·1	9·9	1·3	0·7
Paraffin	498	Blood	410·6	1·1	16·3	9·2
		Plasma	193·0	2·3	9·0	5·2
Silicone	498	Blood	41·0	10·4	1·5	0·8
		Plasma	21·8	19·6	0·5	0·3

'Lusteroid', paraffin wax, 'Perspex' and silicone, after control runs against the uncoated glass surface. Table 1 shows clearly that both blood and plasma indexes from the same blood withdrawal have widely varying velocities of flow depending on the surfaces with which they are in contact. For any particular surface, plasma always flowed faster than blood. As can be seen, variations in diameter of the tube due to the coatings being of different thickness cannot be made responsible for these wide divergencies in the velocity of plasma and blood indexes from the same blood sample. Nor do the anomalous flow properties of blood entirely explain these phenomena, since plasma behaves like a Newtonian fluid[2]. Table 1 also demonstrates that the amount of adherence, rather than being directly related to the velocity of the index *per se*, depends on the nature of the surface as well, with silicone exhibiting least adherence and paraffin the most in spite of the very low velocity of flow with the latter. For each surface, plasma gave relatively lower values of adherence than those of blood. The above phenomena occurred with blood–air interfaces. However, similar findings were obtained in a system without air through capillary tubes, 600 mm. long, maintained horizontally. A column of oil was merely used to act as a piston without coming in contact with the blood over the measured region of the tube.

Our results appear to be significant because: (1) Measurements of the adherence of blood and plasma have not been made thus far. The fact that blood and plasma adhere to the silicone and paraffin suggests that the well-known physical anticoagulant effect of these surfaces may be independent of the phenomenon of adherence. (2) Observations on a marginal layer in living blood vessels as well as in capillary tubes have always been related to whole blood or to suspensions of red cells in different fluids[3,4] but have never been considered for plasma without suspended red cells. It appears from our observations that the immobile layer of plasma at the blood vessel wall, as established by Poiseuille[1], is not necessarily due to a suspension of red cells, but may as well exist when plasma alone flows through a living blood capillary, for example, in plasma skimming. (3) Viscosity studies of blood and plasma have been made in the past only in glass tubes. Hence, until the nature and physical properties of the surface lining the blood vessel[5] have been established, the widely divergent values we report for blood and plasma in contact with various surfaces make it seem doubtful whether the results of all previous studies on viscosity of shed blood and plasma in glass tubes can be applied to blood and plasma circulating in living blood vessels.

Nevertheless, our observations invite new rheological studies with blood and plasma from different subjects of various species in health and disease. These findings on adherence of blood and plasma could explain why arteries and veins may differ outside of their morphological structures, because, due to the various velocities in vessels of varying diameters, one should then expect various degrees of thickness of adherent layers. Finally, our observations may throw a new light on a number of problems related to the physiology of blood circulation as well as on certain vascular disorders associated with changes in the structure of the inner or endo-endothelial lining[5] facing the lumen of the vessel.

I am indebted to Dr. G. W. Scott Blair for his helpful discussions.

This work was aided in part by a grant from the National Science Foundation, Washington.

Isolation of Reserpine from *Vinca rosea* Linn.

IN recent years considerable interest has been aroused in the use of the alkaloid reserpine in the treatment of hypertension and various mental disorders. Various plants in the family of Apocynaceae other than *Rauwolfia* have been investigated, and among them the isolation of reserpine from *Alstonia constricta*[1] is noteworthy. With the view of detecting the presence of reserpine in the plants of the Apocynaceae family we have studied the plant *Vinca rosea*. Several alkaloids have been reported from this plant: vinceine (melting point, 259–260° C.)[2], and vincaine (melting point, 250–252° C.)[3], which appears to be identical or stereoisomeric with δ-yohimbine. According to Beereboom *et al.*[4], vinceine and vincaine are indeed identical with ajmalicine, and the same authors have reported[4] the presence of serpentine (melting point, 156° C., with decomposition) and a new alkaloid, $C_{20-21}H_{26-28}N_2O_2$ (melting point, 200–201° C.) which they propose to name 'lochnerine'. Recently, ursolic acid (melting point, 280° C.)[5] has been reported present in *Vinca rosea*.

We have been able to isolate an alkaloid (melting point, 265–266° C.) from the ether-insoluble weakly basic resin of the roots of *Vinca rosea* grown in West Bengal. This is now confirmed to be reserpine by determination of the mixed melting point with authentic reserpine, as well as by the R_F values of the sample isolated, authentic reserpine and the mixture of the two. Whatman paper No. 1 and a

n-butanol/hydrochloric acid/water system were employed for chromatography.

Another alkaloidal base (melting point, 242° C., with decomposition) with R_F 0·70 (R_F reserpine 0·86) has been isolated from the same fraction. Further work on this alkaloid is in progress. Experimental details of the isolation and further work on this plant will be published elsewhere.

Auxins in Immature Maize Kernels

Ether extracts of maize-kernel pulp at *p*H 6 contain only part of the growth-promoting activity of the kernels. The juice expressed from the ether-extracted kernels is still highly active in the straight-growth test. In Table 1 the activity of the expressed juice from ether-extracted maize kernels is compared with that of an equivalent concentration of ether-extractable material.

At first, it seemed possible that these results were due to incomplete extraction of indole-3-acetic acid. To test this, ether-extracted juice was partly purified by ethanol (4 vol.) precipitation of inactive material. After removal of ethanol, the juice was acidified to *p*H 3·6 with sulphuric acid, exhaustively extracted with ether and then neutralized with barium hydroxide solution.

The activity remaining in the acid/ether-extracted juice is compared with that of the acid/ether extract in Table 2. In this experiment and the subsequent ones activity was tested by the *Avena* straight-growth test of Bentley and Housley[1].

Table 1. Effect of Maize Extracts on Wheat Coleoptiles

	Final length sections (mm.)		
	Original solution	× 10 dilution	× 100 dilution
Ether extractable fraction	11·9	19·4	14·1
Juice after ether extraction	11·2	19·2	16·5
	1 mgm./l.	0·1 mgm./l.	0·01 mgm./l.
Indole-3-acetic acid	19·2	16·5	14·1
Water controls	14·5		

Initial length of sections, 10 mm.

Table 2

	Final length of sections (mm.)		
	Original solution	× 10 dilution	× 100 dilution
Acid/ether extractable fraction	12·9	16·1	14·4
Juice after acid/ether extraction	16·2	18·7	15·8
	1 mgm./l.	0·1 mgm./l.	0·01 mgm./l.
Indole-3-acetic acid	17·3	15·8	14·3
Water controls	13·4		

Initial length of sections, 10 mm.
In this experiment, oat coleoptiles were used, as in the straight-growth test of Bentley and Housley (ref. 1).

Table 2 shows that approximately only a further 10 per cent of the activity of the ether-extracted juice can be obtained under these conditions. Indole-3-acetic acid would be completely removed by this treatment. The activity of the juice is due, therefore, to some constituent which is not indole-3-acetic acid. For an investigation of this unknown active constituent, the juice was first purified as before by ethanol precipitation. It was then evaporated to a syrup and exhaustively extracted with ether at *p*H 6.

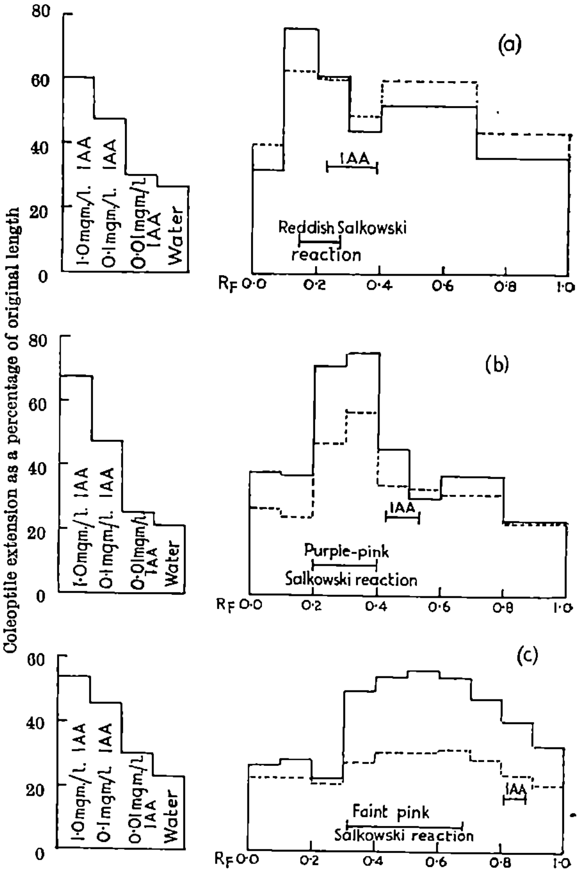

Fig. 1. Histograms of ether-extracted maize juice chromatographed in: (*a*) *n*-butanol saturated with *N* ammonium hydroxide solution; (*b*) *iso*propanol : water (4 : 1) containing a trace of ammonia; (*c*) acetone : water (1 : 1). Broken lines show activity extractable by ether after chromatography, while full lines show activity not extractable under these conditions. Assay was by the *Avena* coleoptile straight-growth test

The results in each histogram in Fig. 1 were obtained from material equivalent to 4 gm. of maize-kernel pulp. Fig. 1 shows that the activity of the juice appears at lower R_F values than does indole-3-acetic acid.

From strips of paper chromatograms run in the presence of ammonia some activity can be extracted by ether. The activity coincides with a Salkowski-reacting region on the paper. In the three chromatograms in Fig. 1, the colour of the Salkowski reaction was rather patchy and in the case of the paper run in acetone/water, very faint and indistinct. The other two papers, run in the presence of ammonia, appeared to show that a substance with a purple Salkowski reaction was present. At slightly greater R_F values, though not completely separated from the purple zone, there was a reddish Salkowski reaction.

The general impression obtained was that in ammoniacal solvents a substance with a purple Salkowski reaction was giving rise to a substance with a red Salkowski reaction and a greater R_F value. The indistinctness of the spots was thought to be due to the effect of large amounts of other constituents present.

A further concentration of the juice was made. Juice equivalent to about 200 gm. pulped maize kernels was partly purified by ethanol precipitation followed by exhaustive ether extraction as previously described. The syrup (25 ml.) obtained after evaporation of the ethanol was mixed with anhydrous sodium sulphate (100 gm.) and the mixture stirred with absolute ethanol. The ethanolic extract was filtered off and the process repeated three more times. The combined ethanolic extracts were evaporated to a small volume. Fig. 2 shows the histogram obtained when one-eighth of the syrup was chromatographed in *n*-butanol saturated with water. A tank completely free from ammonia was used.

The peak of activity corresponded to a region with a purple Salkowski reaction. After treatment of the paper with *N* sodium hydroxide solution, the same region no longer gave a purple Salkowski reaction. Instead, there was a red Salkowski reaction exactly like that given by indole-3-acetic acid. This red colour was more intense than the original purple, and had a greater spread of R_F value. Before sodium hydroxide treatment, no zone of the paper gave any trace at all of a red Salkowski reaction.

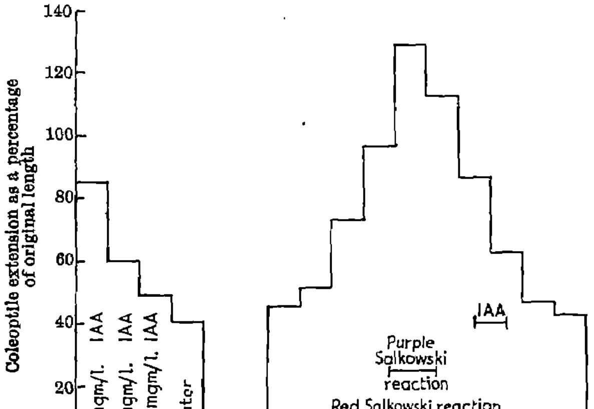

Fig. 2. Histogram of maize juice concentrate chromatographed in water-saturated *n*-butanol and tested by the *Avena* coleoptile straight growth test

Both the red and the purple Salkowski reactions appeared to be given by two overlapping spots, indicating that the activity is not due to one compound only. A purple Ehrlich reaction given by the same region of the chromatogram also appeared to result from two overlapping spots.

The high activity relative to the indole-3-acetic acid controls shown in Fig. 2 has been noted in other experiments, but is not always reproducible.

These results were obtained with extracts from a Himalayan strain of maize, and also from a commercial variety, Northern Cross. The Salkowski and Ehrlich tests were carried out by the methods of Stowe and Thimann[2]. This work is continuing, and a further report will appear later. We wish to thank Profs. S. C. Harland and E. R. H. Jones for facilities and also Mrs. V. Shaw for carrying out biological tests.

Influence of Introduction of a Fructosyl Group into Galactosylglucoses on their β-Galactosidase-inducing Activity

INTRODUCTION of a fructose group at the reducing carbon position of melibiose (to form raffinose) is known to abolish the β-galactosidase-inducing capacity of this α-galactoside in *Escherichia coli*[1,2]. The question arises whether this effect of the fructose group applies also to induction effected by β-galactosides. A study was therefore made of the β-galactosidase-inducing capacity of an homologous β-galactosidic oligosaccharide pair, namely, the pair lactose and α-lactosyl-β-fructofuranoside[3]. This last sugar, which will be referred to as 'lactsucrose', has a terminal β-galactosidic linkage, and is readily cleaved to galactose and sucrose both by *E. coli K*–12 β-galactosidase in solution and by a washed suspension of lactose-induced cells of this strain (Table 1). It proved, however, to be a negligible inducer of the β-galactosidase. Thus, the relative behaviour of lactose and lactsucrose resembles that of melibiose and raffinose in respect of the capacity to induce β-galactosidase in *E. coli K*–12. Moreover, it has also been shown recently that raffinose can be metabolized by melibiose-induced cells[6]. This indicates that raffinose is able to penetrate such cells. The cleavage of lactsucrose by lactose-induced cells indicates similarly that lactsucrose can enter these cells.

It is thus evident that the introduction of a fructosyl group at the reducing carbon of lactose results, as with melibiose, in a marked diminution of the ability of the disaccharide to serve as inducer of the β-galactosidase system. Such behaviour can be

Table 1. ACTIVITY OF *E. coli* β-GALACTOSIDASE TOWARDS LACTSUCROSE

Sugar in growth medium*	Inducer†	β-Galactosidase activity‡		Hydrolysis of the β-galactosidic linkage‖	
		Washed cells	Cell extract§	Lactose	Lactsucrose
Glucose	—	0·0	0·5	–	–

Lactose	—	12·4	240·0	+	+

* Growth was conducted for 24 hr. in '56' synthetic medium containing 2 per cent sugar (ref. 1).

† Washed cells (in a concentration equivalent to 5 mgm. dry weight/ml.) were incubated 5 hr. at 37° C. in an induction medium (ref. 4) containing 0·02 *M* inducer.

‡ Expressed in terms of units of hydrolysis of *o*-nitrophenyl-β-galactoside (ref. 5) per mgm. dry weight.

§ Cells were mechanically disintegrated with glass beads in a Mickle vibrator. The supernatant solution given by centrifuging for 15 min. at 8,000*g* served as the enzyme solution.

‖ (+) indicates > 50 per cent and (–) < 2 per cent hydrolysis of substrate, both by cells and by their extract. The reaction mixture contained 0·1 *M* sugar, 0·05 *M* phosphate buffer *p*H 7·0 and fresh cells (5 mgm. dry weight/ml.) or enzyme solution (1 mgm. dry weight/ml.). After incubation at 37° C. for 6 hr. products of hydrolysis and decrease in the initial amount of substrate were observed by methods of paper chromatography and reducing sugar determination (ref. 3).

attributed to inability of the trisaccharide to reach the site of β-galactosidase induction, and/or a lack of inductive capacity proper. The permeation step is known to be controlled by a specific inductive system[7-9]. It is conceivable that raffinose and lactsucrose are incapable of inducing the permeation system, whereas cells induced by lactose possess it and hence are also penetrated by trisaccharides.

I wish to thank Prof. S. Hestrin for helpful advice.

Demonstration of Some 'Masked' Lipids in the Oocytes of *Chrotogonus trachypterus* with Sudan Black *B* and Phenol 'Unmasking' Techniques

SUDAN black *B*, in spite of being the most specific and vigorous dye for the demonstration of lipids in tissue sections[1,2], has its limitations[3,4]. The cell inclusion believed to be lipid may not be coloured with sudan black *B*, because: (1) some lipids (like phospholipids) may escape from the tissue into the fixative by the process of emulsification[2,3]; (2) the lipids present have a high melting point and thus remain 'solid' in tissue sections[3]; or (3) the lipids present are 'masked' by proteins or other substances.

All these difficulties have been experienced in this laboratory during the histochemical investigation of the lipids in the oocytes of a number of animals[5]. The first one can always be eliminated by fixing the tissue in fluids containing free calcium ions[3] (like formaldehyde–calcium of Baker[2]), and by post-chroming; while the second difficulty can be overcome to a great extent by using the dye at 60° C. for longer periods (say 30 min.). But the lipids still remaining uncoloured have either a melting point much higher than 60° C. (for example, cholesterols and cholesteryl esters), or they may be 'masked'. The cholesterols and cholesteryl esters can always be detected by using specific histochemical tests[1,4,6]. It is the presence of 'masked' lipids which has troubled many previous workers.

Although the 'masked' lipids may be 'unmasked' and thus coloured with sudan black *B* by a simple treatment of the tissue sections with the various fat-solvents like acetone, ether, etc., which 'unmask' the lipids not removed by these solvents[5,7,8], yet such treatments are inadequate to 'unmask' the lipids in larger lipid bodies for which some special unmasking techniques recommended by Ciaccio[9] must be employed.

In the oocytes of *Chrotogonus* it has been found that a large number of sudanophil lipid spheres constantly give a 'ringed' or 'crescentic' appearance (that is, a dark sudanophil sheath enclosing a completely non-sudanophil core of various sizes) even when the sections of the material fixed according to the formaldehyde–calcium/postchroming technique[2] are coloured with sudan black *B* in propylene glycol[10] at 60° C. for 1 hr. These bodies give a completely negative reaction to all the tests for cholesterol and its esters[1,4,6], in spite of repeated attempts. This shows that if lipids are present in the core they must be 'masked'.

Ciaccio's[9] various techniques were tried to 'unmask' them. The methods, which include an 'unmasking' fixative, namely, Da Fano, Ramon y Cajal with or without potassium dichromate, did not prove successful. Of the two special 'unmasking' agents recommended, trypsin also was not so successful, but phenol gave excellent results. The material fixed in formaldehyde–calcium for 6 hr. was treated with 1 per cent phenol solution at 37° C. for 24 hr. The gelatin sections of this material when coloured with sudan black *B* did not reveal any 'ringed' or 'crescentic' appearance of the lipid bodies, which now coloured uniformly blue-black. This shows clearly that the lipids present in the uncoloured cores of the 'crescentic' and 'ringed' lipid spheres in the oocytes of *Chrotogonus* were 'masked' ordinarily by proteins; the presence of the latter is shown by the stainability of these lipid bodies with mercuric–bromophenol blue[11].

The kindness of Dr. S. Bradbury, Cytological Laboratory, Department of Zoology, University of Oxford, for sending the details of Ciaccio's techniques not available here, is gratefully acknowledged.

Influence of Time on the Reversible Association between Large Molecules: the Collagen System

It is increasingly evident that reversible interactions between macromolecules underlie many important biological functions; the actomyosin system is a classical example. Time-related changes in association between large molecules, which give rise to altered solubility and tensile strength (often associated with increased order), are well known to polymer chemists. It is suggested here that biological systems which rely on controlled intermittent association between specific macromolecules may, by increasingly long periods of association, become fixed in an irreversible or very slowly reversible state, resulting in impaired or lost function.

This communication reports an example of time-related changes in solubility of fibrils formed in relatively homogeneous solutions of collagen. Cold neutral salt extracts of fresh skin from growing animals contain collagen in solution which may be precipitated as an opaque gel composed of cross-striated fibrils, characteristic of the native tissue, by warming to 37° C.[1]. Purified collagen isolated from such extracts behaves in like manner[2]. Dilute acetic-acid extracts of collagen dialysed against neutral buffers can be gelled in a similar way. The effect of certain electrolytes and non-electrolytes on the rate of heat gelation has been briefly described[3].

It was observed in the course of these studies that the opaque collagen gels would occasionally be re-dissolved on cooling in the refrigerator. Fessler[4] has independently reported that one fraction of purified collagen obtained from rabbit skin by neutral salt extraction would, after precipitation by warming, redissolve on cooling. The investigations reported here revealed that one factor determining whether or not a gel would dissolve on cooling was the time it remained at the higher temperature.

Clear viscous solutions of collagen were prepared from calf dermis by extraction with 0·5 *M* acetic acid and dialysis consecutively against phosphate buffer, *p*H 7·6, $\Gamma/2 = 0{\cdot}4$, and sodium chloride, $\Gamma/2 = 0{\cdot}45$. Other samples were similarly prepared at physiological ionic strength and *p*H. These solutions are 'homogeneous' electrophoretically and in the ultracentrifuge. Partial composition of the dissolved collagen was reported earlier[3].

When warmed to 37° C. the opacity of the rapidly formed gel increased with time along a sigmoid curve as observed in a 'Klett' photoelectric colorimeter (No. 540 filter). Opacity, in this system, was a direct function of precipitated protein sedimentable at 80,000*g* for 1 hr. This was demonstrated by analysis of the supernatant solution and weighing of the dried, salt-free precipitates. Series of samples of the two neutral solutions described above were allowed to stand in a water-bath at 37° C. for varying time-intervals ranging from 10 min. to 48 hr. after reaching maximum opacity. At the end of each period the tubes were transferred to an ice-bath and the fall in opacity was measured at 1-min. intervals in the colorimeter. After the rate of decrease in opacity had diminished nearly to zero the samples were centrifuged cold at 80,000*g* for 1 hr. and the collagen-content of the supernatant solutions was determined by hydroxyproline analysis, and the dry salt-free precipitates were weighed. Results of a typical experiment using a collagen solution, sodium chloride 0·14 ionic strength buffered to *p*H 7·4 with 0·008 *M* phosphate, are shown in Fig. 1. On cooling a gel for 10 min. after it had reached maximum opacity at 37° C., there was a fairly prompt fall in opacity, levelling off at about 40 per cent of the control value. After 48 hr. of incubation, less than 10 per cent reduction in opacity was observed on cooling. The same phenomenon in a greater degree occurred in solutions of 0·45 ionic strength. The loss in opacity on cooling after 10-min. incubation was 100 per cent and after 48 hr. of incubation was less than 10 per cent.

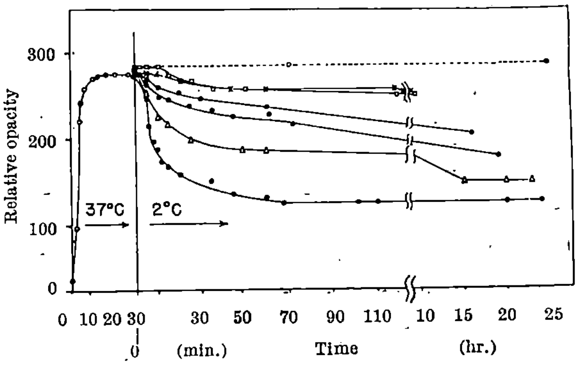

Fig. 1. Effect of cooling to 2° C. on the opacity of collagen gels incubated at 37° C. for different periods of time. Reading from the lowest curve upward: ●, 10 min.; △, 1 hr.; ◒, 3 hr.; ◓, 6 hr.; □, 24 hr.; ×, 48 hr.; ○ - - - - ○, 56 hr. (control, not cooled). Starting solution contained about 0·2 per cent calf-skin collagen dissolved in cold 0·14 *M* sodium chloride buffered with phosphate to *p*H 7·6

This phenomenon was also observed in cold saline extracts of fresh guinea pig skin which contained relatively high concentrations of a collagen fraction thought to be the precursor of the characteristic tissue fibrils.

Changes in solubility of the gels at acid *p*H as a function of time of previous incubation at neutral *p*H were also investigated. Between one and two weeks of incubation at 37° C. were required for the collagen gels to become almost completely insoluble in cold citrate buffer at *p*H 3·5.

It is improbable that the system reported here required interaction with non-collagenous components or enzymes. It is suggested that the increasing degree of irreversibility may result from the action of Brownian movement, allowing the associated molecules to find their most stable and sterically matched fit, thus permitting the establishment of more intermolecular cross-links.

The results of this study suggest the possibility that increasing time of association between biological high polymers may, at least in some instances, be contributing factors to ageing changes in structure and function in the organism.

This work has been supported by Grant No. *A* 90 (*C*7) of the Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service, and an Established Investigatorship of the American Heart Association.

Isomorphous Replacement in the Kaolin Group of Minerals

It has been customary to classify the groups of layer silicate minerals as trioctahedral or dioctahedral according as all the octahedral ion sites in the lattice are occupied, or only two sites out of three. Virtually all minerals in the layer silicate groups fall clearly into one of these two divisions, the number of octahedral sites per unit cell occupied being usually nearly round numbers.

In the kaolin group the purely aluminous minerals, kaolinite, dickite and nacrite are dioctahedral members. Hallimond[1,2], Brindley[3,4] and Brindley and Youell[5] have shown that the chamosite present in sedimentary ironstones is a member of the kaolin group and that its molecular formula is very close to a trioctahedral structure, typically 2·9 octahedral sites out of every 3 being occupied by iron, magnesium or aluminium. There has been considerable recent evidence from microradiography[6], and chemical analysis and X-ray diffraction[7] that the composition of chamosite can vary between wider limits than had been supposed originally. Previous attempts to classify chamosite[2] have considered the Pauling structure for the kaolin and chlorite groups, trioctahedral members of which have a common empirical formula $X_3(\mathrm{SiAl})_2\mathrm{O}_5(\mathrm{OH})_4$ [X = Fe,Mg,Al....] representing half the unit-cell content of kaolin, and a quarter of the unit cell of chlorite. Agreement with this structure has not, in general, been very good. Other methods of classification[2,8] have used the oxide ratios in the formula of chamosite originally suggested by Zalinski[9]. This method has no justification from a structural point of view, but has indicated that for most chamosites derived from sedimentary ironstones the numbers of silicon and aluminium atoms in the structure are very nearly equal, although RO (where R = Fe or Mg) is often substantially lower than in Zalinski's formula.

It has recently been possible[10] to obtain a complete analysis of a chamosite from the chamosite–kaolinite (top) beds of the Northampton sand ironstone formation at Wellingborough. There were strong indications[6,7] that this specimen was particularly low in iron content, and analysis has confirmed these. The low iron content could not be accounted for by simple admixture of kaolinite. The structural formula, evaluated on a basis of 9(O + OH) ions in the formula, was :

$$\underbrace{\mathrm{Al}_{1\cdot09}\,\mathrm{Fe}^{2+}_{1\cdot30}\,\mathrm{Fe}^{3+}_{0\cdot12}\,\mathrm{Mg}_{0\cdot16}}_{2\cdot67}\,(\mathrm{Si}_{1\cdot59}\,\mathrm{Al}_{0\cdot41})\,\mathrm{O}_{5\cdot15}\,(\mathrm{OH})_{3\cdot85}$$

This compares with the formula of a chamosite from the Main Ironstone beds of the same formation[5] at Corby :

$$\underbrace{\mathrm{Al}_{0\cdot85}\,\mathrm{Fe}^{3+}_{0\cdot01}\,\mathrm{Fe}^{2+}_{1\cdot83}\,\mathrm{Mg}_{0\cdot23}}_{2\cdot92}\,(\mathrm{Si}_{1\cdot33}\,\mathrm{Al}_{0\cdot67})\,\mathrm{O}_{5\cdot02}\,(\mathrm{OH})_{3\cdot98}$$

It is clear that (*a*) the RO value is much lower than for the main ironstone chamosite, even when all iron is included as RO (1·58 against 2·07) ; (*b*) the occupation of octahedral sites is so low (2·67 against 2·92) that the Wellingborough specimen can scarcely be regarded as properly trioctahedral ; and (*c*) the Si/Al ratio is still nearly 1. Replacement of tetrahedral silicon by aluminium is low, whereas the amount of octahedral aluminium is high ; this represents a deviation towards the kaolinite composition.

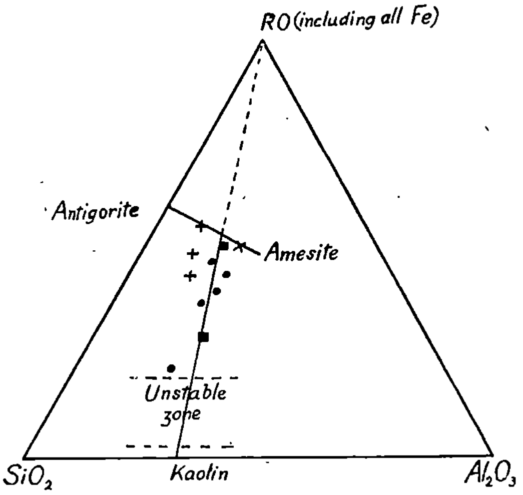

Fig. 1. Chamosite analyses: ■, present work; ●, Taylor; +, acid-extraction method (low aluminium); ×, lateritic origin (high aluminium)

This formula is so far from the Pauling structure composition that it seems necessary to seek some other method of classifying chamosite. It would appear that isomorphous replacement of iron and aluminium occurs between chamosite and kaolinite over a wide range of compositions, and that structures intermediate between dioctahedral kaolinite and the trioctahedral 'normal' chamosite are possible. Following Taylor[8], it is useful to present chamosite analyses as a triangular composition diagram (Fig. 1) based on $\mathrm{SiO_2}$, $\mathrm{Al_2O_3}$, and RO (the latter including all iron calculated as ferrous). On the basis that the silicon–aluminium ratios in chamosite are nearly 1, a line joining RO with the kaolinite formula ($2\mathrm{SiO_2}$, $\mathrm{Al_2O_3}$) should include all possible intermediates between chamosite and kaolinite. The chamosites from Wellingborough[10] and Corby[5] lie very close to this line and five analyses by Taylor[8] (although in some cases obtained by difference from materials containing only 30 per cent chamosite) are also in reasonable agreement with this line. Analyses quoted by Hallimond[2] and Taylor[8] made by the acid-extraction method (which tends to give low values for the aluminium content of the mineral) are well on the silica-rich side of the line, whereas a chamosite of lateritic origin[4] is, as may be expected, divergent in the aluminium-rich direction. Work by Grimshaw *et al.*, and Brindley, Robertson and Mackenzie has shown that a very small amount of substitution in the kaolinite lattice produces considerable disorder in the mineral. Very small amounts of iron present in place of aluminium produce a highly disordered fireclay and not a well-ordered kaolinite. This is in agreement with the much larger size of the ferric ion compared with the aluminium ion.

At the other end of the series, an iron-rich chamosite agreeing fairly well with the Pauling structure (as represented by the amesite–antigorite line) contains a high proportion of large ferrous and magnesium ions. Considerable substitution of small aluminium ions in the octahedral positions may occur without disrupting the lattice, although appreciable disorder is apparent in X-ray photographs of chamosites with high octahedral aluminium values.

There appears to be a zone which is structurally unstable for which no specimens have yet been found. A substantial part of the chamosite–kaolin series is, however, represented by actual specimens, and it is suggested that this series forms a sounder basis for classification than the Pauling formula composition or Zalinski's oxide-ratios.

Thanks are due to Dr. E. Cohen, of the British Iron and Steel Research Association, and Prof. J. H. Taylor for specimens. A full account of this work will be published later.

Dynamics of Chain Molecules in Dilute Solutions, with Special Reference to Non-Newtonian Viscosity

SEVERAL aspects of the phenomena appearing when chain molecules in dilute solutions are subjected to a velocity field seem to be satisfactorily explained by the theory which I have recently proposed[1]. In particular, the correct shape of the curve giving tan α (initial slope of extinction angle curve, as resulting from flow birefringence measurements) as a function of η_0 (viscosity of solvent) has been obtained; quantitative agreement has been observed between the calculated and the measured slope of the asymptote to the preceding curve, in the case of polystyrene; the correct dependence on molecular weight of the internal viscosity term B in tan α has been obtained (proportionality of B to the molecular weight, as established experimentally by Leray for polystyrene[2]); and finally it has become possible to understand some of the characteristics of non-Newtonian viscosity.

Furthermore, an expression of the intrinsic viscosity for molecules of low internal viscosity, valid in a wide range of velocity gradients, has recently been obtained[3]; this expression contains three molecular parameters which can all be determined experimentally: the molecular weight M, the zero gradient intrinsic viscosity $[\eta]_0$, and the ratio, B/M, which is characteristic of each kind of polymer.

These last results have been compared with the non-Newtonian viscosity measurements of Čopič[4] on a series of polystyrene fractions. The theoretical curves giving the intrinsic viscosity $[\eta]$ as a function of the velocity gradient G were computed, using the values of M and $[\eta]_0$ given by Čopič and the value of B/M deduced from flow birefringence measurements of Leray[2]. The agreement, though not perfect, is quite significant[3].

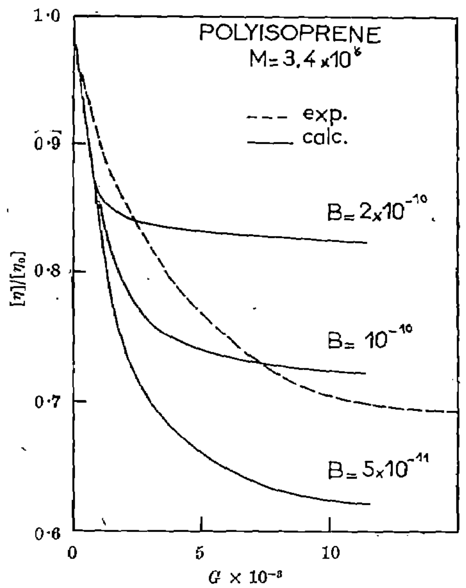

Fig. 1

Here, I wish to make the comparison with the measurements of Golub on a series of polyisoprene fractions[5]. No flow birefringence data are available in this case; therefore it is not possible, as in the case of polystyrene, to compute the $[\eta]$ versus G curves from the theory, not using any adjustable parameter.

I have first computed three theoretical curves for polyisoprene 1c, giving B/M respectively the values 5×10^{-11}, 10^{-10}, 2×10^{-10}. In Fig. 1 it can be seen that a reasonable agreement with the experimental curve is obtained taking $B/M = 10^{-10}$.

The theoretical curves for the samples 1a, 3a and 3b have then been computed (taking B/M as a constant). The comparison with the experimental curves is made in Fig. 2 for the samples 3a and 3b: the agreement is quite good. For sample 1a the agreement is of the same type as for 1c; the curves relative to 1a are not represented here.

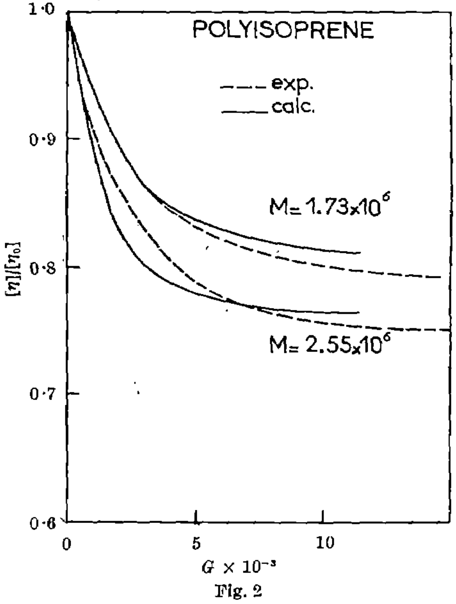

Fig. 2

Deviations like those observed on Fig. 1 are not surprising, since the conditions of validity of the theory are not rigorously fulfilled (the internal viscosity of polyisoprene is a little too high), and since the theory becomes insufficient when G approaches infinity.

Thus the theory explains a large number of facts, and is well suited to describe many essential features in non-infinitely small gradients. It is hoped that new possibilities of the hydrodynamic methods will follow; it is already possible to obtain the parameter B, and therefore the internal viscosity of the molecule, from one single $[\eta]$ versus G curve.

A Survey of Terrestrial Craters

The domination of the Moon's surface by circular crater-like features raises the question as to whether this is a phenomenon peculiar to the Moon or whether it has significance for the solar system as a whole, including the Earth. The latter view has been urged by Baldwin[1] and others[2,3], who conclude that the lunar craters are due to meteorite impact and that the Earth has suffered a similar bombardment of which known meteorite craters are the residual evidence.

Baldwin's correlations are on the whole rather convincing, but the data on terrestrial meteorite craters available at the time his work was done were statistically less impressive than might be desired. Although widely distributed over the Earth, specimens being found in Europe, Asia, Africa, Australia and North and South America, only 17 craters or clusters of craters were known prior to 1950. While some of the clusters contained many pits, they were for the most part small, and only ten individual craters were known to be more than 100 metres (330 ft.) in diameter, the limit of size which can be observed on the Moon (Kuiper, G. P., private communication). In addition, all these craters belong to a recent geological epoch, whereas there is evidence pointing to a wide distribution of ages among lunar features.

Discoveries made during the past seven years have provided appreciable extensions to the data in the directions of numbers, diameters and ages of craters. These include the Chubb or New Quebec Crater, 3·4 km. diameter (Recent)[4], the Talemzane Crater, 1·8 km. diameter (Late Pliocene or early Quaternary)[5], the Brent Crater, 3·7 km. diameter (Early Paleozoic)[6], the Holleford Crater, 2·4 km. diameter (Early Paleozoic)[7] and the crater at Deep Bay, Saskatchewan, diameter 13·7 km. (Late Mesozoic)[8]. In addition, two large circular arcs have been noted in Canada, the Belcher Islands arc in Hudson Bay, 400 km. diameter, and the arc containing Prince Edward Island and outlined by the neighbouring coasts of Nova Scotia and New Brunswick[9], 300 km. diameter, both of which may be due to meteorite impact.

Most of the more recent crater discoveries have been made as a result of systematic studies of aerial photographs, and it seems reasonably certain that some of the most interesting objects would have remained in obscurity for a long time if these photographs had not been available. It is the purpose of this communication to suggest that the wide aerial photographic coverage which now exists throughout the world represents an opportunity to make what could be a decisive contribution to this branch of astronomical and geophysical science. The equipment necessary for studying aerial photographs is very modest, and a determined worker can cover a relatively large area of country in a short time. If systematic searches could be initiated in many countries, it would be reasonable to expect a trend to emerge which would go far to settle the still unsolved problem of the relationship between terrestrial meteorite craters and the astonishing array of circular objects covering the surface of the Moon.

Etch Figures on Sodium Chloride Crystals

GYULAI and his co-workers have for some years been investigating the properties of alkali halide crystals. In the course of etching sodium chloride and rock salt crystals I have made some observations which may throw light on the dislocations supposed to exist in real crystals.

Cleaved crystals of sodium chloride were etched in alcohol mixed with a small quantity of formaldehyde. After etching for a few minutes, that part of the sample which was in contact with the container revealed etch-figures, shown in Figs. 1 and 2. The examination and photography of these samples was carried out in transmitted light, with an '*L*-Stative' Zeiss microscope. The etch-figures are most instructive. The growth layers, and the lamellar structure of the crystals show up clearly. On the single growth steps right- and left-handed spirals and their various combinations have become visible. The single spirals are squares with rounded corners, their orientation corresponding with the cubic edges of the crystal. The direction of observation was (001).

The photomicrographs give a detailed picture of the etched (001) plane. The etch-figures are similar to those obtained by A. R. Verma[1] on silicon carbide. Voltava and Amelinckx[2] obtained spiral figures on the surfaces of sodium chloride crystals by thermal etching. The spirals and their combinations obtained by the use of etching reagents are, however, clearer,

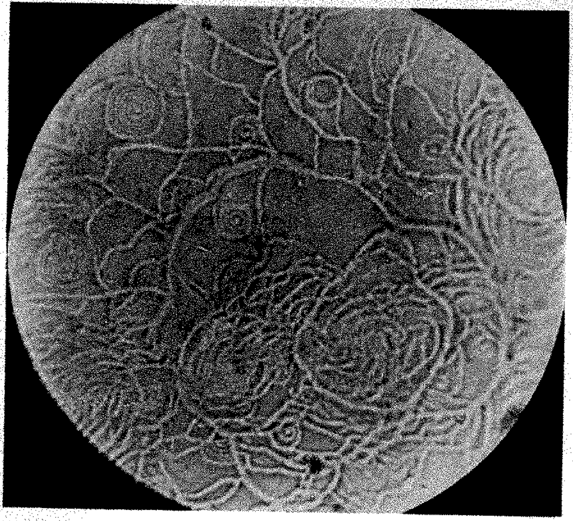

Fig. 1. Surface of a sodium chloride crystal after etching in alcohol +formaldehyde for 30 min. × 500

more easily obtained and are durable in dry air. The etching method described here may be applied to synthetic as well as to natural crystals, and with appropriate modification may also be used for potassium chloride crystals. Investigations in this direction are being carried out.

Another observation has been made on deformed crystals of sodium chloride. Synthetic blocks of sodium chloride a few millimetres in length and diameter were slightly deformed by bending. After etching a deformed crystal for 0·1 sec. in glacial acetic acid very regular etch-pits were obtained on every side of the sample. The etch-pits are regular, square-shaped concave pyramids. These observations were also made with a Zeiss '*L*-Stative' microscope, with a magnification of about 100, in transmitted light. The etch-pits are located on the (001) plane as seen from the direction of the bending axes on the (110) slip planes. The etch-figures are grouped in more or less dense strips. It is, however, unnecessary to deform the sample, because cleavage itself initiates slips, which seems to be unavoidable. When preparing the sample by cleaving it on six sides, deformations are produced in the crystals. Thus every surface examined contained systems of two perpendicular bands and two bands inclined at an angle of 45° to the (100) direction. These bands consist of square etch-pits and in some cases they may be observed individually. According to the observations of W. Dekeyser, J. J. Gilman and W. G. Johnston[3] and others, such etch-pits originate at the ends of dislocations emerging on the surface. Taking into consideration the potential mobility of the dislocations, the network of the 45°-bands may be interpreted as containing edge-dislocations, and the 90°-orthogonal network as containing screw-dislocations. Etching in glacial acetic acid provides a very quick method for investigating grain boundaries. After a short etching time, the grain boundary becomes readily visible as a region densely packed with distorted etch-pits.

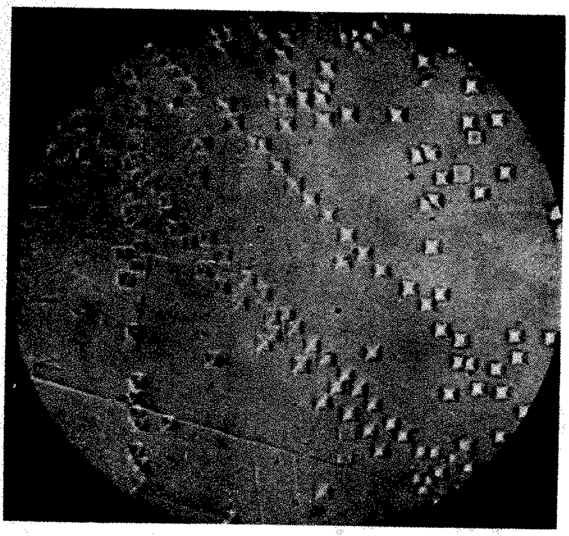

Fig. 2. Cleaved surface after etching for 0·1 sec. in glacial acetic acid. × 350

It is interesting to observe that the edges of the cleavage lamellæ are attacked by the reagent only after a considerably longer period.

Further investigations are in progress.

Relativistic Aberration Formula

It has been stated that "the relativistic aberration formula, $\tan\theta' = \sin\theta(1 - v^2/c^2)^{1/2}/(\cos\theta + v/c)$ . . . deviates from the equation . . . of the ether theory by quantities of second order only, a deviation which is negligible compared with the present accuracy of the measurements"[1]. The aberration is also referred to as a "displacement, $\theta - \theta'$"[2].

The angles θ, θ', however, which appear in the formula, are measures in different frames of reference, and subtraction of them is meaningless observationally. The 'displacement', as measured by the observer, would be $\theta - \theta''$, where θ, θ'' give, respectively, the apparent and actual directions of the source in the frame of the observer, simultaneously for him. But in that frame, since the source has moved vt while the ray has moved ct, t being the time of transit from source to observer, we have $\tan\theta'' = \sin\theta/(\cos\theta + v/c)$, exactly as in the classical theory for an observer at rest in the ether. It is obvious, in fact, that there would be no deviation between the classical and relativity theories for such an observer, since no transformation of co-ordinates is involved.

If it is the source which is at rest in the ether, the classical theory requires us to superpose on the picture relative to the observer an ether drift of v in the direction of the source's velocity. The velocity of the light-ray being now approximately $(c + v\cos\theta)$ relative to the observer, by the same argument we find $\tan\theta'' = \sin\theta/\{\cos\theta + v/(c + v\cos\theta)\}$, which gives a second-order deviation between the theories amounting to twice the deviation now accepted. In general, with an ether drift of V (not commensurate with c) away from the observer, the deviation is $(vV/c^2)\tan\theta$ instead of $\frac{1}{2}(v^2/c^2)\tan\theta$, as given by the accepted formula.

Random Time

If the point of the hand of a clock moves along the circumference of the unit circle with constant angular velocity ω, then the time measured is determined by the position:

$$\exp i\omega t \tag{1}$$

This formulation depends, however, on the abstraction of a 'uniform time', a concept which, after Mach's critique, fails to be meaningful and cannot be made legitimate even if a built clock is replaced by a clock determined by the gyrations of the Earth (or, for that matter, of a galaxy). Clearly, the conceptual difficulty remains unaltered if, instead of astronomical clocks, recourse is had to electron clocks—those supplied by electromagnetic or spectroscopic measurements.

Actually, the irreducibility of the vague notion of what is the 'uniformity' of the independent variable t (classical or relativistic) is not merely an epistemological issue. For 'time' can be defined only by measurements, and the measurements can be carried out only on the movements of instruments (clocks, planets, electrons), whereas every physical object and its observations are necessarily subject to imperfections or, at best, to statistical fluctuations. What is more, the same holds for every physical law as well (by physical law we understand here differential equations in which t is an independent variable). The object of this communication is the harmonic analysis of the simplest (and, in a certain mathematical sense, uniquely determined) model of the statistical fluctuations of 'time' itself.

If $\mathrm{f}(t)$ is defined for $-\infty < t < \infty$ as a function for which the auto-correlation:

$$F(t) = \lim_{T\to\infty} \frac{1}{2T}\int_{-T}^{T} \mathrm{f}(t+s)\bar{\mathrm{f}}(s)ds \tag{2}$$

exists as a continuous function for $-\infty < t < \infty$ (the bar refers to complex conjugation), then $F(t)$ is necessarily of the form[1]

$$F(t) = \int_{-\infty}^{\infty} \exp itu d\varphi(u) \tag{3}$$

where $\varphi(u)$ is a certain bounded function satisfying $d\varphi(u) \geqq 0$.

If $\mathrm{f}(t)$ is chosen to be the function (1), then it is identical with $\mathrm{f}(t+s)\bar{\mathrm{f}}(s)$ for every s. Hence (2) shows that $F(t) = \mathrm{f}(t)$ if $\mathrm{f}(t) = \exp i\omega t$, which means, by (3), that the distribution function φ (representing the spectral energy) is a Dirac distribution, consisting of a single saltus: $\varphi(u) = 0$ for $-\infty < u < \omega$ and $\varphi(u) = 1$ for $\omega < u < \infty$. Clearly, the statistical fluctuations of time, referred to above, will have to dissolve the resulting infinite concentration (represented by a discrete, sharp spectral line) at $u = \omega$. Let the fluctuations be realized as follows:

Add to the t of (1) the function $ax(t, \alpha)$, where a denotes a positive constant and $x(t, \alpha)$ is a normalized function as defined in the theory of differential space[2]. Then, since (1) or $\mathrm{f}(t) = \exp(i\omega t)$ is replaced by:

$$\mathrm{f}(t, \alpha) = \exp(i\omega\{t + ax(t, \alpha)\}) \tag{4}$$

where x is real-valued and α is a parameter (to be averaged over the interval $0 \leqq \alpha \leqq 1$), the function (2) becomes:

$$F(t, \alpha) =$$

$$\exp i\omega t \lim_{T\to\infty} \frac{1}{2T}\int_{-T}^{T} \exp(i\omega a\{x(t+s, \alpha) - x(s,\alpha)\})ds \tag{5}$$

Here α is a point (not contained in a set of measure zero) on the integration-range of differential space.

In view of the Gaussian definition of measure in differential space, it can readily be concluded from the ergodic theorem[3] that, for almost all values of α, the time-average which multiplies $\exp i\omega t$ in (5) is identical with the corresponding space-average in differential space, and, therefore, with the integral

$$\int_{-\infty}^{\infty} \exp(i\omega av)(2\pi|t|)^{-1/2}\exp(-\tfrac{1}{2}v^2/|t|)dv$$

But this is Laplace's integral, the value of which is known to be $\exp(-\frac{1}{2}\omega^2a^2|t|)$. If this evaluation is substituted in the representation (5) of the function $F(t, \alpha)$, a function which, being independent of α (for almost all α), can now be denoted by $F(t)$, and if the result is compared with (3), it follows that:

$$\int_{-\infty}^{\infty} \exp itu\, d\varphi(u) = \exp i\omega t \exp(-\tfrac{1}{2}\omega^2a^2|t|)$$

This can be written in the form

$$\int_{-\infty}^{\infty} \exp itu\, d\varphi(u - \omega) = \exp(-\rho|t|) \tag{7}$$

where

$$1/\rho = 2/(\omega a)^2 \tag{8}$$

Finally, the integral of $\exp(itu)/(1 + u^2)$ over $-\infty < u < \infty$ is known to be $\pi\exp(-|t|)$. Hence it is clear from (7) that the spectral distribution, instead of being concentrated (as for (1) above) at the single frequency $u = \omega$ of infinite density, is spread out continuously over the entire range $-\infty < u < \infty$. In fact, the density of probability in the resulting distribution is seen to be

$$\frac{d\varphi(u)}{du} = \frac{1}{\pi}\,\frac{1}{1 + (u - \omega)^2} \tag{9}$$

if either the value of a in (4) or the unit of length on the u-axis is so chosen that the constant (8) becomes 1.

It should be mentioned that the result (9) is precisely the *elementary* distribution of Cauchy, a stable distribution of infinite standard deviation, already encountered by P. Lévy in his work on normal stochastic processes[4].

Contraction of Time and Protoplasm

IN recent discussions concerning the clock paradox, biological time is mentioned but dismissed as of little consequence in the matter[1]. Contrary to this view and regardless of the solution finally found acceptable in the clock paradox, the entire problem really centres in biological time. Whether we accept or reject a completely mechanistic view of protoplasmic processes and therein compare them to an actual clock in the sense of their mechanical workings, or believe in other processes, in addition to the mechanistic view, the statement that biological time is the centre of the matter still holds. No one has ever shown that biological processes are identical in their functional attributes to the mechanical universe envisaged by the physicists. If biological time is not identical to the physicists' time then asymmetrical ageing is meaningless, so far as biological phenomena are concerned. One of the most outstanding physicists, upon analysing the meaning of life, gives an opposite view. Schrödinger[2] states: "from all that we have learnt about the structure of living matter we must be prepared to find it working in a manner that cannot be reduced to the ordinary laws of physics". I take it from this statement, and my own experience of more than twenty-five years of working with living materials, that the laws which control protoplasm are of a different order of integration from those of ordinary physics. This is not surprising in view of its functional complexity.

If we admit the postulates of the relativity theory apply to time–space factors, using a mechanical clock to reveal the asymmetry of the result, this is one thing; if we use a human or other living organism to reveal the result, the effects may predictably be an entirely different matter. The space–time dilatation is most profoundly related to biological processes in two obvious aspects: (1) all primary data upon which the concept is based are biologically sensorially derived; (2) if time–space factors are to show asymmetrical age differences in the stay-at-home versus the space traveller, then the biological processes of growth and ageing are involved.

Aspect (1), of course, looks directly into the whole problem of reality and causality. If as Russell[3] and others think, namely, that causality originates in perception, we can scarcely escape the implication of this in our reasoning about time dilatation and biological time. The two are closely linked. While the final status of biological time is probably in as confused a state[4] as is the clock paradox, we can, in a sense, deal with it in a more direct experimental manner.

The involvement of biological factors of ageing and growth processes in the relativistic contraction of time is very real. Biological matter has to exist not only in a physical inertial frame, of some sort, but also in some kind of time continuum. The problem here is whether or not biological material (protoplasm to be specific) is in any way affected as a function of velocity, or if it is affected in any way, or if the narrow bios zone which is an absolute necessity for survival of protoplasm also includes absolute velocity. (The discussion disregards acceleration, deceleration effects upon the intact animal which are in part understood.)

McCrea[5] mentions biological time but denies its importance through the route of making the difference between biological time and clock time arbitrarily small. He says that biological processes need not be standardized with a standard clock accompanying the system. This is the heart of the problem: is not our entire interpretation of time sense biologically conditioned? The question must be asked whether all the biological processes depend upon rate of travel of protoplasm The supposition is that growth processes will be retarded or actually reversed, yet everything we know about protoplasmic processes denies that this is possible. Living processes may be temporarily suspended under certain conditions, or slowed down, but the range of this is extremely narrow. Since all other factors, which maintain protoplasmic integrity, are of a narrow limited range, may not the same be true of the function of velocity? The interesting thing is that it does not seem to have occurred to anyone that experiments might well be performed in this connexion.

The implication in the work on asymmetric ageing is astounding since the physicists predict that increased velocity will slow up or reverse what are major biological functions, namely, the ageing and growth functions. It is as though they believe both of these are simply physical models of systems identical in final analysis to a clock. Without getting into the idea of entelechy, it suffices to state that while we may accept the physicist's view of biological materials we cannot deny that the order of organization of protoplasmic processes may be such that the ultimate upper integrative level of biological processes may function in a manner entirely different from the materials thus far tested on the electron–proton level.

Taking the other facet of the argument, assuming that the physicists are correct, and that growth and ageing processes are connected with velocity in the fashion they assume, it would be of extreme importance to determine this, since by utilization of the velocity factor we could modify living processes almost at will. Again an experimental approach is called for in order to secure the answer.

Propagation of Ultrasonic Waves in Liquids

We had observed[1] that the heat generated by ultrasonic waves in carbon disulphide and in other liquids, such as toluene and xylene, is not in conformity with their widely divergent absorption coefficients as measured by other (acoustic) methods. To clarify the point further, we have made a set of measurements with the type of apparatus described in ref. 1.

Working at about 32° C., it was observed with a particular apparatus that the total power generated by a vibrating quartz crystal, placed inside a container with kerosene oil or xylene, was 9 watts, as obtained from the steady temperature difference between the container and the circulating water outside. Energies were also measured in a trap-vessel, placed at a definite distance from the quartz; on both sides of it when the quartz was in the middle of the container, and on one side only when the quartz was near the end. It was observed that the energy propagated forward from the quartz placed near one end was 25 per cent higher than from the other position, where it was propagated equally on both sides. The energy propagated forward was thus found to be 5·6 watts only.

Measurements were taken with trap-vessels of different sizes, placed at different distances from the quartz, which was near the end of the container. The liquids outside and inside the trap vessels were varied. It will be seen from Table 1 that α/f^2, obtained from the variation of power with distance, drops from a comparatively large value near the quartz to a value of approximately the same order as that obtained by other methods.

Table 1

Liquids (*a*) outside (*b*) in trap	Distance from quartz (cm.)	Trap vessel size (cm.)	Power in traps (watts)	Incident power at 5 cm. (watts)	$\frac{a}{f^2}\times 10^{17}$ from displacement, liquid (*a*)	$\frac{a}{f^2}\times 10^{17}$ from incident energy, liquid (*b*)
(*a*) Kerosene (*b*) Kerosene	2	1	1·5	4·5		
	5	1	1·2		408	1,722
		5	2·0			666
		15	3·0		200	400
	10	1	1·0			
	15	1	0·85		180	
(*a*) Xylene (*b*) Xylene	2	1	1·4	4·5		
	5	1	1·02		583	1,444
		5	1·9			600
		15	2·3		255	270
	10	1	0·81			
	15	1	0·70		166	
(*a*) Kerosene (*b*) Carbon disulphide	5	1	2·0	4·5		3,330
		5	2·3			800
		15	2·4			325

A direct measure of the energy incident on a trap-vessel, passing through kerosene oil and out on the farther side, was obtained by placing the trap in a closely fitting glass container, 5 cm. from the quartz. The container was thus virtually partitioned into three thermostatic chambers, except for the communicating mica windows. It was cooled by water circulating outside. The power on the farther side of the trap-vessel was measured from the temperature difference between it and the circulating water. This is a measure of the vibrational and turbulent energy as well as of the heat passing out of the trap, having regard to the temperatures on the two sides. We obtained a value of 4·5 watts, incident on the trap-vessel transmitted through the windows, irrespective of the liquid inside.

The variation of the measured power with distance has already been noted. It shows that when the incident energy at 5 cm. from the quartz is 4·5 watts, the power output at the quartz is not less than 5·6 watts. It accounts for the energy that was found to be propagated from the quartz, and it appears that the mica windows do not reflect any detectable energy.

The power measured in the different vessels, placed at 5 cm. from the quartz, gives, having regard to the incident energy, a very high absorption coefficient for liquids known to have low absorbing power.

The coefficients, in the form α/f^2, so derived are shown in Table 1 (column 7).

The higher absorption of ultrasonic waves near the source as determined by energy variation with displacement is to be associated with the inharmonic character of the waves observed by Hubbard[2]. Moreover, the excessively high absorption in the 1-cm. trap-vessel, for low-absorption type liquids, was not caused by reflexion from the mica. It has also been confirmed that diffraction by the aperture does not account for this effect. The observations appear capable of explanation on the basis of a phase retardation of the components of the inharmonic wave-form, introduced by the first mica window. They become progressively out of step and are thus prevented from being fully transmitted by the second mica window. Even in unobstructed liquids, this mechanism appears to operate to a small extent and to account for the larger loss of energy at smaller distances. It supports the conclusion that the excessive absorption of ultrasonic waves noted in carbon disulphide and benzene (and possibly also the discrepancy from the Stokes absorption coefficient in other liquids) is due to a mechanism which produces more or less effectively a confusion in phase relationship during propagation, in the same way that the mica window does for low-absorption liquids such as xylene. It thus appears that wave trains in liquids can lose energy, as if by scattering, in a manner similar to that noted by Richardson[3] in the case of gases.

Protection of Fœtuses against Radiation Injury

The protection against a lethal dose of radiation, conferred on mice by grafts of hæmopoietic tissue, is being attributed to repopulation of homologous tissues of the host by cells from the graft[1]. This does not, however, exclude the possibility that such grafts might also be supplying a subcellular factor able to contribute to the recovery of the host.

To test the latter possibility, female mice of strain *A* were given, on the fourteenth day of pregnancy, a dose of X-rays amounting to 275 r. Immediately following this, and always under ether anæsthesia, they were splenectomized. One group was treated no further, while each animal of a second group was

Table 1. Weights (gm.) of Surviving Young at the Age of 37 Days

Young from 'ungrafted' mothers		Young from 'grafted' mothers	
Litter	Weight	Litter	Weight
A 1	5·0 4·0	*B* 1	13·6 15·5 14·0
A 2	6·0 5·5 4·9 5·2	*B* 2	11·6 11·1 12·3 8·0 6·4
A 3	5·9 4·0	*B* 3	11·6 13·9 12·9 15·0
A 4	4·2 12·4	*B* 4	11·8 14·0 14·0 12·5 12·5
Mean	5·7±2·3	Mean	12·4±2·2

given an intraperitoneal graft of six macerated livers from 18-day old fœtuses of the same strain.

Only six out of ten animals of the first ('ungrafted') group gave birth to litters. Dissection showed that resorption of fœtuses had occurred in the others. The six litters born included several still-born as well as twenty-six live young. Of the latter, twelve died within a week and another four died before weaning, having reached a weight of no more than 2–4 gm. each. The weights of the remaining ten at the age of 37 days are given in Table 1.

In contrast, all four females of the second ('grafted') group gave birth to litters, with a total of twenty-two live young and six still-born. Another five died before weaning; but the remaining seventeen developed to normal adult weight.

It would appear from these observations that the grafting of fœtal livers into the peritoneal cavity of pregnant mice subjected to irradiation improves the chances of the fœtuses to survive and enables those actually surviving to reach an adult weight twice as great as that of young from irradiated but ungrafted mothers. Experiments are being continued, based on the hypothesis that the effect of the graft is due to a humoral factor from it reaching the fœtuses *in utero*.

I am indebted to Prof. C. H. Waddington and Dr. D. Falconer for facilities provided at the Institute of Animal Genetics, Edinburgh, and to the Melville Trust for a Research Fellowship.

Hæmoglobin Types in Ox and Buffalo

Studies of ox and buffalo hæmoglobins by the technique of electrophoresis have been made by several workers. Geiger[1], using a technique of cataphoresis, resolved ox hæmoglobin into a component moving anodally and a component moving cathodally at a neutral reaction, and noticed that the two components had different oxygen-dissociation properties. Reiner, Moore, Lang and Green[2] and Munro and Munro[3], using the moving-boundary technique, resolved ox hæmoglobin into two components at an acid reaction. Using paper electrophoresis, Cabannes and Serain[4] found two varieties of hæmoglobin (which they called α and β) in 270 samples of North African oxen (α alone in 76·3 per cent, α plus β in 20·7 per cent, α alone in 4·0 per cent). Giri and Pillai[5] studied buffalo hæmoglobin on agar electrophoresis and resolved it into two components.

In the course of an investigation of human and animal hæmoglobin by the silicone-treated glass-plate electrophoresis technique[6] using veronal buffer *p*H 8·6 (ionic strength 0·06) and citrate buffer *p*H 6·5 (ionic strength 0·05), it became possible to study the hæmoglobin patterns in 27 oxen (*Bos banteng*) and 28 buffaloes (*Bubalus bubalis*) imported into Singapore from Bali.

In the ox, three types of hæmoglobin were detected (*A*, *B* and *C*, Fig. 1) and five patterns were obtained: *A* alone (nine cases, 33·3 per cent), *B* alone (eight cases, 29·6 per cent), *C* alone (one case, 3·7 per cent). *A* plus *B* (four cases, 14·8 per cent), and *A* plus *C* (five cases, 18·4 per cent). *A* was found in eighteen cases (66·6 per cent), migrated at a faster rate than normal adult hæmoglobin and is probably identical with Cabannes and Serain's β. *B* moved more slowly than *A*, very similar to normal adult hæmoglobin, and is probably identical with Cabannes and Serain's α. *C* moved faster than *A*. All three types moved anodally at *p*H 8·6, *A* and *B* being well separated, *A* and *C* less so. At *p*H 6·5 all three types moved cathodally, their relative migrations being reversed.

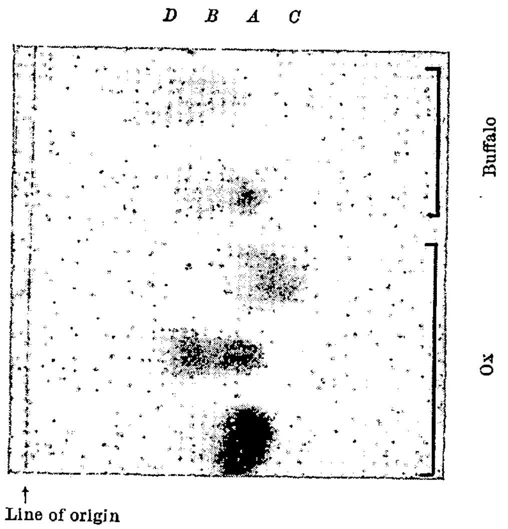

Fig. 1. Electrophoresis (Whatman 3*MM* filter paper) at *p*H 8·6 (ionic strength, 0·06), 360 V., 20 mA., 5–6 hr.

In the buffalo two components with mobilities identical with those of ox *A* and *B* were found in 27 cases (96·4 per cent), while in one case a small amount of a third component, moving more slowly than *B*, was noticed.

The one-minute alkali denaturation values[6] for the ox bloods varied between 70–90 per cent (average 75·2 per cent) and for buffalo bloods 64–90 per cent (average 79 per cent). Alkali denaturation patterns over 4 hr. were indistinguishable when ox *A*, *B*, *C*, *AB*, *AC* or buffalo bloods were used, indicating that several alkali-resistant hæmoglobins may occur in the same species.

Absorption spectra for ox *A*, *B* and *C* were determined between 2000–5000 A. They were found to be identical in all three cases.

Some Nutritional Requirements of *Colletotrichum coffeanum* Noack

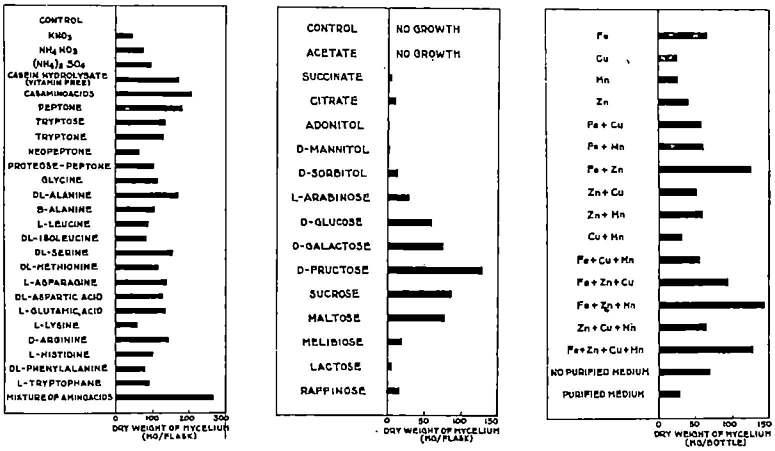
In the course of the studies on the physiology of plant pathogenic fungi causing diseases in tropical crops of Mexico, several strains of *Colletotrichum coffeanum* Noack were isolated from coffee plants (*Coffea arabica*) showing typical signs of leaf spotting and die-back. Very little is known about the nutritional requirements of this fungus, although observations concerning the taxonomy and pathogenicity have been reported from time to time[1]. However, some previous reports have made reference to various aspects of the physiological behaviour of the conidial stage of *Glomerella cingulata*[2], which is identified as *C. coffeanum*[3]. The purpose of this communication is to summarize our observations on one of the isolated strains.

A stock culture of *C. coffeanum* (*CF*–2) was maintained by serial transfers on potato–dextrose–agar slants. In all the experiments the fungus was grown in submerged culture using rotary shakers at 25° C. for 72 hr. The extent of growth was determined by weighing the previously washed and dried mycelium. Preliminary experiments revealed that the organism could grow in a wide range of *p*H values, from 2 to 9·5; 3·8 being the optimum. A basal medium was selected consisting of KH_2PO_4, 1·00 gm.; K_2HPO_4, 1·30 gm.; KCl, 0·50 gm.; $MgSO_4.7H_2O$, 0·50 gm.; $(NH_4)_2SO_4$, 2·0 gm.; distilled water, 1 litre and the *p*H adjusted to 3·8. All the chemicals were analytical grade. For the experiments on the effect of trace elements, a modified Pfeffer's solution was used containing, KH_2PO_4, 5 gm.; $MgSO_4.7H_2O$, 2·5 gm.; $(NH_4)_2SO_4$, 10 gm.; sucrose, 50 gm.; triple glass-distilled water, 1 litre. Most of the cultures were carried out in 125-ml. Erlenmeyer flasks containing 25 ml. of culture medium; however, for the experiments with trace elements it was found that 125-ml. polyethylene bottles could replace the 'Pyrex' glass flasks favourably, giving 2–5 times more efficiency in the growth response. As inoculum 2·5–3·0 millions of washed conidia obtained from submerged culture were added to each flask or bottle.

No significant stimulation was observed when the following vitamins at two concentrations (0·2 μgm. per ml. and 4·0 μgm. per ml.) were added separately to the basal medium: riboflavin, thiamine, pyridoxine, inositol, nicotinic acid, calcium pantothenate, *p*-aminobenzoic acid and folic acid. Biotin at the same concentrations gave slight stimulation. The mixtures of all vitamins did not significantly stimulate growth. These results indicated that *C. coffeanum* is self-sufficient so far as vitamins is concerned.

The utilization of different nitrogen sources was studied by adding the nitrogen compounds at a concentration of 0·5 gm. of nitrogen per litre of culture medium. The results (Fig. 1*a*) indicated that the fungus was able to assimilate nitrogen from both organic and inorganic sources. Among the inorganic sources, ammonium sulphate produced maximum growth; among the organic sources of nitrogen, DL-alanine was the best individual source, and a mixture of all the amino-acids tested supported maximum growth. Casein hydrolysates and some kind of peptones were satisfactory sources, whereas neopeptone (Difco) was a poor source of nitrogen.

Several carbon sources including carbohydrates, sugar alcohols and organic acids were added to the basal medium at a concentration corresponding to 8 gm. carbon per litre of medium. The results (Fig. 1*b*) indicated that D-fructose induced maximum growth; sucrose, maltose, D-galactose and D-glucose were fairly good carbon sources and, as a rule, sugar alcohols and organic acids did not support growth. When ammonium sulphate was replaced by DL-alanine as the nitrogen source, D-glucose appeared to be the best carbon source. The effect of trace elements was studied on a modified Pfeffer's solution purified by the Steinberg's technique[4] and dispensed in polyethylene bottles. The addition of iron and/or zinc ions at a final concentration of 0·2 μgm. per ml. favoured the growth of *C. coffeanum* strikingly (Fig. 1*c*). Combinations of iron, zinc and manganese ions gave the maximum growth response. Under the conditions of the experiments the addition of copper ions antagonized the favourable effect of iron ions.



(*a*) (*b*) (*c*)

Fig. 1. (*a*) Growth of *C. coffeanum* on a basal medium containing different nitrogen sources; (*b*) growth of *C. coffeanum* on a basal medium containing different carbon sources; (*c*) effect of trace elements on the growth of *C. coffeanum*

Detailed accounts of the experiments will be reported elsewhere.

Nutritional Requirements of the Common Housefly, *Musca domestica vicina* Macq

The housefly *Musca domestica vicina* Macq., which has been reared in our laboratory for four years with a modified NAIDM medium[1], was used in these experiments. Eggs were collected from oviposition dishes, washed and sterilized. The most satisfactory sterilizing solution and technique were as follows. Modified Vanderzant's solution[2] was prepared, with the omission of sodium glycocholate and less mercuric chloride (0·15 gm. instead of 0·25 gm.). Instead of a single treatment, the eggs were submerged in the solution twice, each for 10 min., with an interval of 1 hr. between the two treatments. After each treatment, the eggs were rinsed with bacteriologically sterile water. Plating on common bacteriological medium revealed that the percentage of contamination was less than 10 per cent and the percentage of eggs hatched was more than 50 per cent[3].

The sterilized eggs were transferred to cotton-stoppered vials with sterile media, one egg to each vial. Observations on the growth and development of the larvæ were made at frequent intervals and growth-rates recorded. Vials contaminated with micro-organisms were discarded.

The composition of the medium was based on the medium for *Hylemyia antiqua*[4] and *Calliphora erythrocephala*[5], since it is reasonable to assume that the nutritional requirements of these flies might be similar. The ingredients of the medium per ml. were as follows:

Agar	20·0 mgm.
Ribonucleic acid	1·0 ,,
Cholesterol	0·1 ,,
Dextrose	15·0 ,,
Mineral mixture (U.S.P. XIII, No. 2)	2·0 ,,
Casein	11·0 ,,
Vitamin mixture (per 100 ml.)	
Vitamin A	5,000 U.S.P. units
Rachitosterol D	1,000 ,, ,,
Thiamine	2·0 mgm.
Riboflavin	2·5 ,,
Ascorbic acid	30·0 ,,
Niacin amide	20·0 ,,
Pyridoxine hydrochloride	0·2 ,,
Calcium pantothenate	1·0 ,,

Solutions of casein and ribonucleic acid were prepared separately by dissolving in distilled water, the former with 2 *N* sodium hydroxide. The mineral mixture was dissolved in hot distilled water. These solutions were mixed and agar added. When agar was dissolved by heating, the whole mixture was autoclaved at 15 lb. for two minutes. Cholesterol was first dissolved in 95 per cent ethyl alcohol, and emulsified with 5 per cent gum arabic solution. This emulsion, together with dextrose solution and vitamin mixture, were then added. The final mixture was adjusted to *p*H 6·4 with 2 *N* sodium hydroxide. 2 ml. of this mixture was put in each food vial, a cotton stopper was used, and the vials were again sterilized at 15 lb. for 15 min.

Larvæ developed normally in the basic medium except that the larval period was somewhat prolonged and the pupal weight decreased (Table 1). This was probably due to the deficiency of glycine and cystine in casein. Further retardation of growth-rates resulted when ribonucleic acid or vitamins A, C and D were omitted. Non-sterile eggs on the same basic medium showed no advantages, suggesting that bacteria or other micro-organisms were not necessary symbionts for the housefly larvæ, at least when all other nutritional requirements were fulfilled.

Table 1. Growth-Rates and Pupal Weight of Houseflies reared on Basic Medium and Modified Medium

Medium	Larval period			Pupal period (days)	Pupal weight (mgm.)
	First instar (days)	Second instar (days)	Third instar (days)		
Basic medium	1	1	3–6*	3–5	12–15
Basic medium less ribonucleic acid	3	3	3–4	4	11–15
Basic medium less vitamins A, C and D	1–3	1–2	3–5	3–8	12–15
Basic medium non-sterile eggs	1–2	1	5–11	3–4	11–13
Casein hydrochloride hydrolysate	1–3	3–5	—	—	
Casein pancreatin hydrolysate	1–2	2–4	2–4	6	11–12
Ten amino-acids	3–6	3	7	4	11
Modified NAIDM	1	1	3–4	3	15–18

* One larva had an extremely long third instar of 10 days.

Preliminary experiments on the amino-acid requirements of the housefly larvæ had been studied by using different hydrolysates of casein. The casein hydrochloride hydrolysate failed to support growth due to the lack of tryptophan, while pancreatin hydrolysate of casein (tryptophan not destroyed during hydrolysis) will support normal growth. Preliminary studies by varying the contents of amino-acid mixture to substitute for casein had also revealed that the essential amino-acids were probably the same for other dipterous insects such as *Drosophila melanogaster*[6] and *Pseudosarcophaga affinis*[7]. They are arginine, lysine, leucine, *iso*leucine, tryptophan, histidine, phenylalanine, methionine, valine and threonine; but the rate of growth with only these ten acids was very much retarded. Further studies are now in progress.

Occurrence and Filterability of Protoplast-like Elements in Aged Bacterial Cultures

Cellular or subcellular units of certain bacteria that have been deprived of a rigid cell wall have been regarded in the recent literature as protoplasts. The conversion of rods into spherical protoplasts was observed mostly in media containing penicillin and magnesium ions plus sucrose as stabilizers[1], although Jeynes[2] has reported their natural occurrence.

The present communication describes the spontaneous occurrence of units in aged *Escherichia coli* cultures[3] which conform to the description of artificially induced bacterial protoplasts.

The *E. coli* strain used was isolated from human urine in 1952 and originally showed a certain degree of spontaneous polymorphism. Cultures were aged in horse-meat broth kept at 37° C. or at room temperature for several months in paraffin-sealed flasks. In electron-microscope preparations of samples from aged cultures the complete disintegration of some bacterial cells into naked plasmatic material containing electron-dense spots was readily observed. The disintegration was preceded by swelling of the cell and rupture of the rigid cell wall. Collodion membrane filtrates of the supernatant fluid (obtained after centrifugation at 2,000 r.p.m., 15 min.) of aged cultures contained units capable of regeneration when placed in fresh medium. The size of the smallest units so far found to regenerate has been estimated as approximately 350 mμ in diameter. Certain details of the regeneration were studied by light- and electron-microscopy. An initial fusion or coalescence followed by cell wall formation was noted. The individual protoplastic units were never observed to undergo division prior to fusion. The addition of washed *Sarcina lutea* cells to the filtrate appeared to stimulate the regeneration of the subcellular units. Microscopic observations and centrifugation experiments (Table 1) showed that this enhancement involved the adsorption of the protoplastic particles to the surface of the *Sarcina* cells.

Table 1. RATIO OF THE NUMBER OF CULTURES SHOWING GROWTH OF *E. coli* CELLS TO THE NUMBER OF TUBES INOCULATED WITH VARIOUSLY TREATED FILTRATES FROM AGED CULTURES

Samples	Experiment No. 1	2
Filtrate (*a*)	7/33	5/35
Sediment (*b*)	2/30	0/35
Sediment (*c*)	16/35	19/38

(*a*) Aged broth culture was filtered through a membrane with an average pore diameter of 600 mμ; the filtrate was adjusted to *p*H 5·8.

(*b*) The filtrate (*p*H 5·8) was centrifuged at 1,000 r.p.m. for 20 min., the sediment was resuspended in the original volume of fresh broth.

(*c*) Filtrate (*a*) (*p*H 5·8) was centrifuged at 2,000 r.p.m. for 20 min., following the addition of approximately 10^6 *Sarcina lutea* cells per ml.; the sediment was resuspended in the original volume of fresh broth.

0·2 ml. amounts of all the samples were distributed in broth tubes and incubated.

These results support the assumption that aged *E. coli* cultures can survive in the form of sub-units having no cell walls which, under adequate conditions, can regenerate into the vegetative form. Recent observations on ribonucleic and deoxyribonucleic acids as well as protein synthesis in protoplasts or in their subcellular fractions[4,5] give credence to the conception that they may retain the potential for reversion into the bacillary form. However, in relation to the number of protoplastic structures seen in the electron microscopic fields, the efficiency of regeneration obtainable so far must be considered as poor, even in samples filtered through membranes with large pore diameters.

The morphological resemblance of the *L* forms of *Proteus* to the protoplasts was recently pointed out by Pease[6]. The stimulatory effect of *Sarcina* or other bacterial cells on the growth of both protoplasts and pleuropneumonia organisms[7] suggests the existence of similar metabolic pathways.

Sexual Behaviour and the Vaginal Cycle in the Cat

DIFFICULTIES have been encountered in studying the neural and endocrine mechanisms which underly the control of sexual behaviour in the mammal for two main reasons. First, conspicuous and easily observable patterns of stereotyped behaviour, which are uninfluenced both by learning processes and the conditioning effects of the experimental situation itself, are rather few among laboratory mammals. Innate reflex patterns of behaviour similar to those successfully utilized by ethologists in lower animals, that are stable and difficult to disturb, occur quite infrequently in higher forms. The sexual behaviour of the female cat is a conspicuous exception to this. Though Marshall has emphasized the virtual impossibility of determining the state of the sexual cycle in many species by external signs alone, the present study shows this is not the case in the cat. The second source of difficulty arises from the observation that some of the components of the total pattern of sexual behaviour may not be dependent upon the secretory activity of the gonads; this is most evident in the male, but is also quite apparent in the female of several mammalian forms. The female chimpanzee may accept the male at any time in her cycle (Yerkes and Elder[1]); similar behaviour has been observed in the female rat (Boling *et al.*[2]); and acceptance by both diœstrous and ovariectomized rabbits is well established[3,4]. Sexual receptivity and the associated postural responses cannot be regarded as depending solely upon ovarian hormones in these species. This makes for difficulties in the interpretation of behavioural changes which appear to follow hormone administration. However, earlier studies by Bard[5] have indicated that the full pattern of sexual behaviour of the female cat may be strictly dependent on hormones.

Patterns of sexual behaviour shown by thirty reproductively active female cats were studied for two years. Specially trained males were used for conducting timed mating tests under standard environmental conditions. These tests are best carried out in an observation pen of suitable design where the male is allowed to establish territory rights. After an initial training period, a suitable male will mount and attempt copulation with any female that is presented. The normal sexual displays of mature, cycling females running with the male under free colony conditions were compared with the patterns of response obtained during these formally conducted mating tests, enabling an assessment to be made of the effect of the test situation upon behaviour throughout the cycle. The responses to artificial sexual stimulation and vaginal probing were also investigated.

$$n = (4-1)(4-1) = 9$$

From Fisher and Yates $\chi^2 = 27\cdot877$ for $P = 0\cdot001$.

It has been found that the behaviour patterns of individual animals are remarkably constant and that a well-defined behaviour cycle exists in this species. The behavioural characteristics specific to each of the four stages of the cycle, the anœstrous, the pro-œstrous, œstrous and metœstrous responses, will be enumerated in detail elsewhere. They were determined by combining the data on the responses of females to both artificial stimulation and the coital activity of the male during nine hundred mating tests. With the behavioural criteria established, an investigation was made of the relationship between behaviour and the cytology of the vaginal smear. 340 mating tests were conducted with 15 mature females and a corresponding number of vaginal smears collected. The description of the vaginal cycle given by Scott and Lloyd Jacob[6] was used, and the smears were examined without prior knowledge of the behavioural state of the animals from which they were obtained.

Correlating these data by means of a contingency table (Tables 1 and 2) reveals a highly significant association ($P < 0\cdot001$) between the behavioural patterns and the appearances of the vaginal smear at every stage of the cycle. The characteristic pattern of œstrous behaviour and the associated state of sexual receptivity, though commonly first appearing when the smear is pro-œstrous, continues throughout the period of full vaginal œstrous. The appearance of the metœstrous leucocytic infiltration in the smear closely coincides with the development of the metœstrous refusal pattern. Of the 142 observations on behaviour where the smear was anœstrous only once did mating occur, and in this particular animal the smear had cornified 24 hr. later. It can be concluded that mating behaviour with an anœstrous vaginal smear is a very unusual occurrence in this form, and further, that mating behaviour is almost invariably associated with either a pro-œstrous or œstrous smear. It was repeatedly observed that unless the specific œstrous posture is adopted, mating cannot take place no matter how energetic the copulatory efforts of the male. Only behaviourally œstrous animals can be mated; falsely positive mating tests due to 'rape' by the male do not occur in this species. Approximately 300 mating tests were conducted with 8 spayed females for periods of up to six months after operation during which time no vestige of œstrous behaviour was seen. Mating never occurred in this group even in those animals spayed at the height of œstrus and tested upon recovery from the anæsthetic 24 hr. later.

The highly conspicuous stereotyped mating response of the cat provides a sharp behavioural end-point for quantitative study and places it, in this respect, in a special position among laboratory mammals. The complete dependence of œstrous behaviour upon the presence of the ovaries has been confirmed beyond doubt. The relationship established between behavioural patterns and the state of the vaginal smear, together with the technique for conducting reliable mating tests, considerably facilitates the further study of sexual behaviour in this form.

Diseases of the Intervertebral Disk of the Cat

ALTHOUGH the domestic cat is known to suffer occasionally from spondylitic lesions of the vertebræ[1,2] it is not supposed to be susceptible to diseases of the intervertebral disks themselves[3]. If any species of mammal can be shown to be free, or relatively free, from diseases of the disk it should be profitable to compare the functional anatomy of its vertebral column with that of mammals known to be susceptible. This might uncover anatomical factors influencing diseases of the disk in general, or protrusion of the disk (herniation of the nucleus pulposus) in particular. This line of reasoning has in fact already been attempted on the basis that the dog and man are much more susceptible than the cat[3,4].

In 100 adult cats we have found dorsal (posterior) protrusions in 26, a total of 91 disks being affected. Two types could be distinguished: in one the protruded mass perforated the annulus fibrosus, and in the other it caused a bulge without passing right through the annulus. The distribution of protrusions along the vertebral column is summarized in the histogram in Fig. 1.

In 50 of the cats, we investigated the incidence of macroscopic degenerations other than dorsal protrusions. Ventral (anterior) protrusions were found in eight cats, and a lateral protrusion was found in one. Calcification was seen in three cats and 'brown degeneration' in 15. General disorganization of the disk, sometimes attaining almost complete destruction, was much the commonest form of degeneration, for it was found in 27 cats and involved 178 disks; the distribution along the vertebral column of this general degeneration is summarized by the graph in Fig. 1.

These findings show that the cat is by no means indifferent to diseases of the intervertebral disk. If our survey of the incidence of dorsal protrusions in the cat is compared with the two main corresponding surveys in the dog[3,5] it appears that the cat is in fact nearly as susceptible as the dog. Unfortunately this nullifies the attempt, referred to above, to detect anatomical factors behind protrusion of the disk. However, it is a consolation that it helps previous efforts[3], hitherto based only on the dog, to dispose of the idea[6] that man's susceptibility to disk protrusion is simply due to his upright posture.

Analysis of the distribution along the vertebral column of dorsal protrusions and of other degenerations has been employed as another way of detecting anatomical factors. Taken as a whole, the first nine thoracic disks (*T*1–2 to *T*9–10 inclusive) are relatively immune to dorsal protrusion in the cat (and in the dog), even though general degeneration is particularly common. The conventional explanation for this in the dog is that the conjugal ligaments (which cross over each of these nine disks, in order to join the heads of nine pairs of ribs) support the disks dorsally and so prevent protrusion[3,5]. However, this is unlikely to be the whole answer. In the cat the first conjugal ligament is usually of negligible thickness, and therefore could scarcely be the sole reason for the rarity of protrusions from the disk which it covers (*T*1–2). A similar objection applies for the dog[7].

In the dog the highest incidence of both dorsal protrusions and general degeneration occurs in the last thoracic disks, between *T*10–11 and *T*13–*L*1 [3]. This region includes the point of maximum normal kyphosis and the supposed site of maximum mobility of the trunk; consequently curvature and mobility seem to have been suspected as possible factors controlling disk disease in this quadruped[3]. The point of maximum normal kyphosis and the supposed site of maximum mobility[8] in the trunk are much the same in the cat as in the dog. Yet in the cat the incidence of dorsal protrusion and general degeneration is low in this region. This seems to show that curvature and mobility may not be so important after all. However, there are reasons why this argument may be altogether too facile. First, although kyphosis may look similar in the dog and cat, the anatomical reasons for it may be different. At least two independent features can produce it, wedge-shaped disks and wedge-shaped vertebræ; these have not yet been assessed in mammals other than man. Secondly, mobility seems to have been inadequately studied[9]. When these and other fundamental data are available about the functional anatomy of the vertebral column of various mammals, analysis of the distribution of lesions of their disks may be a useful approach to the underlying causes of diseases of the intervertebral disk and especially of dorsal protrusion.

Sudanophil Inclusions in Ameloblasts, Odontoblasts and Cells of the Oral Epithelium

During studies of the lipid inclusions in cells of teeth and of the oral cavity of the rat, Baker's sudan black *B* method[1] was employed. The oral soft tissues were fixed in formalin–calcium solution, postchromed, embedded in gelatin, and cut on the freezing microtome. The enamel organ and pulp were dissected from the upper incisor tooth and similarly treated. Equally good results could be obtained from teeth if the entire tissue was decalcified with ethylenediamine tetraacetic acid (0·5 *M*) at *p*H 7·4, or with 10 per cent acetic acid, after fixation and before post-chroming. Beams and King[2] had investigated the Golgi bodies of dental tissues using Nassanow's method[3], and so this procedure was also used. Pyridine extraction of the tissues using Baker's method[4] was made in some cases. The results of the two methods agreed well on oral mucosa and that of the tongue.

Ameloblasts. Beams and King[2], using the Nassanow technique, described the changes in orientation of the osmic acid staining material in ameloblasts as these cells approached maturity and functional activity. These results were confirmed by me using Nassanow's technique. But with the sudan black stain, deep blue or black granules were seen in the undifferentiated ameloblasts, scattered throughout the cytoplasm in an almost haphazard way. In the tall functional ameloblasts, the granules tended to be more on the enamel side of the nuclei (Fig. 1), but were still scattered throughout the cell. The cytoplasm on the enamel side of the nucleus took up more sudan black than that elsewhere. These granules were completely removed by pyridine if extraction was made before postchroming, but were little affected if extracted after postchroming. In contrast, the lipid granules of the oral mucosa were completely removed by pyridine whether extraction preceded or followed postchroming. Pyridine extraction likewise removed all osmiophil granules from ameloblasts and oral epithelium cells.

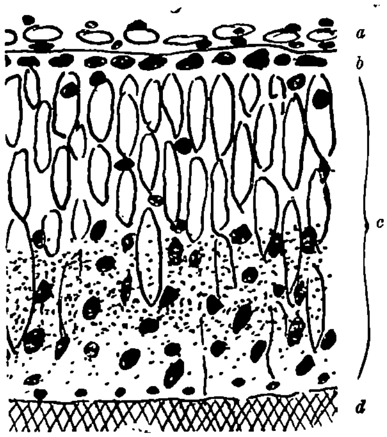

Fig. 1. Tall ameloblasts of the rat's upper incisor tooth stained by Baker's sudan black method. The sudanophil granules are black and the stippled area also stained with sudan black. × approx. 1,200.
a, Stratum intermedium; *b*, row of basal granules; *c*, tall ameloblasts; *d*, enamel

Basal granules. These are found only in the tall ameloblasts, at the stratum intermedium end of the cell. Beams and King[2] found them strongly osmiophilic, which I have confirmed. They also stained intensely with sudan black, with or without preliminary postchroming, and their staining was not affected by pyridine extraction. They thus seem to be chemically different from the lipid granules in the ameloblasts; but their nature is not known.

Odontoblasts. Unlike the osmiophil granules described by Beams and King[2], the sudanophil granules were distributed at random throughout the cytoplasm. These granules were removed by pyridine if extraction was done before postchroming, but were not soluble after postchroming.

Baker[5] has recently given a summary of the Golgi controversy, from which it would appear that inclusions in any cell, staining with osmic acid or silver, in a manner similar to that originally described by Golgi for nerve cells, have often unreservedly been called Golgi bodies or apparatus. It seems clear from the above results that sudan black stains more structures in the tooth cells than does osmic acid, and also that the properties of these inclusions differ in some respects from those of the oral epithelium. It is therefore unwise to append the name Golgi to them at all; in fact, Baker[5] has suggested that the name 'Golgi apparatus' should be abandoned.

Note added in proof. Since this communication was written, Symons[6] has reported findings with sudan black similar to those described above.

Effects of *Simulium* Control on Insectivorous Fishes

EXTENSIVE evidence from North America shows that DDT, at concentrations lethal to *Simulium* larvæ, need have no direct, harmful effect on fishes[1]. However, it may severely affect other aquatic insects[2-4], notably Ephemeroptera and Trichoptera[2,4,5], which are known to be important as food for many insectivorous fishes. It follows that the feeding habits of some fishes are likely to be modified considerably by insecticidal treatment, yet apparently this aspect of control has only once[5] received attention in the past. In view of the *Simulium* control measures envisaged in Africa, it is considered desirable to record some effects of DDT on the feeding habits of fishes in Uganda.

During March 2–May 4, 1956, the Victoria Nile at the Owen Falls, Jinja, was treated with DDT in order to eliminate larvæ of *Simulium damnosum* (Theobald) between Jinja and Mbulamuti. This dosing has been described elsewhere[6]. On several occasions before and during the treatment the sluice gates in the Owen Falls Dam were closed temporarily, resulting in marginal exposure of the river bed. Advantage was taken of this opportunity to sample the fauna and thus to assess the effects of the treatment.

In the Victoria Nile the DDT affected the invertebrate fauna differentially: some groups seemed unaffected, whereas almost all species of Ephemeroptera and Trichoptera were eliminated. Certain species of insectivorous fishes were collected before and after March 2 from points 100–500 m. below the dosing point, and their stomachs examined for food. These fishes adapted themselves to the changed conditions with varying success.

Clariallabes petricola Greenwood (Clariidae) proved the most adaptable. Before March 2, 83 per cent of fishes contained lithophilic Ephemeroptera larvæ. When deprived of these, *C. petricola* exploited a wide range of plant and animal food: on various post-treatment occasions it fed extensively on chironomid and tipulid larvæ, on Copepoda and on fresh plant material. After recolonization of Ephemeroptera and Trichoptera had begun in mid-June, it returned to its original diet.

Gnathonemus longibarbis Hilgendorf and *Mormyrus kannume* Forskal (Mormyridae) had previously obtained their food from two sources: stones of the river bed and marginal grass swamp. When the lithophilic insect fauna became reduced, these fishes fed to a greater extent on the swamp insects, the position of which had protected them from the effects of DDT. *G. longibarbis* proved better able to adapt itself in this way than *M. kannume*.

The most specialized feeding habits were encountered in *Mastacembelus victoriae* Boulenger (Mastacembelidae), of which 92 per cent had been feeding on lithophilic Ephemeroptera larvæ before March 2. For at least five weeks after the dosing, specimens were very scarce, and only 50 per cent (as against 94 per cent previously) of the fishes collected had food in the gut. Then the commonest items of food were small fishes and Hirudinea, which had seldom featured in earlier gut samples. It appears that *M. victoriae* either moved away from the area, or else was obliged to suffer starvation. Like *C. petricola* it gradually resumed its original feeding habits when repopulation of the lithophilic insects took place.

These observations provide an indication of responses to DDT to be expected in certain insectivorous fishes. In the present instance, effects of treatment were greatly mitigated by the rapid recolonization of the main food items, which occurred from unaffected breeding populations upstream from the dosing point. This mode of relief, however, must be regarded as exceptional, since most *Simulium* control in Africa is planned for highland streams where repopulation is unlikely to take place rapidly enough to be effective. Since many fishes in such habitats rely mainly on lithophilic insects for food, *Simulium* control there may cause the extinction of many little-known or undiscovered animals. It is felt, therefore, that a strong case exists for making collections and hydrobiological surveys before extensive control measures are put into force.

The work described here is to be published in full elsewhere.

Photosensitization of Bacteria by Furocoumarins and Related Compounds

IT has been known for many years that exposure to the simultaneous presence of various dyes and visible light results in the death of bacterial cells. This effect has been found to vary with different organisms, but in general, Gram-positive bacteria appear to be more sensitive[1,2]. Recently, Stainer and Cohen-Bazire[3], and Dworkin and Stanier[4] have reported that a mutant of *Rhodopseudomonas spheroides* devoid of carotenoid is killed on exposure to visible light, due to the photosensitizing action of endogenous chlorophyll. Photosensitization of human skin by topical application of another group of compounds, the furocoumarins, has been shown by Musajo *et al.*[5] to result in erythema, œdema, and vesicle formation on irradiation with long wave-length ultra-violet light. Fitzpatrick *et al.*[6] have demonstrated the same responses, as well as increased pigmentation, upon ingestion of the furocoumarin 8-methoxypsoralen. Photosensitization of bacteria by psoralen and related compounds is described in this communication.

The compounds were tested for activity by a paper-disk diffusion method on agar plates. The nutrient agar medium contained 0·3 per cent beef extract, 0·5 per cent peptone, 0·1 per cent yeast extract, 0·1 per cent dextrose, 0·05 per cent dipotassium hydrogen phosphate and 1·5 per cent agar. Whatman No. 2 filter paper disks, 6·1 mm. in diameter, were impregnated with 100 μgm. of the test compound. Six disks impregnated with different compounds were arranged uniformly on a freshly solidified 12-ml. agar layer in a 10-cm. Petri dish, with a dish impregnated with psoralen in the centre. A 6-ml. agar layer seeded with 0·02 ml. of an overnight broth culture of the test bacteria was carefully poured over the disks. After solidification of the second layer, the plates were incubated in the dark at 37° for 3 hr. before irradiation, to allow for diffusion of the test compound through the agar. Duplicate plates were left in the incubator to determine antibacterial activity. The test preparations, with the Petri dish covers removed, were irradiated 15 cm. from the pressed glass Wood's filter of a Model 70 Glo-Craft lamp (Switzer Bros., Inc., Cleveland, Ohio). The principal output of this lamp is the 3654-A. band of the mercury high pressure arc spectrum. After irradiation, the plates were reincubated in the dark at 37° overnight.

Single strains of *Bacillus subtilis*, *Escherichia coli*, *Proteus vulgaris*, *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Streptococcus faecalis* were tested against each compound at irradiation times of 20 and 40 min. Activity of the compounds was determined by measuring the diameter of bacteria-free zones surrounding the impregnated disks; the minimum measurable zone of inhibition was 6·1 mm., the diameter of the disk. The irradiation procedure itself had no effect on bacterial growth. Table 1 presents the results of 20-min. irradiation of those compounds found to be active. Irradiation for 40 min. resulted in only slightly larger zones. As noted in Table 1, partial, rather than complete, inhibition was observed with four compounds against some organ-

Table 1. INHIBITION PRODUCED BY ULTRA-VIOLET IRRADIATION IN THE PRESENCE OF FUROCOUMARINS AND RELATED COMPOUNDS

Compound	Inhibition zone (mm.)					
	Gram-positive			Gram-negative		
	B. subtilis	*S. aureus*	*S. faecalis*	*E. coli*	*P. vulgaris*	*P. aeruginosa*
Psoralen	19	21	20	17	25	9
5'Methyl-psoralen	19	21	19	10	17	0
5',8-Dimethyl-psoralen	20	21	22	0	14	0
4,5',8-Tri-methyl-psoralen	21	23	18	0	10	0
5-Methoxy-psoralen	16	18	18	0	10	0
8-Methoxy-psoralen	19	20	20	12*	15	0

Visnagin	16	17	12	0	0	0
Khellin	14	12*	11*	0	0	0

* Partial inhibition.

isms. In these cases the zone boundaries were not distinct. On non-irradiated plates there were a few instances where anti-bacterial activity of the compounds shown in Table 1 was observed. The zone diameters of inhibition on such plates were as follows: psoralen with *B. subtilis*, 7 mm.; 8-methoxypsoralen with *B. subtilis*, 9 mm.; psoralen quinone with *B. subtilis*, 12 mm.; with *S. aureus*, 11 mm., with *S. faecalis* and *E. coli*, 7 mm.; thiocoumarin with *S. aureus*, 8 mm. Photosensitization was demonstrated by the appearance of much larger zones of inhibition on the irradiated plates, and this effect compared with that of 16 hr. or more dark contact with the diffusing compound, leaves no doubt about the role of light in the phenomenon. Indeed, most of the furocoumarins and related compounds showed activity only on the irradiated plates. As with dyes and visible light, Gram-positive organisms are more susceptible to photosensitization by these compounds.

The following furocoumarin derivatives were found to be inactive: 8-hydroxypsoralen, 5-geranyloxypsoralen, 2-thio-8-methoxypsoralen, 5-amino-8-methoxypsoralen, 5-nitro-8-methoxypsoralen, and 3,4-dihydro-8-methoxypsoralen. Of the furochromones, khellin and visnagin were active, but chellolglycoside and visamminol were not. The pyranocoumarins samidin, dihydrosamidin, and visnadin were also inactive. 3-Hydroxyflavone and six naturally occurring flavanoids gave no photosensitization; conversely, anti-bacterial activity on the unirradiated controls of three of the compounds was lost on irradiation. Other related compounds showing no activity were *o*-hydroxycinnamic acid, caffeic acid, cinnamic acid, 2-acetobenzofuran, phloridzin, 4-(*p*-methoxyphenyl)-3-buten-2-one, and twenty-two variously substituted coumarins. Coumarin was inactive at the usual 100 μgm. per disk; but very slight photosensitization did appear at 200 μgm. per disk. Eosin and methylene blue were inactive when tested in this system.

Eight of the thirteen active compounds reported here are found in various plant species. All the active compounds are weakly fluorescent except for psoralen quinone and thiocoumarin. However, since many of the inactive compounds are also fluorescent, this characteristic cannot *per se* confer photosensitization activity. Estimation of the relative activity of the various compounds would be hazardous, since the comparative rates of diffusion are unknown. However, their similar molecular weights and solubilities should result in similar diffusion rates.

The simultaneous presence of bacteria and compound is required for the effect since pre-irradiation of disks impregnated with 8-methoxypsoralen either alone or on the base agar layer resulted in no activity against *S. aureus* or *P. vulgaris*, no matter whether the seed layer was added immediately following irradiation or after three hours incubation. Irradiation of mixtures of 8-methoxypsoralen and bacteria in saline, followed by conventional plating techniques for surviving organisms, clearly shows that this photosensitization is bactericidal. Investigations are in progress on the kinetics of the lethal action and the effect of environmental factors.

We are indebted for some of the compounds used in this study to Dr. B. E. Christensen, Oregon State College, Corvallis, Ore.; Paul B. Elder Co., Bryan, Ohio; Givaudin-Delawanna Inc., New York; S. B. Cell Wall Composition in Bacterial and *L* Forms of *Proteus vulgaris*

α-ε-Diaminopimelic acid is known as an important constituent of the 'basic structure' of the bacterial cell wall[1-3]. As *L* forms seem to have a much less rigid cell wall than bacteria, the assumption that the *L* forms lack a normal wall became a main issue[4,5]. It was suggested that penicillin blocks some of the steps necessary for the condensation of the definitive wall. Recently, Weidel[6] has concluded from his experiments on phage enzyme that the main site of action of penicillin is the 'basic structure', consisting of α-ε-diaminopimelic acid, glutamic acid, alanine, glucosamine and muramic acid. Accordingly, this fraction should be missing in the *L* forms.

Comparative studies of the amino-acid composition of the bacterial form and the unstable and stable *L* form of *Proteus vulgaris* have shown[7] that the unstable form still contains α-ε-diaminopimelic acid, whereas it is absent in the stable form. In recent studies, Weibull found small amounts of α-ε-diaminopimelic acid also in a stable *L* form strain[8].

Attempts were made to isolate the 'basic structure' from the *L* form of *Proteus vulgaris*. The material and culture methods used were the same as those described earlier[9,10]. Most of the experiments were carried out on a stable (*A* strain) form cultivated on penicillin-free media for more than 200 passages without any sign of reversion to the bacterial form, and on an unstable (*B* strain) form, which had been transferred about 100 times on penicillin-containing media, without losing the ability to form normal rods when penicillin was omitted.

To isolate the wall material a recently described[11] simple method was applied. Bacterial or *L* forms were cultivated in a liquid medium and harvested by centrifuging for 20 min. at 15,000*g*. After washing the organisms twice in a 2 per cent sodium chloride solution they were suspended in 1 *N* sodium hydroxide and heated at 60° C. for 60 min. After diluting the sodium hydroxide to 0·5 *N* the undissolved material was centrifuged for 30 min. at 25,000*g* and the resulting gelatinous sediment was suspended again in 1 *N* sodium hydroxide. After heating at 60° C. for another hour the sediment was kept at 37° C. for 12 hr., then centrifuged again, washed with

Table 1. AMINO-ACID CONTENT OF HYDROLYSATES FROM THE BACTERIAL AND UNSTABLE *L* FORM OF *Proteus vulgaris*, EXPRESSED IN MOL. (α-ε-DIAMINOPIMELIC A ID (DAP) REFERRED TO AS 1) OR IN PER CENT OF ALL THE COMPOUNDS MENTIONED IN THE TABLE

	Mol.			Total (per cent)		
	Bacterial form		*L* form	Bacterial form		*L* form
	Whole cells	Wall fraction	Wall fraction	Whole cells	Wall fraction	Wall fraction
DAP	1·0	1·0	1·0	0·63	8·0	18·2
Glutamic acid	26·0	1·8	1·1	16·3	14·5	20·0
Alanine	23·0	3·3	2·0	14·5	25·5	36·0
Glucosamine	2·2	0·3	0·35	1·35	2·4	6·9
Muramic acid	?	0·2	0·2	?	1·6	3·4
Glycine	9·3	1·0	0·16	5·8	8·0	2·9
Serine	11·7	0·8	0·12	7·3	6·4	2·2
Lysine	20·0	1·2	0·16	12·6	9·7	2·9
Valine	17·2	0·70	0·05	10·2	5·6	0·9
Leucine	27·0	1·3	0·12	17·0	10·5	2·2
Aspartic acid	21·7	0·8	0·20	13·6	6·4	3·6

1 *N* sodium hydroxide and then three times with distilled water. Then the sediment was suspended in 6 *N* hydrochloric acid and boiled under reflux for 36 hr. The hydrolysate was tested for its amino-acid content by two-dimensional paper chromatography using two solvent systems—*iso*propanol (70), acetic acid (10), water (20); and picolin (78), ammonia (2), water (20) or picolin-solvent and water-saturated phenol. For the qualitative determination of α-ε-diaminopimelic acid the method of Ruhland *et al.*[12] was used.

The quantitative determination of the amino-acids was carried out according to Barrollier[13]. As shown in Table 1, α-ε-diaminopimelic acid predominates strongly in the wall fraction. Threonine, tyrosine, methionine, histidine, phenylalanine, proline and cystine (cysteine) are scarcely detectable in the wall fraction and are therefore not mentioned in Table 1. The composition of this cell wall fraction is probably very similar to the fraction, which Weidel[6] was able to split off *E. coli* using the phage enzyme. According to the density of the spots in his Fig. 2, there are also considerable amounts of lysine, glycine and valine (leucine is not shown) besides the main components (α-ε-diaminopimelic acid, glutamic acid and alanine).

When treating the stable *L* form (*A* strain) in the same way, the alkaline solution becomes entirely clear, and nothing can be centrifuged down. Sometimes very little of a white sediment could be obtained, but the hydrolysate showed a very complex composition without a trace of α-ε-diaminopimelic acid.

On the other hand, when unstable *L* forms (*B* strains) were used there was a slimy sediment as in the bacterial form. The hydrolysate showed a very pronounced pattern on the chromatogram, much more like the 'basic structure' of the cell wall of Gram-positive bacteria than that of the bacterial form. More than 80 per cent of the ninhydrin-positive substances are main components of the 'basic structure'.

Table 2. α-ε-DIAMINOPIMELIC ACID (DAP) CONTENT OF THE HYDROLYSATE FROM WHOLE CELLS OF THE BACTERIAL AND *L* FORM OF *Proteus vulgaris*; PERCENTAGE CALCULATED ON A MOLAR BASIS

	Bacterial form			*L* form		
	Total nitrogen (μmol.)	DAP (μmol.)	DAP (per (cent)	Total nitrogen (μmol.)	DAP (μmol.)	DAP (per (cent)
log, phase	357	0·31	0·085	470	0·82	0·17
Stat. phase	350	0·39	0·113	380	1·47	0·38

Further investigations will be made to find out if the high percentage of glycine, serine, valine and other 'impurities' in the wall fraction from the bacterial form is due to incomplete extraction or if it indicates that in the normal wall a protein component is present which is missing in the unstable *L* forms.

Although the results in Table 1 show that the 'basic structure' of the wall is also present in the unstable *L* forms, it might be possible that the total amount is much less than in the normal rods. To answer this question, rods and *L* forms were harvested from growing and resting cultures (bacterial form 4 and 25 hr., respectively; *L* form 18 hr. and 4 days), washed with 2 per cent sodium chloride and hydrolysed. Aliquots from the filtered hydrolysate were subjected to total nitrogen determination and to 1-dimensional chromatography in *iso*propanol–acetic acid, which allowed the measurement of α-ε-diaminopimelic acid. The results in Table 2 illustrate that in growing cultures as well as in resting ones the α-ε-diaminopimelic acid content of the *L* forms is higher than that of the rods.

Thus, penicillin does not prevent the synthesis of the 'basic structure' of the cell wall, nor does it prevent its condensation to an alkaline-insoluble macromolecular structure. The reason for the fragility of the unstable *L* forms must be sought in another wall component. The fact that our stable *L* forms lack the basic structure completely is in good agreement with our earlier findings[7,9] and indicates again that we are dealing with different types of *L* forms.

We are indebted to Dr. R. E. Strange, Dr. K. McQuillen and Dr. C. Weibull for kindly supplying the muramic acid and the α-ε-diaminopimelic acid. This work has been sponsored by the Deutsche Forschungsgemeinschaft.

Antigenicity of a Bacterial Deoxyribonucleic Acid

SINCE earlier evidence (refs. 1–3 and Medawar, P. B., personal communication) suggesting a serological reactivity for deoxyribonucleic acid (or the deoxyribonucleic acid moiety of a nucleoprotein) has been indirect or controversial, the problem has been

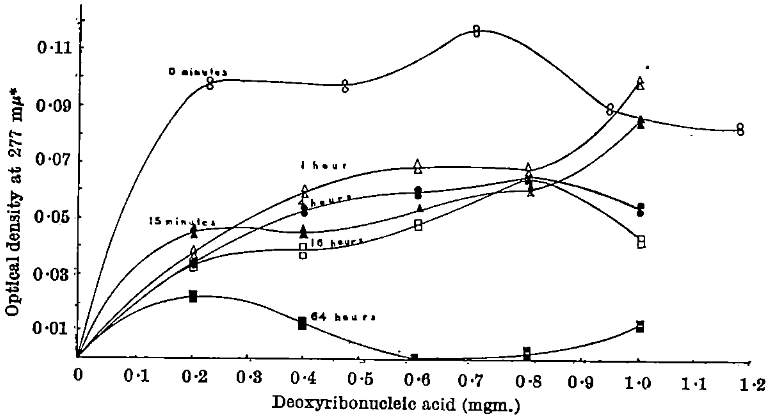

Fig. 1. Effect of deoxyribonuclease on quantitative precipitation. Antiserum, pooled rabbit anti-*Brucella abortus* - 19*M* deoxyribonucleic acid; antigen, homologous deoxyribonucleic acid after treatment with Worthington deoxyribonuclease for various periods of time†.

* 277 mμ is the wave-length of maximum absorption for the dissolved precipitate in 0·25 *M* acetic acid.

† Action of deoxyribonuclease was terminated by addition of ethylenediamine tetraacetic acid to the reaction mixture.

re-investigated with the aid of a preparation rich in deoxyribonucleic acid with transforming activity[4,5], isolated from *B. abortus* cells by extraction with 0·5 per cent phenol in citrate–saline. The extracted material was 'deproteinized' by chloroform and amyl alcohol treatments[6], but the final material still contained, in addition to typical deoxyribonucleic acid[5], approximately 20 per cent protein that could not be dissociated by conventional procedures. Such preparations of deoxyribonucleic acid were used for immunizing rabbits, and the resulting antisera were tested first for precipitating antibodies against homologous deoxyribonucleic acid by the gel diffusion method[7].

Five bands of precipitation, indicating more than one antigen–antibody system, were detected. One of these bands yielded a strong Feulgen-positive reaction, suggesting the presence of deoxyribonucleic acid in the precipitate. The described reactions remained identical when the test antigen was treated either with detergent, 6 *M* sodium chloride, trypsin, trypsin plus chymotrypsin, or when the antisera were first absorbed with whole cells. However, even though deoxyribonuclease alone did not react with the antiserum, treatment of deoxyribonucleic acid with deoxyribonuclease (Worthington 1 × crystallized) resulted in a noticeable decrease in intensity of one of the bands and a simultaneous increase in another.

A more decisive indication of the involvement of deoxyribonucleic acid in these precipitin reactions was obtained by quantitative procedures[8] in which various amounts of antigen were mixed in test tubes with a constant amount of antiserum. The resulting precipitates were washed free of contaminating serum proteins and excess antigen, were dissolved in 0·25 *M* acetic acid, and were analysed spectrophotometrically at 277 mμ. Normal serum controls were also included in all tests. The number of maxima in the resulting quantitative precipitin curve (Fig. 1) again indicated the complexity of the material under study. However, what appears to be of greater significance are the changes occurring following treatment of the antigen with deoxyribonuclease for different periods of time. A significant decrease in the amount of precipitate occurred throughout most of the tested range following treatment with deoxyribonuclease for as little as 15 min. An analysis of the precipitate in the region of lowest antigen concentration, in terms of the ratio of absorptions at 260 and 277 mμ, revealed the presence of deoxyribonucleic acid which decreased with increasing time of treatment with deoxyribonuclease. This deoxyribonucleic acid could have been precipitated either because it contributed to the immunological specificity of the antigen, because it was firmly bound to the antigen, or because it coprecipitated with an unrelated antigen–antibody precipitate. The virtual abolition of antigenicity following prolonged enzymatic treatment, the absence of coprecipitation with known unrelated antigen–antibody precipitates, and the absence of any detectable proteolytic activity in the deoxyribonuclease used, favour the conclusion that deoxyribonucleic acid itself contributed to the specificity and is not merely an inert part of the antigens. This is further supported by the apparent interdependence of the specific precipitates formed as a function of the time of treatment with deoxyribonuclease (note vacillations in the quantity of precipitin formed and apparent shift of maxima to regions of higher antigen concentrations in Fig. 1). This may be due to the formation, during partial depolymerization of deoxyribonucleic acid, of antigenically active molecules with quantitatively different antigenic characteristics.

Additional support for the involvement of deoxyribonucleic acid in these antigen–antibody reactions has come from preliminary tests of cross-reactions between the described antisera and deoxyribonucleic acid from different sources. Deoxyribonucleic acid from both smooth and non-smooth *Brucella* cells gave the same patterns of precipitation in gel diffusion. In contrast, equal amounts of deoxyribonucleic acid isolated either from calf thymus (duponol-extracted) or salmon sperm (phenol-extracted) yielded much weaker reactions. However, exposure of the heterologous antigens to deoxyribonuclease resulted in a striking increase in their cross-reactivity, as evidenced by an increase in precipitation and the appearance of additional zones. Such effects would be difficult to explain on the basis of similarities in the protein moiety. Finally, preliminary evidence suggests a capability of these antisera to antagonize the selective effects of deoxyribonucleic acid breakdown products upon changes in population from non-smooth to smooth in growing *Brucella* cultures[4].

The present information fails to reveal whether the formation of specific antibodies requires protein bound to deoxyribonucleic acid or involves only the acid molecule. However, from a genetic, biological, and analytical point of view it would appear that the answer to this question may be less critical than the indication that deoxyribonucleic acid can contribute to the specificity of an antigen.

We wish to express our appreciation to Prof. M. Heidelberger for his interest, suggestions and stimulating discussions. This work was supported in part by grants from the U.S. Public Health Service

Relaxation of Snails before Fixation

Numerous narcotizing agents have been used for relaxing snails, and among the more important of these employed recently are menthol and nembutal[1,2,4]. Menthol has been reported as giving variable results[4]; some snails become well extended, but others contract when this agent is used. This variation in results is observed especially when larger freshwater snails (shell height 15–25 mm.) such as *Lymnaea palustris* and *Physa gyrina* are placed in water to which menthol crystals have been added. On the other hand, smaller lymnæids such as *L. humilis* (maximum shell height, 12 mm.) relax well with menthol[3]. Nembutal gives good results with *Pomatiopsis lapidaria* and *P. cincinnatiensis*[4], but, like menthol, is unsatisfactory for the much larger *L. palustris*. This snail will contract slowly over a period of 4–5 min. when placed in 10 per cent formaldehyde even after being in rather high concentrations of nembutal (5 ml. stock veterinary nembutal in 150 ml. water at 4° C. for more than 40 hr.). Using this concentration of nembutal at room temperature results in contraction of *L. palustris* before it is properly narcotized, so that it is unsuitable for fixation. The same result occurs with snails in higher concentrations of nembutal (10 ml. in 150 ml. water) at 4° C.

However, by combining nembutal and menthol in the following way good results with *L. palustris* and *P. gyrina* are obtained. As many as 80 animals are placed in 150 ml. of tap water containing 1 ml. stock solution of veterinary nembutal (60 mgm. per ml.). The snails are left in the nembutal-treated water at room temperature for 1¼–1½ hr., and at the end of this time the soft parts are well extended. Then powdered menthol crystals are added (sufficient to cover the surface of the water), and the snails are refrigerated (4° C.) for 16–18 hr. in a capped jar. After this period of refrigeration, the snails can be fixed with the soft parts remaining in a well-extended position. When first placed in the fixative, slight movements of the tentacles may occur. During the period of relaxation in nembutal alone, the snails must be kept separated from one another and prevented from clinging to the sides of the container, otherwise interference with the extension of the foot may result. After the snails have been placed in the nembutal-treated water (before menthol is added), the time necessary for extension of the foot with cessation of movement is related to the size of the snail. *L. palustris* with a shell height of 6 mm. takes about 35 min., a 17 mm. snail about 55 min., and a 26 mm. snail about 65 min.

An interesting seasonal difference has been observed with *L. palustris* using this nembutal–menthol method of relaxation. Better results have been obtained with snails collected in the spring than with those collected in late summer and early autumn.

Occurrence of a 'Rare' Earthworm in Montgomeryshire

A preliminary survey of the Lumbricidae in Montgomeryshire has revealed large numbers of *Eisenia veneta* (Rosa) var. *zebra* (Michaelsen) in compost heaps, manure, under decaying wood and under stones at Caersws.

Michaelsen's specimens were from the Caucasus, and up to 1947[1] the only British records were two specimens from Limerick[2] and one specimen (?) from Colwyn Bay, North Wales[3]. In 1954, two specimens were sent to the British Museum (Natural History) from a compost heap in Staffordshire.

Var. *zebra* occurs, in Caersws, together with the common lumbricids of compost heaps, *Dendrobaena subrubicunda* (Eisen) and *Eisenia foetida* (Savigny); but has not been found in similar habitats in any of the neighbouring villages.

Three Zoopagales from Brackish Water

The Zoopagales are a small group of predacious fungi, at times placed in either the Mucorales or the Entomophthorales, but now more generally given ordinal rank. Most species prey on rhizopods (usually amoebæ); a few on eelworms, by adhesion to their rather sparse mycelium. Consequently they are most frequently found where these animals are active. Duddington[1] and Dixon[2] have recorded several species from compost heaps, decaying wood and moss cushions, and Juniper[3] from decaying animal dung, while Peach[4] restricted her searches to the aquatic habitats of pond and stream, which produced a remarkably rich flora.

So far no known recordings have resulted from saline habitats, but I have recently obtained three species from a salt-marsh in the Blackwater Estuary.

Samples were collected on three occasions during 1957 near Maldon, Essex; and consisted of decaying debris and roots from tufts of the grass *Puccinellia maritima*, and swards of the alga *Enteromorpha*. Both regions were covered normally at high tides, with salinity readings of covering water of 24·6–32·4 (normal sea-water 35). Material was plated on rabbit dung agar. (2 per cent agar in water rendered a pale straw colour by addition of filtrate from stewed rabbit dung.)

Fungus *a* was readily identified as *Stylopage rhabdospora* Drechs.[5] by spore measurements, conidiophore structure and nature of the haustoria. This species is also common in terrestrial and fresh water habitats in Great Britain.

Fungus *b* may be provisionally described as a variety of *Stylopage rhynchospora* Drechs.[6] from which it differed mainly in smaller conidial size and the very slight and non-evacuated terminal beak to the conidium. It has not been recorded before from any other habitat.

Neither of these fungi produced zygospores or showed any evidence of sexuality, though from non-saline habitats these species do so very readily.

Fungus *c* has been recorded on two separate occasions from the same locality and cannot satisfactorily be placed with any of the described species of *Zoopage*. It may therefore be found necessary to create a new species to accommodate it, if warranted by further studies of this seemingly complex genus. This fungus is very persistent, and is characterized by the conidial chains of regularly only four conidia, each up to 60μ long and the stalked haustoria with short dichotomously branched lobes. Although under close observation for four months, no signs of sexuality have appeared.

The three fungi briefly described preyed on small amoebæ (unidentified) 10–18μ in diameter, and appeared 14–24 days after inoculation on several plates of each series. None showed sexuality, though most of the Zoopagales readily do so.

A full description of these fungi will be published later, when further work on similar habitats has been completed.

I wish to record my appreciation to Mr. C. Everard who collected the samples and determined the salinity readings, and Dr. C. L. Duddington for his interest and advice.

Salmonellae in Uganda

THIS communication presents the preliminary results of an investigation into the carrier-rate of *Salmonellae* in zebu cattle arriving at the municipal abattoir of Kampala.

The cattle from which samples were collected had all been brought to Kampala from the Karamoja district, which occupies the north-eastern corner of the Protectorate and lies between latitude 1° 21′ and 4° 12′ N. and longitude 33° 20′ and 35° 0′ E. This district, which is administratively a closed area with relatively little contact with other territories, is the most primitive part of the Protectorate, and wild animals, including snakes and other reptiles, are present in considerable numbers.

Bacteriological examination was confined to fæces samples. The samples were collected by hand from the rectum a few hours after the animals had arrived at the abattoir. The samples were placed in a refrigerator within two hours of collection and cultured the following morning.

The method of isolation of *Salmonellae*, with a few minor modifications, was that used by Smith and Buxton[1] in the survey which they carried out in the United Kingdom. The types of *Salmonellae* isolated were identified by orthodox biochemical and serological methods, and the majority of the cultures were also sent to the Salmonella Reference Laboratory in England for confirmation.

Up to the present time, samples of fæces from 1,618 cattle have been examined and 33 samples, or 2·0 per cent, have been found to contain *Salmonellae*.

The species of *Salmonellae* encountered during the survey are as follows (the figures in brackets indicate the number of times each type was isolated) : *wien* (1), *heidelburg* (1), *shubra* (1), *stanleyville* (2), *ituri* (1), *makiso* (2), *oranienburg* (2), *newport* (1), *zega* (1), *orion* (1), *chandans* (2), *aberdeen* (1), *mishmar-haemek* (1), *brazil* (1), *cerro* (1), *chicago* (1), *kibusi* (1), *adelaide* (1), *nairobi* (2), *berkeley* (1), new type 1 (1), new type 2 (1), new type 3 (4), new type 4 (1), new type 5 (1).

The large variety of *Salmonella* types isolated and the complete absence of *S. dublin* is in striking contrast to the results of similar surveys undertaken in the United Kingdom, where in the course of five surveys[1–5] 250, or 96 per cent, of 260 *Salmonellae* isolated were *S. dublin* and the remainder consisted of four other types only.

The finding by other workers of various *Salmonella* types in lizards[6,7], snakes[8] and tortoises[9] might suggest that some of the types found during the present investigation had originated from reptiles or game. What their significance is in cattle this communication makes no attempt to decide. However, some of the types isolated have been implicated in the cause of disease elsewhere, and since, according to definition[10], all the known types are pathogenic for warm-blood animals, including man, the finding of a variety of these organisms in 2 per cent of the cattle entering an abattoir must be regarded as a potential danger to public health.

During the investigation five new types of *Salmonellae* were encountered. Their antigenic structures are as follows :

New type 1	1, 4, 12, 27 : z : z_6
,, ,, 2	16 : y : e,n,x
,, ,, 3	40 : z_{41} : 1,2
,, ,, 4	1, 42 : c : z_6
,, ,, 5	28 : 1, w : z_{10}

Types 1, 2 and 3 have been named *S. entebbe*, *S. kikoma* and *S. karamoja* respectively. Types 4 and 5 are still being examined at the Salmonella Reference Laboratory, and when their complete antigenic structures have been confirmed it is proposed to name the former *S. kampala* and the latter *S. moroto*.

It is intended to extend the survey to cover cattle other than those for slaughter and also to compare the carrier-rates in healthy and sick animals.

I wish to thank Dr. Joan Taylor, of the Salmonella Reference Laboratory, Colindale, for examining most of the *Salmonella* isolated. My thanks are also due to the Medical Officer of Health, Kampala, for allowing me to collect samples at the abattoir.

An Inexpensive Easily Constructed Fish-marking Tag

A simple inexpensive fish tag, after the style of the hydrostatic tag devised by Einar Lee, has been constructed as follows (Fig. 1). Transparent vinyl plastic tubing (Crystal Vinyl tubing No. 6*A*, supplied by Portlant Plastics, Ltd.) ⅛ in. int. diam. is cut in lengths of 2 in. One end of the tube is softened by heating near the edge of a very low Bunsen flame and then the walls are pressed together with large forceps. Dipping the forceps in cold water between each operation keeps them cold and thus increases the desired effect of welding the inner walls of the tube while minimizing distortion of the outer walls which cool more rapidly by contact with the cold forceps. Cooling the forceps also eliminates a tendency of the warm vinyl plastic to stick to them. A slip of white paper with the mark number and instructions in indian ink for the finder is next inserted and then the other end is closed. In one of the flattened ends a hole is made to take a 12-in. length of 0·65 mm. diam. monofilament nylon (sold for anglers as 27½ pounds or 12·5 kilos breaking strain). After insertion the nylon is knotted to form a loop. The cost of materials works out at less than 4*d*. a tag.

The tag is attached to the back of the fish, just anterior to the dorsal fin, in the case of pike and in front of the posterior dorsal fin in the case of pollack. A darning needle (which has the eye cut open on one side to hold the nylon) is used for drawing the nylon loop through the skin and the muscles, and a double looped knot is made to hold the tag in place. Darning needles are now used instead of medical suture needles which were originally used. The former are easier to insert and are considerably cheaper.

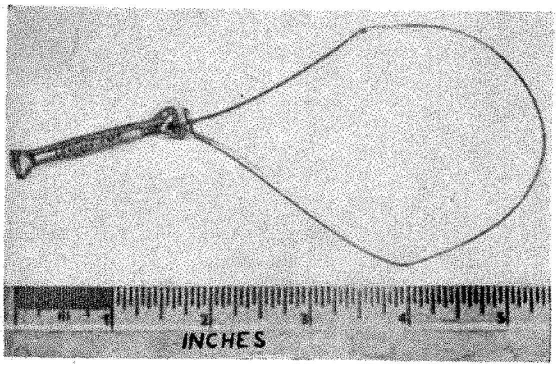

Fig. 1

We have used this tag in both freshwater (for pike) and sea water (for pollack). So far we have only had recoveries of pike; but these show that the tag is satisfactory. The wound made in the fish by tagging heals rapidly when this method is used and is completed in pike by the end of 48 hr. at water temperatures of about 10° C.

For freshwater work, at least, the tag has two advantages over the Einar Lee type; it is considerably less expensive and it is less conspicuous when submerged.

Chromosome Number of *Marsilea*

The genus *Marsilea* has not previously been investigated by modern cytological methods, and we have only the early investigations of Strasburger[1] and de Litardiere[2] using techniques which experience has shown[3] to be unreliable when applied to ferns. It is therefore perhaps of importance to record a clear count of $n = 20$ (see Fig. 1) for a race of *Marsilea minuta* from northern India. We believe this to be a diploid and have found $2n = 40$ in squashes of root tips. Other cytotypes are, however, also present in this species, notably a sterile triploid with $2n = 60$, which reproduces vegetatively but which is otherwise very like the diploid and frequently intermixed with it. Further observations on this material will be published elsewhere.

Growth Responses of *Fusarium oxysporum* to Metabolites of Some Rhizospheric Microflora of Egyptian Cotton Varieties

During studies on the rhizospheric microflora of different cotton varieties grown in Egypt, *Fusarium* wilt-resistant Ashmouni cotton variety rhizosphere proved to be inhabited by the highest percentage of strains of *Bacillus subtilis*, while susceptible Giza 26 cotton variety rhizosphere contained the highest percentage of a strain of *B. megatherium*[1].

Preliminary screening tests in which each of the bacterial strains was streaked against *Fusarium oxysporum* on either Dox's or soil-extract agar media have proved that *B. subtilis* strains were highly antagonistic to the wilt-inducing pathogen; the former spread rapidly and overgrew *Fusarium* mycelium and encircled it completely. Hyphæ of *Fusarium* were lysed and malformed. On the other hand, *B. megatherium* was stimulatory to *Fusarium* mycelial growth. The latter overgrew *B. megatherium* and produced comparatively very abundant conidia with abnormally large size and high septation.

Growth responses of *Fusarium oxysporum*, which proved to be a virulent pathogen causing wilt of either Karnak or Giza 26 cotton variety seedlings, to metabolites of either *B. subtilis* or *B. megatherium* on Dox's liquid medium have been tested by the following two methods: (1) germinative potentialities of *Fusarium* microconidia in hanging-drop cultures of either *B. subtilis* or *B. megatherium* metabolites; (2) growth of *Fusarium* mycelium on differently treated metabolites of either *B. subtilis* or *B. megatherium*. Filtrates of the test organisms were obtained from cultures of two ages, that is, 5- and 10-days old and were either cold-sterilized[2] or autoclaved. Control solutions using either Dox's liquid or water were also used.

The results (Tables 1 and 2) show that considerable suppressed germination of *Fusarium* microconidia and mycelial growth took place in response to either 5- or 10-days old culture filtrates of *B. subtilis* whether unheated or autoclaved. Ageing of culture or application of heat to its filtrate did not appreciably affect the latent period and final percentage of germination or the mycelial dry-weight of *Fusarium*. On the other hand, on using filtrates of *B. megatherium* from either 5- or 10-days old cultures, the final percentage germination of *Fusarium* microconidia rose to 100 per cent. At the same time, *Fusarium* mycelial growth was significantly higher as compared with that on control Dox's liquid media. A stimulatory factor for *Fusarium* microconidial germination and mycelial growth seems to be present in filtrates of *B. megatherium* the potency of which is not affected by heating. On the other hand, ageing of culture results in an increased stimulative effect over *Fusarium* mycelial growth.

Table 1. Growth Responses of *Fusarium* Microconidia to Metabolite-Filtrates of *Bacillus subtilis* and *B. megatherium* at 30° C.

Experimental medium	Age of culture	Filtrate treatment	Germinative capacities	
			Latent period	Germination (per cent)
B. subtilis filtrate	5 days	unheated	5 hr.	40
		autoclaved	5 hr.	40
	10 days	unheated	5 hr.	48
		autoclaved	5 hr.	50
B. megatherium filtrate	5 days	unheated	5 hr.	100
		autoclaved	5 hr.	100
	10 days	unheated	5 hr.	100
		autoclaved	4 hr.	100
Pure Dox's	—	—	2 hr.	90
Water	—	—	3 hr.	80

Table 2. *Fusarium* Mycelial Dry Weight (in mgm.) after 10 Days at 30° C. in Response to Differently Treated Metabolic-Filtrates of *B. subtilis* and *B. megatherium*. Pure Dox's Liquid is Diluted with Water and Metabolite Filtrates with Pure Dox's Liquid*

Experimental medium	Dilution (per cent)	Filtrate from			
		5-day old cultures		10-day old cultures	
		Un-heated	Auto-claved	Un-heated	Auto-claved
B. subtilis filtrate	100	33	35	29	30
	50	38	40	33	35
	25	45	48	38	41
B. megatherium filtrate	100	40	43	38	42
	50	73	77	80	85
	25	81	85	92	105

* Mycelial dry weight on 100 per cent pure Dox's liquid, 75 mgm.; on 75 per cent Dox's liquid, 61 mgm.; on 50 per cent Dox's liquid, 40 mgm.

Further work concerning the nature of the inhibitory anti-fungal metabolites of *B. subtilis* and the stimulatory factor of *B. megatherium* for *Fusarium* growth are still in progress. The former are probably of the nature of an antibiotic[3] while the latter seems to be a growth factor. Difference in the rhizosphere microflora of wilt-resistant and susceptible cotton varieties might explain why *Fusarium oxysporum* fails to invade Ashmouni cotton roots while its pathogenicity is established on susceptible Karnak and Giza 26 cotton varieties.

Thanks are due to Prof. A. H. Montasir for his unfailing help.

A Simple Technique for producing Fruit Bodies of Wood-destroying Basidiomycetes

In attempts to identify some of the many basidiomycete cultures isolated in our investigations of decay, we have tested a number of methods and have found that described here of the greatest value. It produces relatively large, identifiable fruit bodies from cultures representing a wide range of genera and families, and it has given consistent results in the hands of a number of workers, is not laborious, and requires no special equipment or materials.

The method involves establishing the culture to be identified on an enriched sawdust medium in a glass jar and then allowing it to grow through, and fruit on, a block of readily decayed wood incubated in diffuse daylight in a humid but not stagnant atmosphere.

The medium now used is a mixture of air-dry sawdusts (4–24 mesh) of seven timbers in the following proportions: *Pinus radiata* D. Don (sapwood), 25; *Eucalyptus obliqua* L'Herit. (sapwood), 25; *E. diversicolor* F. v. M., 10; *Acacia dealbata* Link., 10; *Nothofagus cunninghamii* Oerst., 10; *Rhizophora* sp. 10; *Ceratopetalum apetalum* D. Don, 10. (This

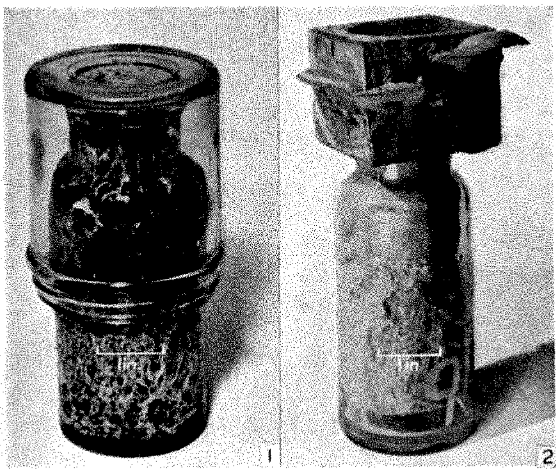

Fig. 1. Production of fruit bodies of wood-destroying basidiomycetes. 1, culture jar, with cover jar, after incubation at 25° C.; 2, culture jar showing fruit bodies of *Fomes gilvus* (Fr.) Lloyd on wood block

complex mixture, intended to ensure that fungi showing a strong host preference for fruiting in Nature will receive any accessory nutrients they require, is based on the general origins of our culture collection, and may be varied to reflect the origins of particular cultures.) The following nutrients are added to each 100 gm. of air-dry sawdust: 2·5 gm. maize meal; 1·5 gm. bone meal; 0·75 gm. potato starch; 0·2 gm. dried yeast; 0·5 gm. malt extract; 0·175 gm. casein hydrolysate; 0·0033 gm. thiamine hydrochloride. The first four are mixed in powder form with the dry sawdust; the last three are dissolved beforehand in the water used for moistening it. Sufficient water is added to saturate the sawdust particles without allowing free water to collect at the base of the culture jar, the amount required being determined for each batch of mixed sawdusts by draining saturated samples for 48 hr.

Enough moist nutrified sawdust is packed into a glass jar, 5¼ in. high and 2¼ in. wide, to come slightly above the mouth, which is then covered with an inverted wider jar (Fig. 1, 1) and the assembly autoclaved. An inoculum from a Petri-dish colony of the test fungus on malt agar is placed just below the surface of the sawdust and the jar incubated in darkness at 25° C. until a vigorous mycelium develops throughout the medium (Fig. 1, 1).

The inverted cover jar is then aseptically replaced by a sterile wooden block, 2¼ in. square by 1¾ in. high, with a ¾-in. deep well in the lower face to fit over the mouth of the jar, and a ¼ in. deep well in the upper face as a water reservoir (Fig. 1, 2). Blocks are usually either *Pinus radiata* sapwood or balsa, and are brought to a suitable moisture content for fungal growth (approximately 100 per cent for *P. radiata* and 300 per cent for balsa) before being autoclaved. It is essential that the block makes good contact with the top of the sawdust and fits tightly around the neck of the jar to prevent movement during subsequent handling. The block is covered with a sterile sheet of polyethylene film, gathered around the neck of the jar by a rubber band, to exclude contamination.

The culture jars are then incubated at laboratory temperatures (12–25° C.) in a shallow tank with a plate-glass lid, receiving abundant diffused light from the southern (polar) sky but no direct sunlight. Water in the bottom of the tank maintains a high humidity, and aeration is provided by bubbling compressed air through water in a flask and then into the tank. As soon as the fungus reaches the surface of the wood block, the polyethylene film is removed and the block is kept moist by adding water periodically to the well in its upper face. (Some contamination, usually *Penicillium* spp., may develop on the blocks, but has little adverse effect, though *Trichoderma viride* will often completely inhibit fruiting.) Jars are disturbed as little as possible, and if removed for inspection are replaced in the same position and orientation.

Fruit bodies are usually produced by 30–40 per cent of the culture jars included in each experiment, the time taken (after the jars are placed in the tanks) varying from 2 to 3 weeks, for *Schizophyllum commune* Fr., to 6 months or more, for *Fomes gilvus* (Fr.) Lloyd. They are usually of normal shape and coloration and of reasonably large size although some pileate species develop only a resupinate form. Fruit bodies may develop on any face of the blocks, but tend to be more frequent on the end grain and on the side facing the light; many develop from the lower face of the block. Satisfactory fruit bodies have now been obtained with species of *Polyporus*, *Coriolus*, *Trametes*, *Hexagona*, *Fomes*, *Ganoderma*, *Elfvingia*, *Poria*, *Dædalea*, *Merulius*, *Corticium*, *Peniophora*, *Coniophora*, *Stereum*, *Hydnum*, *Hymenochæte*, *Odontia*, *Lenzites*, *Lentinus*, *Paxillus*, *Schizophyllum* and *Hypholoma*; but it is not claimed that the technique described is suitable for all species of these genera, and research is continuing on further modifications and on other methods.

Comparative Chlorophyll Content of the Two Generations of Bryophytes

THE occurrence of chlorophyll in the sporophyte of Bryophytes has been noted by a number of investigators. Bold[1,2] has reviewed the older literature, and, by cytological studies on living material, has demonstrated chloroplasts and starch grains in the foot, seta and capsule of a number of species of both liverworts and mosses. In the liverwort, ***Riella americana***, "as the sporange approaches maturity, its color is much more deeply green than is that of the gametophyte"[3]. Douin[4] has examined the pigments of gametophytes of forty species of mosses belonging to twenty-eight genera, finding that all of them contain chlorophylls *a* and *b*, as in higher plants. In a comparative study of the sporophyte and gametophyte of five species of mosses, no qualitative differences in chlorophylls *a* and *b* or carotenoids were found[5].

It is the purpose of this communication to present quantitative results concerning the chlorophyll content of sporophytes and gametophytes of *Anthoceros carolinianus* Michx., *Polytrichum commune* L., and *Dicranum scoparium* (L.) Hedw. After macroscopic separation of the fresh plant material into gametophytic and sporophytic portions, the samples were weighed. Extraction of the pigments and spectrophotometric determination of the quantities of

Table 1

Species and generation	Chlorophyll *a*	Chlorophyll *b*	Total	Sporophyte/ gametophyte ratio
Anthoceros carolinianus				
Gametophyte	0·31	0·18	0·49	
Sporophyte	0·72	0·43	1·15	2·35
Polytrichum commune				
Gametophyte	0·07	0·05	0·12	
Sporophyte	0·19	0·10	0·29	2·41
Dicranum scoparium				
Gametophyte	0·13	0·09	0·22	
Sporophyte	0·21	0·15	0·36	1·64

chlorophylls present were performed in accordance with Official Methods of Analysis of the Association of Official Agricultural Chemists[6]. In Table 1, the chlorophyll concentrations found are expressed as mgm./gm. fresh weight.

While the much smaller sporophytes contain less total chlorophylls than the gametophytes, when comparisons are made on the basis of equal fresh weights, the chlorophyll concentration in the sporophytes exceeds that in the gametophytes by a factor of 1·64–2·41. These findings have an obvious bearing on the question of the nutritional relationship between the two generations.

Propagation of Cacao in Plastic Bags

THE basic physiological requirements for the vegetative propagation of cacao (*Theobroma cacao*) have been broadly worked out by Evans (1951) and may be summarized in that semi-hardwood cuttings in an atmosphere near 100 per cent relative humidity, at a reduced light intensity (15–20 per cent of the incident sunlight), given adequate aeration at the base of the cutting, will produce roots in the order of 70–90 per cent rooting efficiency.

A comparison of the costs of commercial propagation in Trinidad has been made by Murray and Bridge[1], and McKelvie[2] has shown that cacao may be propagated at greatly reduced cost, on a commercial scale, using sawdust-cored baskets[3] containing cacao cuttings, covered by polyethylene sheets. This method adequately dispenses with the expensive installation of commercial propagating bins, and considerably reduces water consumption and labour costs. Another method, making use of the properties of polyethylene, which restricts water-vapour diffusion but permits some gaseous diffusion, is being developed here. Cuttings are rooted entirely in plastic bags, transported to the field in the same fashion and afterwards established in the field.

The base of a semi-hardwood cacao cutting bearing 4–6 trimmed leaves is dipped in hormone solution. The base of the cutting is first placed in wet, leached sawdust laid in coconut fibre. The fibre is then folded around the base of the cutting and held in place with an elastic band. The final size of the sawdust and fibre 'ball' is about the size of a half-clenched fist. The cutting is inserted into a plastic bag (150 gauge, 20 in. × 11 in.), water (150–200 ml.) added and the neck closed with string. The bag is suspended under a shade of domestic cloth, and no further attention is required until root formation has occurred. The roots emerge through the fibre and may be readily seen through the plastic. The light-intensity, calculated by means of an actinograph, is approximately 7 per cent of the incident sunlight, but is not critical over wide limits providing the light is diffused.

The cutting is transported to the field in the bag and planted under heavy shade with the roots still enclosed in the fibre. The surplus water from the plastic bag is tipped over the plant and the bag is inverted afterwards over the cutting with the mouth of the bag lying loosely upon the soil surface. Two banana leaves, which provide local shade, are arranged in the form of an inverted V over the cutting, with the petioles firmly pressed into the soil. Natural drying-out of the banana leaves permits progressively more light to fall on the cutting. After 4–5 days, the bag is removed and re-used for further propagation. The purpose of the inverted bag is to reduce transpiration and replaces the conventional hardening procedure. The probable reason why success is achieved by this method is that the roots of the cutting are intimately interwoven with the wet fibre and sawdust, which retains moisture for a considerable time during the critical period when the roots are becoming established in the soil.

The rooting percentage in the bag is of the order of 80–90, depending upon the clone, and establishment in the field about 60–70 per cent of the cuttings set in the bags. Plants of the more vigorous clones are ready for planting 22 days from setting.

The advantages of the method are many. The plastic bag costs 2½*d.* and may be used a number of times without deterioration. Labour charges and initial installation are negligible when compared with conventional methods. Plants are introduced into the field more quickly and are very easily transported by hanging the bags from wires in a vehicle. Furthermore, drying-out, which is frequently observed with plants in baskets transported over long distances, does not occur. The combined weight of a plant and basket is between 3½ and 4 lb. as compared with 1 lb. for a plant in a plastic bag. One man may carry up to 20 plants in bags without difficulty, whereas he is restricted to two basketed plants owing to the weight and shape. This means that inaccessible bush areas may be more readily planted with clonal cacao. Skilled labour is not required at any stage in the process, and normal care is all that is required at planting.

Further work is being conducted on the storage of plants in bags containing a nutrient solution, and a full account will be published elsewhere.

Thanks are due to Mr. G. W. Smith for the measurements of light-intensity using the actinograph.

Saturday, March 1

British Interplanetary Society (in the Tudor Room, Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Prof. G. A. Witfield: "The Guidance and Control of Long-Range Vehicles".

British Glaciological Society (joint meeting with the Scott Polar Research Institute, at the Scott Polar Research Institute, Lensfield Road, Cambridge), at 8.30 p.m.—Mr. R. J. E. Brown: "Permafrost in Canada—Its Nature, Distribution and Influence on Northern Development".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturers (2) (honours graduates, preferably with some research experience in physical, inorganic or physical-organic chemistry) in Chemistry—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (February 28).

Professor (with high academic qualifications in engineering with teaching and research or industrial experience) of Applied Mechanics at the Royal Naval College, Greenwich—The Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting Ref. No. 4808/58 (March 4).

Assistant Lecturer in Geography; an Assistant Lecturer in Geology; and an Assistant Lecturer in Physics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 8).

Assistant Lecturer or Lecturer in the Department of Pure Mathematics—The Registrar, The University, Liverpool (March 8).

Lecturer in Geology at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 10).

University Lecturer (preferably with qualifications in applied thermodynamics) in Mechanical Engineering—The Secretary, The University, Aberdeen (March 11).

Assistant Lecturer (preferably with special qualifications in algebra and/or geometry) in Mathematics—The Secretary to the Council, Westfield College (University of London), Hampstead, London, N.W.3 (March 12).

Assistant Lecturer in Near Eastern Archæology—The Registrar, The University, Manchester 13 (March 15).

Assistant Lecturer or Lecturer (with special interests in sedimentation) in the Department of Geology—The Registrar, University College, Singleton Park, Swansea (March 15).

Experimental Officer (with a degree in chemistry or agricultural chemistry or equivalent qualifications), to carry out chemical analyses of soils and plants—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (March 15).

Professor or Reader in Agriculture—The Registrar, The University, Nottingham (March 15).

Research Assistant (graduate, with research experience) in the Department of Physics, to take part in research, under the direction of the Head of the Department, leading to the development of solid state image amplifiers; and an Assistant Lecturer in Geography—The Registrar, The University, Hull (March 15).

Lecturer or Assistant Lecturer in Mathematics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, March 20).

Assistant Lecturer or Lecturer in the Department of Pure Mathematics—The Registrar, The University, Birmingham 15 (March 24).

Senior Research Fellow and Research Fellow in the Department of Theoretical Physics, Research School of Physical Sciences, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 28).

Imperial Chemical Industries Research Fellows in Chemistry, Biological Chemistry, Engineering, Pharmacology, Physics or related subjects—The Registrar, The University, Bristol (March 30).

Lecturer and an Assistant Lecturer in Physics—The Registrar, The University, Hull (March 31).

Lecturer or Assistant Lecturer in Agricultural Botany at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 31).

Plant Geneticist (preferably with some research experience) in the Plant Breeding Section of the Department of Agronomy, Waite Agricultural Research Institute, to investigate factors affecting the quality and yield in barley and their mode of inheritance and to apply them in a barley breeding programme—The Registrar, University of Adelaide, Adelaide, South Australia (March 31).

Research Fellow (zoologist, with interests in marine biology) in the Department of Zoology—The Registrar, University College, Singleton Park, Swansea (March 31).

Imperial Chemical Industries Research Fellow in Chemistry or Physics—The Registrar, The University, Leicester (April 9).

Assistant or Associate Professor in the Department of Entomology—Head of the Department of Entomology, University of Alberta, Edmonton, Alberta, Canada (April 15).

Chair of Physics in the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 15).

Senior Lecturer or Lecturer in Epizootiology in the Faculty of Veterinary Science, University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 15).

Senior Lecturers or Lecturers in Mathematics, Geology, Zoology, Agricultural Chemistry, Engineering Mathematics, Mechanical Engineering, and Architecture at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 15).

Senior Lecturer (preferably with special qualifications in numerical analysis) in Mathematics at Victoria University, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, April 30).

Assistant Conservators of Forests (with a university degree in forestry) in the Western Region of Nigeria—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.61/410/01.

Assistant Professor (preferably with the Ph.D. degree or equivalent) in the Department of Mechanical Engineering—The Department of Mechanical Engineering, University of Vermont, Burlington, Vermont, U.S.A.

Head (with qualifications, teaching and research experience necessary for recognition as a teacher of the University of London) of the Department of Metallurgy—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Lecturer (preferably with experience and interest in experimental techniques) in Aeronautical Structures—Professor of Aeronautical Structures, Department of Aeronautics, Imperial College of Science and Technology, London, S.W.7.

Scientific Officer (with an honours degree in biochemistry, chemistry or physiology, and preferably with postgraduate experience) with the East African Trypanosomiasis Research Organization, Tororo, Uganda, to undertake research on the physiological, biochemical and/or chemical aspects of trypanosomiasis related especially to the assessment of the efficacy and toxicity of new trypanocidal drugs in East African cattle—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.195/198/013.

Senior Lecturer (honours graduate, preferably with research and/or industrial experience) in Physics—The Registrar, Hatfield Technical College, Hatfield, Herts.

Systematic Botanist and Ecologist (with an honours degree in botany and at least two years research experience, preferably in ecology; or an honours degree or equivalent in agricultural science plus two years completed postgraduate training in botany, preferably with an ecological bias) in Sierra Leone, to carry out ecological studies appertaining to agricultural and forestry problems (including the maintenance and enlargement of a herbarium)—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/15/012.

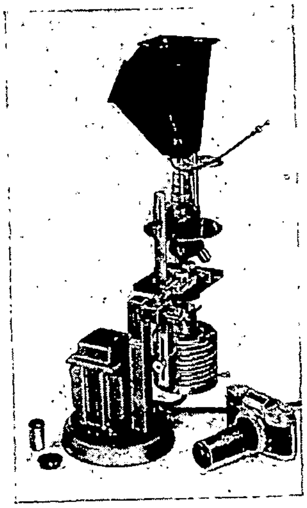
Britex Projection Microscope

with

CAMERA ATTACHMENT

Illustrates still another purpose to which this unit can be successfully applied and which clearly demonstrates the instrument's versatility and usefulness in industry, research and education.



FIVE MAIN USES :
- Projection in daylight.
- Projection on to a screen.
- Drawing of specimens.
- Examination of specimens in liquids.
- Use as an ordinary microscope.

Fuller details gladly sent on request.

LECTURES AND COURSES

COLLEGE OF AERONAUTICS

The Board of Entry of the College invites applications from suitable candidates for the two-year course which begins in October, 1958, and ends in June, 1960. The course is intended for selected students of graduate standard. Candidates who do not possess a university degree may offer alternative evidence of educational attainment, for example, a good higher national certificate with a satisfactory record of apprenticeship or equivalent experience in industry. All applications are considered by the Board of Entry which may call candidates for interview. The College, a postgraduate institution, is devoted to the study of aeronautical science and engineering. The curriculum covers the five main subjects of aerodynamics, aircraft design, aircraft electrical engineering, aircraft propulsion, and aircraft economics and production. Instruction in the first year is designed to provide all students with a broad background of knowledge in all these subjects, with opportunity for limited specialization in two or three of them. In the second year students specialize more particularly, usually in one subject. The teaching in the syllabus is designed to fit students for a career in either aircraft or guided weapon engineering. Experiments in the air are an important part of the work, both in the first year when all students take part in them and in the second year when they are linked to the specialist work of the departments. Students who satisfactorily complete the course receive the Diploma of the College.

Further particulars and details of the procedure for enrolment may be obtained from the Warden, The College of Aeronautics, Cranfield, Bletchley, Bucks.

UNIVERSITY OF LONDON: A COURSE of three lectures entitled "Physics as Geometry—the Present Status of Einstein's Programme" will be delivered by Professor John A. Wheeler (Princeton) at 5.30 p.m. on March 3, 5, and 10 at King's College, Strand, W.C.2. Admission free, without ticket.—James Henderson, Academic Registrar.

UNIVERSITY OF LONDON: A COURSE of three lectures on "Endogenous Diurnal Periodicity in Plants and Animals"; (i) "The Internal Clock System of Plants and Animals"; (ii) "The Phenomenon of Time Measurement in Photoperiodic Reactions"; (iii) "The Role of Yellow Pigments in Phototropic and Phototactic Movements" will be delivered by Professor E. Bünning (Tübingen) at 5.30 p.m. on March 4, 5, and 7 at King's College, Strand, W.C.2. Admission free, without ticket.—James Henderson, Academic Registrar.

UNIVERSITY OF LONDON: A COURSE of two lectures on (i) "Bacterial Endotoxins (Lipopolysaccharides)—Chemical and Immunological Aspects"; (ii) "Bacterial Endotoxins—Biological Activities and Investigations on their Mode of Action" will be delivered by Professor O. Westphal (Freiburg) at 5.30 p.m. on March 3 and 5 at the Westminster Medical School (Meyerstein Lecture Theatre), Horseferry Road, Westminster, S.W.1.—Admission free, without ticket.—James Henderson, Academic Registrar.

UNIVERSITY OF LONDON KING'S COLLEGE

CHEMICAL ENGINEERING

Applications for places next October in the postgraduate one-year course for the College Diploma should reach the Registrar, from whom particulars and forms may be obtained, by March 15.

The College offers Shell Studentships of the value of £375, with free tuition and examination fees. Applications for these should also be in by March 15.

This course is approved by the D.S.I.R. for Advanced Course Studentships. Applicants interested in these should inform the Registrar of the College by February 24.

King's College London,
Strand, W.C.2.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S.W.3

DEPARTMENT OF GEOLOGY

Head of Department: W. E. Smith, M.Sc., F.G.S.

An advanced evening course of six lectures on "Hydrogeology and Water Supply" will be given by Dr. J. Ineson on Friday evenings, 7 to 8.30 p.m., commencing May 2, 1958. The course is intended for geologists working on water supply problems and engineers with a basic knowledge of geology.

Further particulars can be obtained from the Head of the Department of Geology.

UNIVERSITY OF LONDON: A COURSE of four lectures entitled "Acoustic and Magnetic Effects in Compressible Shear Flow" will be delivered by Professor H. W. Liepmann (California Institute of Technology) at 5.30 p.m. on March 3, 5, 10 and 12, at Queen Mary College (Stern Hall), Mile End Road, E.1. Admission free, without ticket.—James Henderson, Academic Registrar.

OFFICIAL APPOINTMENTS

PETERBOROUGH JOINT EDUCATION BOARD

PETERBOROUGH TECHNICAL COLLEGE SCIENCE LABORATORY STEWARD

Required in April, a Science Laboratory Steward to take charge of stores and equipment in Chemistry, Physics and General Science Laboratories to be opened in April. Salary in accordance with the National Joint Council's Miscellaneous Scales, Grade IV, i.e., £540 by £20 to £620.

Application within ten days, by letter, to the Chief Education Officer, Education Offices, Town Hall, Peterborough.

McMASTER UNIVERSITY

POST-DOCTORAL FELLOWSHIPS IN PHYSICS

Applications are invited for National Research Council and other Post-Doctoral Fellowships tenable in the Department of Physics, McMaster University. Successful applicants may choose to work full-time on their research or to supplement their research with a modest amount of lecturing.

Inquiries and applications should be addressed to Professor H. E. Duckworth, Chairman, Department of Physics, McMaster University, Hamilton, Ontario, Canada.

UNIVERSITY OF EDINBURGH AND HERIOT-WATT COLLEGE

JOINT DEPARTMENT OF CHEMICAL TECHNOLOGY AND CHEMICAL ENGINEERING

Applications are invited for either a Lectureship or an Assistantship. Lectureship: the initial salary will be at a point on the scale £900 to £1,650 per annum, according to qualifications and experience. It is hoped to appoint a man who will be active in some field of chemical engineering research of his own choice. Assistantship: the initial salary will be in the range £700 to £850 per annum. Teaching duties will not be heavy and the Assistant may engage in research for a Ph.D. Both posts are subject to superannuation, and family allowance will be payable where applicable. The successful applicant will be expected to take up duty on October 1, 1958. Applications will be considered from chemical engineers, physicists, chemists or mechanical engineers, or from mathematicians who have experience in applied science.

Further particulars may be obtained from the undersigned, with whom applications (four copies), giving the names of two referees, should be lodged not later than March 24, 1958. (A candidate from overseas may submit one copy of this application.)

CHARLES H. STEWART,
Secretary to the University.

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF PHYSICS

Applications are invited for appointments as Lecturer, Assistant Professor, Postdoctorate Fellow and Research Assistant in the Department of Physics. The vacancies have been created by the rapid expansion of the university. They are mainly in the fields of nuclear physics, optical spectroscopy, solid state physics and geophysics. Applicants should have an honours degree in physics and, except in the case of Research Assistants, a Ph.D. degree. They should not be more than 30 years of age and should be available in September, 1958. There are also Teaching Assistantships available to help students who wish to pursue graduate work towards a Ph.D. degree.

Applicants wishing fuller information regardin any of these positions or awards should write t G. M. Shrum, Head, Department of Physics, Uni versity of British Columbia, Vancouver, B.C., Canada.

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF AGRICULTURE

The Council invites applications for appointment as Professor or Reader in Agriculture. The appointment carries with it the Headship of the Department of Agriculture which is one of the four Departments of the Faculty of Agriculture located at the School of Agriculture, Sutton Bonington. Salary: Professor £2,450; Reader within the scale £1,650 by £75 to £2,150, with supe nuation (F.S.S.U.) and family allowances.

Conditions of appointment and form of app cation, which should be returned by March 15 1958, from the Registrar.

UNIVERSITY OF LONDON: APPLICATIONS are invited for IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWSHIPS in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology, Physics. The Fellowships will be within the range of £800 to £1,000 per annum and will normally be tenable from October 1, 1958, for three years. Family allowances and F.S.S.U.—Detailed regulations and application forms may be obtained from the Academic Registrar, University of London, Senate House, W.C.1. Applications must be received not later than April 30, 1958.

UNIVERSITY OF LONDON: APPLICATIONS are invited for a TURNER AND NEWALL RESEARCH FELLOWSHIP in Engineering, Inorganic Chemistry, or Physics. The Fellowship will be within the range of £800 to £1,000 pe annum and will normally be tenable from Octobe 1, 1958, for three years. Family allowances an F.S.S.U. Detailed regulations and applicatio forms may be obtained from the Academic Registrar, University of London, Senate House, W.C.1. Applications must be received not later than April 30, 1958.

PROTEIN CHEMIST OR PHYSICIST, TO work on immunological problems. Preferably Ph.D. or equivalent research experience. Salary £750 to £850. F.S.S.U. Appointment for one year with possibility of extension.—Apply in writing to the Secretary. The Wright-Fleming Institute of Microbiology, St. Mary's Hospital Medical School, Paddington, W.2.

BATTERSEA COLLEGE OF TECHNOLOGY

BATTERSEA PARK ROAD, LONDON, S.W.11

Principal: R. W. West, C.B.E., D.Sc., A.R.C.S., F.R.I.C., F.I.R.I.

DEPARTMENT OF METALLURGY

Head of Department: L. W. Derry, B.Sc.(B'ham.), M.Sc.(Tech.)(Vict.), F.I.M., M.I.M.M., A.F.R.Ae.S.

POSTGRADUATE COURSES IN CRYSTALLOGRAPHY

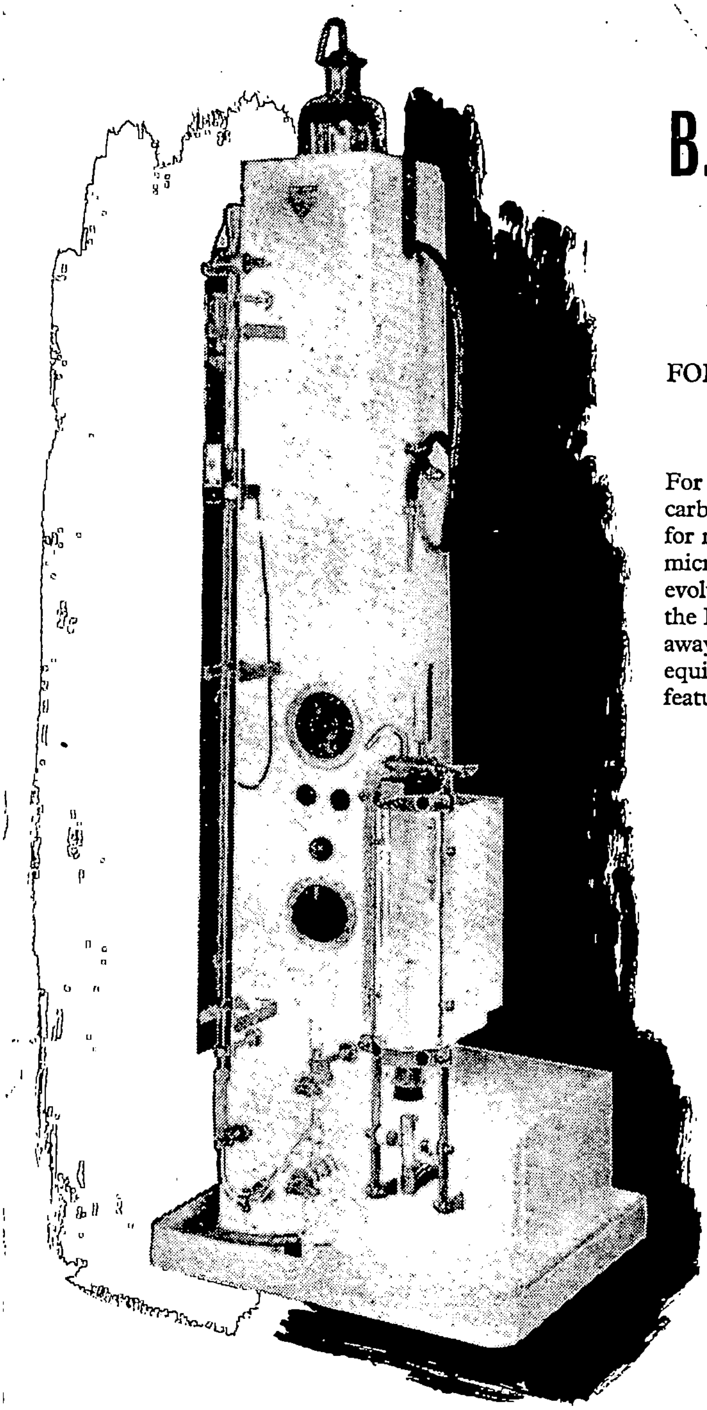
Postgraduate courses in Crystallography leading to the examinations for the degree of M.Sc. of the University of London or the postgraduate diploma of the Battersea College of Technology, D.C.T.(Batt.), will be held in the Metallurgy Department commencing in September, 1958.

The duration of the courses will be one session.

The entry qualifications to the courses will be those laid down by the University of London or the College of Technology, respectively.

Intending students are eligible to apply for D.S.I.R. Advanced Studentships, applications for which must be made before March 31, 1958.

Applications for entry to the course should be made to the Head of the Metallurgy Department.



B.T.L. Van Slyke Apparatus

FOR STANDARD MANOMETRIC GAS ANALYSIS

For the determination of carbon dioxide or carbon monoxide in blood, plasma etc. and for many applications in biochemistry and micro-analysis where an amount of gas evolved from a fluid has to be measured, the B.T.L. Van Slyke Apparatus is far and away the most advanced and convenient equipment now available. The principal features are:

Shaking motor with variable speed control up to 200 per minute.

The fine capillaries employed give extremely accurate control of the mercury.

Graduated manometer with illuminated meniscus reader.

Shaking pipette, with sloping shoulders to avoid trapping gas bubbles.

Glass water-jacket, with thermometer, illuminated from rear so that pipette is clearly seen.

Synchronous motor-operated timer and alarm buzzer can be fitted as optional extra.

TECHNE TEMPUNIT

The Techne Tempunit is a self-contained constant temperature control for fitting to any vessel.

- Indicating Thermostat.
- Patented pneumatic control.
- ± .05°C. in unlagged 4 gallon bath over the range, room temperature to 90°C.
- Circulation to external apparatus.
- Brushless silent motor.
- Rugged solid drawn 1000w. heater.
- Efficient stirrer.
- Available for 200/250v., 50 cycle a.c. or 100/120v., 50/60 cycle a.c. supply.

accurately WE MEASURE

EVERY ASPECT OF VACUUM APPLICATION

AND *SPEEDILY* LOCATE THE TINIEST VACUUM LEAK!

With the most comprehensive range of precision vacuum gauges and ultra-sensitive leak detectors in the world!

THERMIONIC IONISATION

RANGE: 10^{-2} to 10^{-10} mm. Hg.
For the *continuous* indication of the highest vacua.

KNUDSEN

RANGE : 10^{-4} to 10^{-7} mm. Hg.
The only high vacuum gauges measuring absolute pressures of gases or vapours.

PENNING-TYPE IONISATION

RANGE: 5×10^{-3} to 10^{-5} mm. Hg.
A gauge in the high vacua range with valuable operational advantages for industrial service.

COMBINED VACUUM GAUGE

RANGE: 0·5 to 10^{-5} mm. Hg.
A combined gauge covering the Penning-type ionisation and the Pirani-type. Particularly valuable for industrial vacuum systems.

LKB "AUTOVAC" (LKB-Produkter)

RANGE : 0·001 to 70·0 mm. Hg.
A new Pirani-like gauge which extends to higher pressures than those normally associated with this gauge.

McLEOD

RANGE: 10·0 to 10^{-6} mm. Hg.
The classic gauge which retains its supremacy as the standard reference gauge against which all other gauges are calibrated.

"VACUSTAT" MINIATURE McLEOD

RANGE: 10·0 to 10^{-3} mm. Hg.
Only 9 in. high . . . in various forms for bench use . . . control panels . . . fusing to glass systems.

BAROMETRICALLY COMPENSATED CAPSULE DIAL GAUGE

RANGE: 760 to 1·0 mm. Hg.

Also a complete range of oil and mercury manometers

For better vacμμm service . . .

BRITISH PHARMACOPŒIA 1958

This new edition of the Pharmacopœia supersedes, as from September 1, 1958, the British Pharmacopœia 1953 as amended by the Addendum 1955. The book has been completely revised and greatly extended. It now contains 826 monographs of which 160 deal with substances and preparations new to the Pharmacopœia.

The monographs provide standards and methods of test for a wide range of inorganic and organic compounds, synthetic chemicals, antibiotics and biological substances and also for preparations, including tablets, injections and ointments.

There are 27 Appendices providing descriptions of chemical, physical and biological assay procedures including:

Quantitative tests for arsenic and lead.
Determination of melting-point, boiling-point, viscosity and light absorption.
Determination of ash, alcohol content, and total solids.
Chemical analysis of fixed and volatile oils.

The Appendix on biological assays and tests includes a section on the design and accuracy of biological assays and methods for antibiotics, serological and bacteriological products, hormones, etc.

LOCAL ADMINISTRATION IN A TECHNOLOGICAL AGE

ADDRESSING the Association of Municipal Corporations last September, Sir John Wolfenden asked what would be lost if the whole panoply and paraphernalia of local government were scrapped and the administration of Great Britain undertaken by local agents of the central authority. The question deserves a considered answer before, and not after, judgment is passed on the Local Government Bill now before Parliament; the Windscale incident alone is sufficient reminder that the issues are not so remote from the scientist and technologist as might appear at first sight. That the question should be asked at all is evidence that a well-known passage in de Tocqueville might not pass unchallenged to-day: "Local assemblies of citizens constitute the strength of free peoples. Town meetings are to liberty what primary schools are to science; they bring it within the people's reach, they teach men how to use and enjoy it. A nation may establish a system of free government but without the spirit of municipal institutions it cannot have the spirit of liberty".

In this passage de Tocqueville was concerned with the function of local government in civic self-education and, as was made clear in the three White Papers which preceded the Bill, and again by the Minister of Housing and Local Government, Mr. H. Brooke, in moving the second reading of the Bill on December 9, that is a main purpose of the Bill—to create conditions in which local government can gain new vitality. As was said in the first of the White Papers, on "Areas and Status of Local Government Authorities in England and Wales": "The test of any system of local government in this country should be whether it provides a stable structure, capable of discharging efficiently the functions entrusted to it, while at the same time maintaining the local democratic character". In introducing the Bill, Mr. Brooke rejected, however, the argument of this White Paper that comprehensive reform is unnecessary, and claimed that the Bill, while retaining the broad lines of the existing system of local government as the framework of re-organization, points the way towards achieving effective local government in present circumstances without going too far and causing rigidity. The financial provisions, in particular, he said, are designed to strengthen the local character of local government by enabling local authorities to exercise greater responsibility over the expenditure of money in their own areas, and in the provisions relating to the area and status of all concerned, the local authorities, the two Local Government Commissions and the Minister are enjoined to secure "effective and convenient local government".

During recent years, much public discussion besides the series of White Papers has prepared the way for the Bill. Mr. H. Maddick, for example, in an article in the *Westminster Bank Review* entitled "Local Government—Partner or Agent?", some three years ago discussed essentially this question put by Sir John Wolfenden. Mr. Maddick unhesitatingly answered "Much" to Sir John's question and argued that, in spite of the admitted dangers, in most areas the quality and nature of the local services should be left to the action of local inhabitants. It is a most cogent argument for a continuing, viable system of local government that it teaches citizens how democracy works in a context that is not too wide and too complex for them to understand; it provides them with expert advisers who are familiar with all the local problems and peculiarities; and it brings them up against the cost of providing services.

It is significant, in view of the trend of Opposition criticism in the House of Commons of the present Bill, that Mr. Maddick particularly specifies the value of the much wider realization of the cost of education to be secured in this way, and he would obviously support the Government's policy to place education, so far as possible, under local control; nevertheless, he recognizes the difficulties over finance and stresses the importance of providing local authorities with alternative sources of finance, at once adequate, resilient and independent of Government sanction. He also supports the principle of block grants rather than percentage grants, and suggests that more could be done to bring the experience of one locality to the notice of the council and electors of another. Further research into such questions is needed which, he suggests, could be the main function of a central department.

The most casual reading of the debate in Parliament on the second reading of the Bill indicates the value of such independent academic opinion. Concern about the possible effect of the Bill on education led to attacks which were pressed with complete disregard of the impossibility of effective reform of local government unless the local authorities were entrusted with greater responsibilities and, *ipso facto*, with the possibility of making mistakes. Yet Mr. Frank Bower, in an article in *Progress* last year, written after the publication of the first of the White Papers, argued convincingly that the present financial subservience to the central Government needs to be replaced by a real independence and correspondingly by a real responsibility to the ratepayers. A revision of the functions of central and local government in this sense would eliminate much waste of effort and money in the detailed control of local authorities from Whitehall, and by giving new vitality and independence to the local authorities would also encourage responsible citizens to undertake the work of councillors.

Once again, Mr. Bower recognizes the difficulty over education, which represents some seven-eighths of all expenditure on the dozen services covered by the Government's proposed block grant; but he points out that while the central Government should assist the local authority by a block grant to provide a minimum standard of service, the authority could be left to add to that standard at its discretion and its own cost. Mr. Geoffrey Lloyd has indeed affirmed most specifically his intention of seeing that standards are observed. It is no part of the Government's policy, he said in the debate on December 10, to reduce the central Government's grant aid to local authorities' expenditure on education or to freeze the contribution at its present level; on the contrary, the Government's policy is to increase that contribution in accordance with the conditions laid down in Clause 2 of the Bill. In this speech, Mr. Lloyd laid bare what appears to be the hard core of the opposition to the Bill—the fear that the local authorities will be unwilling or unable to provide the money required. It is clear, as Mr. Lloyd pointed out, that the changes proposed in the Bill will involve education (and other) committees much more closely in explaining and defining their proposals to their councils and finance committees and to local public opinion, and this is undoubtedly all to the good. If indeed local authorities are not to be trusted to administer so vital a service and fail to seek the essential understanding and support from local public opinion, they will frustrate the national policy approved and provided for by Parliament; in that event we may well turn to the further question asked by Sir John Wolfenden: Is local government in danger of ceasing to be government at all?

In the debates on December 9 and 10 the Opposition seemed to take the view that local government has already gone far towards becoming simply a system of local administration of national policies; but there is substance in Sir John's contention that local agents of a central authority are not necessarily less sympathetic than local authorities to local needs and can be just as good from the point of view of sheer efficiency. The retention of local government cannot be justified on such grounds, least of all when local councils are increasingly content to behave as agents of the State, rather than as independent bodies, serving in matters of national concern as its junior partners but carrying the primary responsibility for social welfare in local affairs. Throughout the debate, the chorus was not of dependence on Government grants but of the inadequacy of those grants: the manifest loyalty of local councillors was not so much to local government itself as to their own administrative unit. Yet until local government as such receives not merely lip service but also the devotion and firm support which can break the present vicious spiral and over-ride the prejudices and obsolete patterns which have caused its structure to lose all touch with rapid changes of twentieth-century life, there is no hope of effective reform. Independent and impartial observers and students have pointed the way, although social and technical changes have enormously extended both the scope and scale of the services which local authorities are required to administer. But the whole task would still be well within the competence of local government, organized on a two-tier basis, if its administrative units had been adapted to the radical changes in the pattern of town and country life and social habits, and if Parliament had conceded the financial resources of independence.

This, however, is not to assert that local authorities and local electorates are enlightened enough about national needs for a service so important as education, for example, to be entrusted more closely to their responsibility; but without such trust and responsibility the prospect of progress is slight. Indeed, local government reform fundamentally is a task of education—of awakening and holding the interest and loyalty of the average citizen, of bringing him to an awareness of the issues that will lead him to vote the necessary supplies and to resist the blandishments of those who wish to bring party political views to bear. For the sound administration of both local affairs and national affairs in this technological age, the average citizen must be sufficiently aware of such issues.

That is the real reason why local government is the concern of those who wish to see the fullest public benefit derived from the application of scientific knowledge. Effective delegation of local issues to the maximum extent is the only way of easing the pressure on the central administration and making the task of central government possible among the complexities of to-day without resort to autocracy or dictatorship. Local administration is essential, moreover, not simply to lighten the burden at the centre but also for the value of the contribution it can make to efficient government itself, and to the preservation of the personal touch and awareness of human issues; it can keep the central administration itself sensitive to public needs and views, as well as stimulate a closer interest on the part of the citizen himself, and a sense of being able to influence his own affairs.

One difficulty is that of reconciling a shift of responsibility with the needs of good administration, when most functions call for highly specialized staff and some may require substantial resources and can be administered efficiently and economically only on the basis of large areas or populations. Even here, however, as the experience of the Nature Conservancy and the National Parks Commission indicates, without local understanding and support it is difficult to achieve the ends of national policy or to eliminate real or imaginary clashes between local or sectional and national interests.

In principle, the Local Government Bill is sound. The block grant will make the local council a more impartial body and put more responsibility for getting value for money on those who make the decision to spend it. Provided the transitional period for redistribution of grants is not too protracted and some room is provided for experiment with incentive factors in weighting the block grant, any serious diversion of money from education is unlikely, and there is every prospect of much more effective elimination of waste.

At one extreme, local authorities are local government bodies performing local services to meet local needs. At the other, they are administrative agents for implementing locally a national policy which has been laid down by Parliament. Conflict arises when the local authority is required to raise for the latter purpose large sums of money for local resources, and it is the blindness of both major political parties to this ever since the National Parks Commission was established that is the real reason for legitimate doubts as to the efficacy of the present measures. There are adequate sanctions for the Minister to deal with those authorities which are reluctant to maintain standards, just as the proviso that the Minister may alter the boundaries of individual urban areas or groupings of areas when the responsible commission is unable to make appropriate recommendations may avoid the frustration that befell the earlier Local Government Boundary Commission.

Criticism there should and will be on points of detail, and it should also be recognized that in regard both to functions and areas the White Papers on which the Bill is based sought to bridge the considerable gap between what was needed and that on which the local authority associations themselves had been able to agree. Neither the Minister nor the Commissions should be unduly limited by that restricted measure of agreement, but should seek with imagination and courage to exploit to the full the opportunity of rebuilding democratic strength provided by this new widening of the areas of decision open to local government. Much hard and unprejudiced thinking is needed, to which the central Government itself and especially the Treasury has something to contribute, if the existing anomalies are to be removed and new strength and flexibility imparted to local finance. But at least we are shown the way forward to local institutions which could be kept abreast of changing conditions and values, and in which local needs are met by local decisions made increasingly in a context of real awareness of national problems in a technological age.

STEAM INTELLECT SOCIETIES

George Birkbeck

Pioneer of Adult Education. By Thomas Kelly. Pp. xii + 380 + 11 plates. (Liverpool: At the University Press, 1957.) 45*s*. net.

The Mechanics' Institutes of Lancashire and Yorkshire Before 1851

By Dr. Mabel Tylecote. Pp. x + 346 + 8 plates. (Manchester: Manchester University Press, 1957.) 37*s*. 6*d*. net.

CHARLES DUPIN, a French mathematician and naval engineer visiting Britain in 1816, was much struck by two brothers who worked in a bakehouse which they had equipped with portable gas-lights. In the intervals of baking bread, these two made a steam engine which they used in turn to make "des machines et des instruments de physique". Their uncle (who apparently owned the bakehouse) was neither amused nor interested; according to Dupin, "il préfère de beaucoup la boulangerie et la pâtisserie à la gazometrie et l'astronomie".

These baking brothers, who symbolized for Dupin the incubation of technological zeal in Britain, were neither an isolated nor a new phenomenon. As early as 1717 the weavers and artisans of Spitalfields were working out mathematical problems on their slates. In 1789, a group of young men in Birmingham began to earn for themselves the title of 'The Cast Iron Philosophers' from their habits of discussing mechanics and natural philosophy with foundry workers and others. In 1800, the geologist, Thomas Webster, was discussing, at the newly founded Royal Institution, "the application of science to the common purposes of life". In the autumn of the same year George Birkbeck, a twenty-four-year-old medical graduate of Edinburgh, enrolled seventy-five workmen for a course of lectures "abounding in experiments, and conducted with the greatest simplicity of expression and familiarity of illustration, solely for persons engaged in the practical exercise of the mechanic arts". The steam-intellect societies had begun. Technology-hungry artisans were, as Dupin rightly said, a portent. One of them, Timothy Claxton, was determined to form a "Society of Ingenious Working Mechanics . . . to study and improve the Arts of this Kingdom". It began in 1817 and lasted until 1820, when Claxton went to Russia. Four years later he appeared in Boston with an air pump and some apparatus.

The anastomizing threads of all this activity came together in 1823 when a mechanics' institute was founded in London. As Dr. Kelly, in his long-needed and well-documented biography, points out, Dr. Birkbeck was not the literal founder. That honour is reserved for a Fleet Street journalist and patent agent named J. C. Robertson. Yet the London Mechanics' Institution was based on Birkbeck's earlier work in Glasgow, the effects of which M. Dupin so much admired; and the London Mechanics' Institution was the real starting point of the mechanics' institute movement in Britain. Nine years after Birkbeck's death in 1841 there were 700 mechanics' institutes in Britain alone, catering for a membership of 120,000. More than 600 of these were in England.

Since more than a quarter of the total number of such institutes in England were in Yorkshire and another ninth in Lancashire, it is natural that a survey of these two areas should have been made. Dr. Mabel Tylecote's, begun more than thirty years ago, reinforces what has previously been suspected about the efficacy of these institutions. Nearly a hundred pages of her text are virtually proto-histories of the Manchester College of Science and Technology and of the Huddersfield Technical College. Of the latter in its days as a mechanics' institute she writes (p. 66), "There was not in Lancashire a success parallel to that of the Huddersfield Mechanics' Institute, or even, perhaps, to that of some of Huddersfield's neighbouring institutions".

Some of those who laboured in the cause were, incidentally, keen students of the history of technology: Henry Dircks of Liverpool and C. F Partington laboured in their spare time on such seventeenth-century figures as Hartlib and the Marquess of Worcester. Others, like James Hole, the secretary of the Yorkshire Union, looked out from existing institutions to an 'industrial university': "Inefficient as they may be as a means of industrial instruction", he wrote, "they afford the best instruments for introducing an improved system". That 'improved system' was to occupy the efforts of scientists and statesmen for the rest of the century and at each stage apathy, indifference, hostility and misunderstanding dogged their efforts.

Dupin's prediction to the mechanics of Paris that in the next twenty years "the conquests of science and industry in Great Britain [would] surpass those of all the generations which had given so much prosperity to her people" was, as we know, fulfilled. What we did not know, and do now, thanks to these meticulously careful and patient studies of Dr. Kelly and Dr. Tylecote, is the way in which the mechanics of those days took their instruction and their fun. For the Yorkshire Union was a regular Channel 9; Dickens and Emerson trod their lecture platforms as well as the local cognoscenti. They were the Royal Institutions of the plebs, as virile as those for whom they catered.

W. H. G. ARMYTAGE

AN ECOLOGICAL PERSPECTIVE

Biogeography

An Ecological Perspective. By Pierre Dansereau. Pp. xiii+394. (New York: The Ronald Press Company, 1957.) 7.50 dollars.

THE sub-title of this volume is more appropriate to its contents than the main title, for it is essentially a text-book of general ecology, containing but little of the traditional material of plant and animal geography. The principal sub-divisions indicate the scope of the work: history of biota; bioclimatology; synecology; autecology; and man's impact on the landscape. These form the five 'levels' of Prof. P. Dansereau's perspective, and within this framework he deals with all the more important aspects of the environmental relationships of living organisms. As he states, much of his ecological philosophy is derived from the Zurich–Montpellier school; it is not surprising that this should be so, for his mind is evidently given strongly to systematization.

In fact, Prof. Dansereau adopts a taxonomic approach to all aspects of ecology, descriptive and otherwise, for while he stresses that the crux of ecological thinking is in the holocoenotic point of view, his method of treating phenomena both static and dynamic is to dissect, define and classify. As a result his text is copiously subdivided, and studded with tabulations. This is undoubtedly a treatment admirably suited for the student seeking to gain some sort of grasp of this huge and inherently somewhat amorphous field; for him it has the all-important merits of clarity, apparent unambiguity and memorative value.

The demerits of this sort of treatment should not be overlooked, however; many issues are not to be resolved merely by classification and definition, and indeed such a process may create a mask for ignorance and obscurity. It is questionable, for example, whether even for an elementary student it is justifiable to present so cut-and-dried a view of the climax hypothesis as Prof. Dansereau does in his synecological section.

Be this as it may, bringing order to so wide a field in so compact a volume represents a fine achievement, even if the treatment involved in doing so is occasionally procrustean. Although as is to be expected the illustrative material is predominantly botanical, the width of example quoted is impressive, based as it is upon Prof. Dansereau's acquaintance with American ecology from tropics to arctic. The bibliography of more than 400 references supplies an excellent entry to ecological literature, notwithstanding its marked bias towards that of the New World.

A word must be said, also, about the illustrations. Like many recent North American text-books, this one makes frequent use of a cartoon-style of diagram which, at its best, is capable of lending an immediate force to a point and of registering it upon a reader more securely than many pages of text. The bulk of the diagrams are outstandingly successful, but one or two have reached a degree of over-elaboration which reduces them to a form of puzzle or intelligence test—sometimes, like those concerning the structural description of vegetation, merely to an exercise in memory.

A similar charge of over-elaboration may be levelled at some of the technical vocabulary. True, precise expression demands an adequate terminology, but it does little service to a subject to snow it under with polysyllables. In the introduction to his glossary, Prof. Dansereau notes the need to avoid calling a spade a geotome, but a sneaking sympathy with those who do so is surely shown when he himself refers to a long-day plant as a longidiurn and a short-day plant as a brevidiurn.

In summary, it may be said that this is a treatment of a wide and difficult subject which, by careful planning and avoidance of controversy, manages to be both comprehensive and concise. To the good teacher and the thoughtful student it should supply an excellent basis for a course in general ecology; but there is at least a risk that the very efficiency of the author's rationalizations of the subject-matter could tempt the mediocre to an under-estimation of its complexities.

J. HESLOP-HARRISON

SIXTH-FORM PHYSICS

New Intermediate Physics

By G. R. Noakes. Pp. viii+962. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1957.) 30*s.* net.

MR. G. R. NOAKES has a very high reputation as a writer of physics text-books for use in the sixth forms of public schools and grammar schools. The present work collects into one volume his previous books on separate branches of physics; but since two of these, on light and on electricity, were not easily adaptable, those sections have been completely re-written. The other sections have been somewhat modified so as to keep them within the comprehension of that increasing number of students who cannot be regarded as possible entrants for university scholarships, but who may nevertheless be valuable contributors, at a lower level, to the scientific man-power of the nation.

In his new section on light, the author uses both the real-is-positive and the new Cartesian conventions; this seems to augur the final—and very proper—victory of the latter. It would, indeed, be interesting to know whether any English university department of physics now uses the real-is-positive convention. The section has most of its discussions in terms of wave theory, which makes for greater interest than the rather bare bones of geometrical optics. The somewhat short treatment of the diffraction grating might have been expanded to answer explicitly the usual schoolboy question as to why more than two lines on the grating are necessary.

It is, however, in the section on electricity that Mr. Noakes is at his best. The arguments, which are remarkably ingenious, are based entirely on the M.K.S. system. Mr. Noakes takes trouble, by simple analogies, to make clear the relations and differences between lines of force and lines of induction, usually left very vague, in books of this standard, and in many others. It is pleasant, also, to find a short discussion of magnetic domains, which gives details of the structure of both antiferromagnetic and ferrimagnetic materials.

A few omissions have been noted; thus, the term 'enthalpy', coming into increasing use, does not appear in the index. A more striking omission is radioactivity, of which no mention in any form appears. A chapter on this subject is surely desirable, in view of its great importance, which has caused it to be introduced already into the syllabuses of some of the examining boards for the Advanced Level General Certificate of Education. A rather fuller account of Essen's experiments on the velocity of electromagnetic waves might have been given, since these are of much higher accuracy than the more usually described optical methods.

On the whole, the book may be commended as an excellent production, well worthy to rank with the author's previous works, and very good value for money. W. H. Dowland

THE PHASE RULE

Chemical Phase Theory

A Comprehensive Treatise on the Deduction, the Applications and the Limitations of the Phase Rule. By Prof. J. Zernike. Pp. xv+494. (Deventer: Kluwer's Publishing Co., Ltd.) n.p.

THE phase rule is physical chemistry *par excellence*; yet older physical chemists in industry cannot help feeling that the modern young recruit, bristling with university degrees and knowing his electronic theory and quantum mechanics inside out, is less well versed in the phase rule and its applications than his predecessors. This is doubly unfortunate, since not only does every chemical manufacturing process come up against the rule sooner or later, but the study of equilibria between phases and the construction of phase diagrams offer a wealth of intellectual delight that few other subjects, if any, in chemistry can surpass.

Good books on phase equilibria are few and far between, and the appearance of a new one can be regarded as something of an event. Once again the veteran is apt to hold the view, with some justification, that there is only one treatise on the subject worthy of consideration, namely that commenced by Bakhuis Roozeboom in 1901 and concluded by his successors Schreinemakers, Buchner and Aten. These books are now very rare, and any library or individual owning a copy of the complete work can be considered exceedingly fortunate. Any physical chemist desirous of winning the lasting gratitude of his peers could do no better than translate Roozeboom into English, and persuade an enterprising publisher to bring out a new edition.

It would not be fair to compare Prof. J. Zernike's 500 pages with Roozeboom. Nevertheless, "Chemical Phase Theory" is a very good book indeed. I prefer the rigorous thermodynamic proof using the partial molar Gibbs functions to the rather elementary proof adopted by Prof. Zernike in Chapter 1. The rigorous proof of the phase rule, however, cannot be appreciated without a good introduction to thermodynamics, and Prof. Zernike may have felt that this was outside the scope and aim of his book, which is to be, above all things, descriptive. The concept of the number of components of a phase system, which is often confusing to the beginner, is very well explained. The fact that the system made up from sodium chloride, sodium sulphate and water is one of four components, not three, should puzzle no one after reading this book.

One-component systems are dealt with in less than 40 pages, but with no lack of thoroughness. Polymers, glasses and infusible substances are all considered. It is impossible not to share Prof. Zernike's enthusiasm as he suggests new experiments for testing some moot point in the theory. It will come as a shock to many physical chemists to learn that as long ago as 1901 a case of superheating above the melting point of a crystalline solid was reported.

It is by the treatment of the binary systems, however, that the merit of a treatise on phase equilibria can best be judged. Since such systems can be described in terms of pressure, temperature and one composition variable, they are eminently suitable for pictorial representation on paper in all their aspects, either as pressure-temperature, temperature-composition or pressure-composition diagrams. Every chemist can draw the simple diagram showing the eutectic in a system composed of a salt in aqueous solution. The humps for the intermediate hydrates can probably be put in as well. Liquid-vapour equilibrium diagrams showing high and low boiling azeotropes are also part of the industrial chemist's repertoire. But how many of them can draw the diagrams showing equilibrium between solid, liquid *and* vapour phases together; especially if the components are only partially miscible in the liquid phase or completely miscible in the solid phase? What do temperature-composition and pressure-composition diagrams look like in the region of the critical points of the components? It is particularly pleasing to observe that the recent work on the nitrogen-ammonia system at high pressures, which has been reported as exhibiting two immiscible gas phases, is shown by Prof. Zernike to be entirely accounted for by classical theory, in that it is simply a system showing immiscible liquid phases at a temperature above the critical point of one of the components.

Prof. Zernike describes the systems which have been experimentally investigated, but points out that all the theoretically possible cases are by no means exhausted in his book. Having been shown the way, the astute reader is left to work out and draw new combinations for himself; certainly the quickest and best method of becoming an expert in the subject.

Ternary systems are not as difficult to deal with as might be at first imagined because no new parameter is involved; only a second composition variable. Prof. Zernike's treatment of ternary systems is just as thorough as that of the binary systems. His descriptions of the 'salting out' process and of systems of reciprocal salt pairs are masterly. In the case of multicomponent systems the chief interest lies in the graphical dodges which can be used to depict these systems, in part if not in entirety, on paper.

In his text Prof. Zernike has included 64 problems to tax the imagination and understanding of the reader. The answers are given at the back, and they should be tackled by every serious student. The book is very well produced, and the numerous diagrams are beautifully clear. Here and there a "bij" and a "probleem" have escaped the proof reader to remind us that this book is published in the Netherlands. Prof. Zernike's meaning is always clear although his English is occasionally unorthodox. These are not criticisms of the work; they add to the delight of reading it.

This book should be owned by every library and every serious student of the phase rule. It can be put alongside Roozeboom; no further praise is necessary.

PROPERTIES OF SYNTHETIC PIEZOELECTRIC CRYSTALS

Piezoelectricity

(General Post Office: Selected Engineering Reports.) Pp. x+369. (London: H.M. Stationery Office, 1957.) 75*s*. net.

As stated in the foreword, this volume is the first of its kind which makes available to the general public the results of engineering reports of the English General Post Office. This report by the staff of the Materials Division of the Research Branch is in the field of synthetic piezoelectric crystals. Dr. R. Bechmann (now at the U.S. Army Signal Corps Engineering Laboratory, Fort Monmouth, New Jersey) was responsible for the theoretical investigations and indicated suitable fields for experimentation. A. C. Lynch, and later P. L. Parsons, were responsible for the physical measurements. Dr. R. Taylor supervised the crystal-growing experiments. The preparation of the reports for publication was undertaken by Dr. R. Taylor and Mrs. S. Ayers.

The book starts out with a general description of the fundamental properties of piezoelectric crystals. The notation for the fundamental quantities, and for rotated cuts, follows that standardized by the Piezoelectric Committee of the Institute of Radio Engineers (United States). A chapter on the use of tensor transformation in calculating the properties of rotated cuts was written by Bechmann. Since all the properties of the crystal are measured by means of the resonant and anti-resonant frequencies of fundamental modes, a complete discussion of modes of motion is given by Bechmann and Ayers. A feature of this discussion is the use of contour modes for measurements. However, little mention is made of the very extensive thickness mode solutions obtained recently by Prof. R. D. Mindlin and his associates at Columbia University.

These studies are preliminary to the determination of crystal constants by resonant frequency and capacitance measurements. A chapter by Lynch and Parsons discusses automatic methods for tracing out such resonances. The coupling factor is determined by the difference in capacitance above and below the resonant frequency.

Next follow chapters on methods for growing water-soluble crystals, for measuring their orientations by X-rays and for cutting them with wet string saws. The crystals studied seem to be nearly identical with those studied at Bell Laboratories as substitutes for quartz in filter plates and for underwater-sound transducers. The particular crystals studied are ammonium dihydrogen phosphate, sodium chlorate and sodium bromate, ethylenediamine tartrate, lithium sulphate monohydrate and di-potassium tartrate. A rather complete study has been made of the tartrates, but no new crystals are produced. Very complete determinations have been made for the elastic, piezoelectric and dielectric constants of these crystals, which will probably remain the most authoritative determinations of these properties.

The present reviewer misses a chapter giving a survey of probable uses for such crystals. In the United States, the only water-soluble crystal which survived competition with natural and synthetic quartz is ammonium dihydrogen phosphate, which is still used in underwater sound equipment. This may not be true in Britain. In any event, the series of reports can be recommended as giving a very broad background in piezoelectric crystal investigations and as containing the most recent set of elastic, piezoelectric and dielectric constants for piezoelectric crystals. The general idea of making available for wider circulation a series of engineering reports of one organization is also a commendable one and should be extended further.

Warren P. Mason

HÆMOLYTIC DISEASE OF THE NEW-BORN

Comparative Aspects of Hæmolytic Disease of the Newborn

By G. Fulton Roberts. Pp. 199. (London: William Heinemann (Medical Books), Ltd., 1957.) 17*s*. 6*d*. net.

This account of hæmolytic disease of the newborn in man and animals is divided into nine chapters. The first, which deals with the history of the human disease, will probably be of limited appeal, but it serves a very useful purpose in giving proper credit to earlier workers in what is often assumed to be a modern preserve. Chapters 2 and 3 deal with hæmolytic anæmia and the problem of kernicterus, respectively. The latter chapter clearly suffers from the lack of knowledge on neonatal jaundice and the metabolism of the bile pigments, but the author comes through this ordeal well and is on firmer ground when discussing serological considerations in Chapter 4, which is stimulating and very much to the point.

At this stage, Dr. Roberts leaves the human infant and discusses, in two chapters, the disease as it is seen in the horse and the pig, and then, in Chapter 7, work on the experimental production of the condition. His grasp of the veterinary aspects of hæmolytic disease is sure and there is no lack of balance between human and veterinary medicine throughout the book. Chapter 8 is devoted to comparative pathology, and here the author best exhibits his gift for bringing together and assessing widely scattered data. A final chapter on treatment is brief but adequate for a book of this type.

In an age of increasing specialization, it is a pleasure to find an author who can see a disease as a whole. But Dr. Roberts does more than this in venturing along the many scientific paths that radiate from the clinical case. The book is written clearly and with great economy of words, and although the author describes it as a short account of present-day views it is, in fact, a comprehensive review with more than five hundred references.

PRACTICAL MODERN MICROSCOPY

Traité de Microscopie

Instruments et Techniques. Par A. Policard, M. Bessis et M. Locquin. Pp. vi+608. (Paris: Masson et Cie., 1957.) Broché, 4,500 francs; Cartonnétoile, 5,200 francs.

THIS book is concerned with the use of modern microscopes in biology. It contains much information that would be valuable to all users of microscopes, but it is especially well suited to the needs of pathologists, histologists and cytologists. The attempt to cover the requirements of these three groups in a single volume is becoming increasingly difficult, for new instruments and techniques are being invented one after another in almost bewildering profusion. The authors make a bold attempt to deal with the whole subject, from direct microscopy with the light microscope through phase-contrast and interference to electron-microscopy. The book is logically arranged and can be used as a work of reference as well as a text for systematic study. It can be strongly recommended. There is probably no other single volume that contains so much useful, up-to-date information on the subject. It is adapted throughout to the needs of the practical man, anxious to get the best results from his instruments by the use of rational techniques but not interested in the niceties of physical and chemical explanations.

In writing such a book as this, it is difficult to know how much physical and chemical explanation to include. Some of the theoretical sections are not satisfactory. A considerable amount of space is devoted to the theory of phase-contrast. It would not seem that the authors have had much experience in explaining the optical principles involved to intelligent persons ignorant of the subject. The treatment is neither well adapted to the needs of the beginner nor helpful to the initiated. It is possible to explain phase-contrast in a much more straightforward way, without any sacrifice of accuracy. The remarks on the theory of fixation and dyeing also leave a good deal to be desired. Indeed, it seems questionable whether the short sections on these subjects were worth including in the book. One might get the impression from the general remarks on pp. 289–290 that almost nothing is known about the chemistry of dyeing. In fact, of course, there is an immense wealth of knowledge, gained by the researches of Ehrlich, Fischer, Mann, von Möllendorff, Seki, Lison, Singer, and many others.

The balance of the book is on the whole good, though there may be a few subjects to which an unnecessary amount of space is devoted (secondary fluorescence, for example, and the shadowing of objects for light microscopy). Insufficient information is given on certain other subjects. It would not be possible to use collodion successfully as an embedding medium without more detailed instructions than are given here. Not nearly enough space is devoted to vital coloration. This important branch of microtechnique has unfortunately been pushed into the background by the invention of phase-contrast. Two objects that look identical by phase-contrast may react very differently to vital dyes, and a pointer may thus be given to differences of chemical composition. The techniques of vital colouring are not very easy to learn, and the account given in this book is inadequate.

The book contains a few mistakes in matters of fact. For example, neutral red is said to be a neutral dye, and the cochineal insect is described as a beetle; there is no mention of the use of tannin in the instructions for carrying out del Río-Hortega's tannin–silver method. There are some queer words in the list of English equivalents of French technical terms (falx image, gelatinous glycerin (for glycerine-jelly), kristall, microscop, prisma, etc.).

A defect of the book is the casual way in which the illustrations are introduced. Many of them are not referred to in the text, and one might suppose that they were chosen after the book had been written. The legends do not suffice in all cases to make the meaning clear.

The merits of this book greatly outweigh the minor defects that have been mentioned. It is clear, logical, modern, comprehensive, and eminently useful.

JOHN R. BAKER

H. K. MOOKERJEE MEMORIAL VOLUME

H. K. Mookerjee Memorial Volume of the Proceedings of the Zoological Society, Calcutta

Edited by J. L. Bhaduri, B. Biswas and S. P. Ray-Chaudhuri. Pp. ix+396+21 plates. (Calcutta: The Zoological Society, 1957.) Rs. 30; 50*s*.

PROF. MOOKERJEE had a distinguished career, both in Great Britain and in India, where he was the first occupant of the Sir Nil Ratan Sircar professorship of zoology at Calcutta. His influence on the development of Indian zoology is outstanding. When he was a student, teaching in zoology was intended for medical students and there was no special course of study in zoology followed in Bengal. The fact that thirteen contributions of the present issue have been written by Indian zoologists is ample evidence of his achievement in fostering the study of zoology in India.

In this memorial volume, thirty-two contributions are collected dealing with almost all aspects of zoology. They range from an article on "Sex Determination in Metazoa" by J. B. S. Haldane to an essay on "The Growth of Knowledge of Animals in Palestine from Paleolithic Times" by F. S. Bodenheimer. There are notes on mammals collected during a Himalayan Expedition by Biswamoy Biswas and H. Khajuria, and a study of the chromosome numbers in human cervical cancer by G. K. Manna.

Of the thirty-two papers, four deal with sex determination and genetics; four with cytogenetics; four with experimental biology; four with descriptive embryology; ten with evolution and systematics; and the remaining ones with entomology and protozoology, except for a contribution on palæozoology. It is obviously impossible to review in a brief space any of the contents of this book adequately, but it is perhaps worth while pointing out that of the non-Indian contributions, eight come from the United States, seven from the United Kingdom, one from the U.S.S.R., two from Australia and one from Israel, thus again bearing testimony to Prof. Mookerjee's influence on the development of zoology, not only in his own country but also abroad.

Indeed, the collection of papers on so many unrelated subjects, which at first sight appears somewhat haphazard, may be taken as a tribute to the width of Prof. Mookerjee's interests. A. GLUCKSMANN

Bulletin of the Institute of Nuclear Sciences 'Boris Kidrich'

Vol. 7. Pp. 166. (Belgrade: Institute of Nuclear Sciences 'Boris Kidrich', 1957.)

THIS volume contains papers in English, French and German, describing work by members of the Institute. The work is mainly in chemistry, including radio-chemistry, but there are also papers in nuclear physics and electronics.

My chief qualification for this brief review is that I spent a week in the summer of 1956 at the Institute, which is about ten miles east of Belgrade, at a place called Vinća. It is a 'little Harwell', equipped with canteens, houses, etc., as well as laboratories. The main equipment is to be an experimental reactor (with a power of 1 megawatt or more) which was being engineered in the U.S.S.R. The building work was half complete in 1956, but I have not heard that the reactor is working yet.

The Institute is therefore planned to centre on the physics and chemistry of nuclear reactors. But there are groups, as at Harwell and Saclay, working on nuclear physics research, instrumentation, etc. The atmosphere is very enthusiastic, and there are a number of able scientists there, many of whom have studied abroad, mostly in the Western countries but some in the U.S.S.R. The Institute is, of course, entirely Government supported and there are no formal ties with the University of Belgrade, though some of the staff also lecture there. The Government has evidently realized that it must start by building up research work, and my impression was that they have made a very good beginning. The British Council is interested in the Institute and in particular in arranging the exchange of publications with research departments in Britain.

H. W. B. SKINNER

The Flora of Wiltshire

By Donald Grose. Pp. iv + 824. (Devizes: Wiltshire Archæological and Natural History Society, 1957. Copies obtainable from The Museum, 41 Long Street.) 42*s*.

THIS flora is presented to a large extent in the format which has become traditional for such works in Britain. These publications are the product of much industry, stimulated largely by local pride and enthusiasm, but to botanists accustomed to dealing with the systematic problems on a world scale, county floras such as this seem proportionately to have scant scientific value. It is true that in the "Flora of Wiltshire" some ecology is included in the section dealing with the vegetation of the county, in the form of lists of species forming associations typical of selected habitats. In a county which is mainly agricultural and pastoral, with little elevation above 600 ft., and dominated by the chalk formations of Salisbury Plain and the Marlborough Downs, there is a surprising number of species represented. In all, some 1,406 flowering plants, ferns and charophytes are listed, of which just over 900 are deemed to be native to the county. No descriptions are given, and, as is usual in this typically British production, a very extensive knowledge is assumed of the British flora.

The book is really in the nature of a detailed catalogue and it is a pity that, in the fashion of the Druce era, there is such a proliferation of names of subspecific rank to which botanists will have difficulty in referring plants.

Check-List of North American Birds

Prepared by a Committee of the American Ornithologists Union. Fifth edition. Pp. xiii+691. (Ithaca, N.Y.: American Ornithologists Union, 1957.) n.p.

THIS big volume is a result of many years work (1939–57) of a committee of eleven eminent American ornithologists with Dr. Alexander Wetmore as chairman. The fourth edition of 1931 covered 1,420 species and subspecies, and in the present volume this number has grown to 1686. A hypothetical list including 41 species is also added. The area covered is North America north of Mexico, Greenland, Bermuda and Baja California. The distribution of each species or subspecies is treated with great care and detail, and especially in regard to some rarer species the amount of evidence and the manner of presentation deserve the highest commendation. The title of the book does not sufficiently indicate its contents, since it is much more than a simple check-list normally is. This long-awaited, excellent work is invaluable for everyone interested in the distribution of birds in general and especially of those of North America. Serious ornithologists will find it an indispensable source of information. It is very desirable that a similar check-list of European birds should be prepared as a counterpart of this American work, and the forthcoming twelfth International Ornithological Congress to be held at Helsinki in June offers a good opportunity to discuss the problem. The international compilation of such a monumental work seems not impossible and would certainly be a very valuable undertaking because no modern check-list of the birds of Europe as a whole exists at present.

W. RYDZEWSKI

Determinism and Indeterminism in Modern Physics

Historical and Systematic Studies of the Problem of Causality. By Ernst Cassirer. Translated by O. Theodor Benfey. Pp. xxiv+227. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1956.) 40*s*. net.

IN the halcyon days of the 1920's, most of the essentials of modern physics had been achieved. It is not surprising, therefore, that this distinguished book, written originally in German, but published in Sweden, should contain a large part of the epistemology necessary for the basic understanding of almost any system of natural philosophy. But it was intended to supply (in 1936) a final chapter on the causality problem, a project destined to failure, on account of the author's death. Luckily, Prof. Margenau, a close associate of the late Prof. Cassirer, has been able to contribute a very impressive preface on the most important developments in this field. It does two things: it brings out the contrast between 'causality' and 'determinism'—as Cassirer conceived them—and current interpretations, and it discusses recent advances.

Where the author himself is strongest is in his insistence upon the intimate connexion (almost amounting to fusion at times) between physics and the theory of knowledge. He takes account of the whole cycle, from the most mechanistic beginnings to the present-day sub-quantum determinism of David Bohm. In this way, the build-up of thought is seen to be continuous through the periods of matrix-calculus and wave-mechanics, and much of the dual character of Nature is made more comprehensible. The translation into English is excellent.

F. I. G. RAWLINS

NON-FLOWERING STRAINS OF HERBAGE GRASSES

By Prof. M. L. PETERSON*, Dr. J. P. COOPER and P. B. VOSE

University of California, Department of Agronomy, Davis, California, and
Welsh Plant Breeding Station, University College
of Wales, Aberystwyth

THE results of more than thirty years of grass breeding, together with the insight that has been gained into the physiology of flowering, now make it feasible to examine the possibility of producing 'non-flowering' strains of herbage grasses. These strains would remain permanently vegetative within the regions of their agronomic adaptation.

It has been realised since the early work of Fagan and Jones[1] and Woodman *et al.*[2] that the leaves of herbage grasses are lower in fibre, higher in protein content, and more digestible than the stems, and hence of greater nutritive value. For these reasons, plant breeders have deliberately selected leafy strains with a high proportion of vegetative to fertile tillers at flowering time. In spite of the lower proportion of heads, seed production of these leafy strains has proved quite practicable. The development of strains of grasses which remain permanently vegetative seems possible by continued selection in this direction[3].

Most herbage strains show marked seasonal productivity, characterized by a steady rise in production during the spring and early summer, and reaching a peak with the emergence of the inflorescences. Flowering and seed formation are followed by a depression in yield, which is succeeded by a secondary period of aftermath growth reaching a peak in the early autumn. This midsummer depression of yield has often been attributed to water shortage, but Hunt[4] has recently emphasized the seasonal growth-cycle and the seriousness of the summer gap under Ayrshire conditions, with a relatively high summer rainfall. Non-flowering strains should not exhibit such periodicity of growth, since their seasonal production would be determined by environmental factors, such as rainfall and temperature, rather than by the sequence of the reproductive cycle. They should also maintain a higher protein and lower fibre content than flowering strains.

The efficient utilization of incoming radiation for photosynthesis depends on the maintenance of a high leaf area index in the crop[5]. Langer[6] has found that *S*.48 timothy attains its maximum leaf area at about the time of ear emergence, this being followed by a period of rapid decrease during flowering, and then by a smaller rise in early autumn. In a non-flowering strain, the leaf area should remain at a high level during midsummer when both the incoming radiation and the net assimilation rate are at a maximum.

The absence of elongated flowering shoots may also make it easier to maintain a balanced grass-clover sward with a relatively constant proportion of grass to clover. It is during the stem-elongation stage of the grass that competition for light is most liable to depress the clover content of the sward[7].

The management of non-flowering strains could prove easier than that of normal herbage. Many farmers refuse to grow cocksfoot, *Dactylis glomerata*, because of the difficulty of retaining it in a palatable condition, and avoiding the 'tussocky' growth that easily arises under lenient cutting or grazing. Pastures of ryegrass, *Lolium perenne*, frequently become very stemmy after midsummer, and good management requires that they should then be topped over with the mower. The importance of keeping herbage short and leafy is emphasized in the gang-mowing technique of Merricks[8], and a non-flowering strain could supply such short, leafy herbage. A non-flowering strain of ryegrass would also be an obvious choice for playing fields.

There are, however, certain difficulties attached to the use of non-flowering strains of grasses, the most obvious being their economic propagation. Although vegetative propagation is practicable for special purposes, such as lawns and sports grounds, adequate seed supplies are essential for use on a farm scale. A study of the physiology of inflorescence development in the herbage grasses suggests several ways of overcoming difficulties in propagation. A strain which fails to flower in one environment may produce heads freely in another, so it should be possible to choose seed-growing areas of appropriate climate and latitude.

Absence of heading may be associated with low vigour or with late spring growth, but the main advantage of such strains would lie in their steady mid-season production. Sylvén[9] observed that a strain of meadow fescue, *Festuca pratensis*, from north Sweden which failed to flower in the south because of inadequate photoperiod also showed poor vegetative vigour. On the other hand, spaced plants of perennial ryegrass and cocksfoot, which remained vegetative when grown in California, were quite vigorous in relation to flowering plants. In the ryegrasses, late heading and late spring growth are not invariably correlated. The late-flowering pasture strains, *S*.23 and *S*.101, are known to be later in spring growth than the early-flowering strains. However, Italian ryegrass is later in heading date, but is earlier in spring growth than the early-flowering perennial ryegrasses.

Most grasses of temperate regions require long photoperiods for floral initiation and stem elongation, although the time from ear initiation to ear emergence is modified by spring temperature[10,11]. Species of economic value the flowering behaviour of which has been studied include *Bromus inermis*[12–14], *Cynosurus cristatus*[15], *Dactylis glomerata*[12,13,15,16], *Lolium perenne*[11,15,17], *Phleum pratense*[12,13], and *Poa pratensis*[12,13,18]. Both species and strains vary in their exact photoperiodic responses, earliness or lateness of heading depending on the critical photoperiod. In *Lolium perenne*, for example, the early-flowering strains, Irish, Ayrshire and *S*.24, will initiate heads in a photoperiod of 11–12 hr., while the later-flowering *S*.23 and *S*.101 require 13–14 hr. or more for spikelet initiation[11,17]. Similarly, in *Phleum pratense* the early-flowering American strain Marietta, from Ohio,

---

* Senior Fulbright Scholar; Professor of Agronomy, Davis, California.

Table 2. Response to Selection for Early and Late Flowering in Kent Perennial Ryegrass

Original population Mean	(Extreme)	First generation Mean	Second generation Mean	Third generation Mean	(Extreme)	Direction of selection
22.8 May	(3 May)	5.9 May	27.2 April	28.2 April	(16 April)	Early–early
	(5 June)	30.4 May	3.6 June	8.7 June	(21 June)	Late–late

All figures refer to date of ear emergence in 1957. Each mean based on fifty seedlings; S.E. of mean = 1·06

will begin to produce heads in a 12-hr. photoperiod, while the later-flowering Canadian strain Huron requires 13½ hr. or more[12]. The photoperiodic requirements of a strain are closely related to its latitude of origin, and the transfer of material to different latitudes often results in altered flowering behaviour. Allard and Evans[12], for example, find that strains of *Phleum nodosum* from north Europe (50–60° N.) fail to head or head very sparsely in natural photoperiods at Washington, D.C. (39° N.), but will flower freely under supplementary illumination. In Sweden, Sylvén[9] gives examples of plants of *Festuca pratensis* from north Sweden (66° N.) which fail to head when brought down to the south (56° N.).

The flowering behaviour of *S*.23 perennial ryegrass has recently been compared at Aberystwyth (52° N.) and Davis, California (38° N.). Seed of this strain when grown at Davis gave rise in 1955 to a number of non-heading plants. These were induced to flower the following year and interpollinated in a group, the seeds from each mother plant being harvested separately. The nineteen progeny lines and the original *S*.23 were grown outdoors at Aberystwyth and at Davis, and the percentage of plants heading and the median heading date were recorded for all lots in summer 1957 (Table 1). The results indicate that while at Aberystwyth all plants headed except for two in line 7, in California most lines showed a proportion of non-heading plants, this being as high as 40 per cent in line 7. The two plants which failed to head under natural photoperiods at Aberystwyth produced heads when transferred to continuous light in the glasshouse. At both Davis and Aberystwyth nearly all the progeny lines were later than the original *S*.23, and there is a significant correlation (+0·828) between the median heading dates for the two stations. Furthermore, those lines which were later heading at Aberystwyth showed a higher proportion of non-heading plants at Davis, suggesting that in both cases a high photoperiod requirement is involved.

These studies suggest that it is possible to select plants which fail to flower in a particular latitude because photoperiodic requirements are not satisfied. It is not yet known whether such plants will fail to flower in succeeding years. There is the possibility that such plants may be carried only part way towards floral induction in the first season, and failing to head will proceed from that point on in the next season or seasons until heading ultimately occurs. The answer to this problem awaits further research.

Table 1. Heading Behaviour of *S*.23 Perennial Ryegrass and Derived Progeny Lines at Davis, California (38° N.), and at Aberystwyth, Wales (52° N.)

California material, sown October 15, 1956, planted outdoors November 26, 1956. Aberystwyth material, sown November 25, 1956, given 80 days cold treatment at 0–5° C., planted outdoors February 23, 1957

There have been few detailed investigations of the inheritance of flowering behaviour in the herbage grasses, but in *Lolium*, Cooper[19] finds the difference between the early-flowering group (Wimmera and Irish) and the late-flowering *S*.23 perennial ryegrass to be polygenically controlled, with no evidence of one or a few main gene differences. In these outbreeding strains, most plants are highly heterozygous for genes controlling flowering date, and the genetic variance of progenies from selfing or crossing individual plants is of the same order as that of the whole population. As a result, much potential genetic variation is stored in the population, making possible considerable response to selection. In Kent perennial ryegrass, three generations of selection were made for early and late flowering, beginning with four early and four late-heading plants. As shown in Table 2, selection for earliness advanced the mean heading date 16·9, 25·6 and 24·6 days, respectively, in each of three generations of selection. Selection for lateness retarded mean heading dates 7·6, 11·8 and 16·9 days, respectively, for three generations. A divergence in mean heading dates of 41·5 days and a divergence between extreme plants of 66 days was obtained in the third generation[20]. This difference of sixty-six days corresponds to a difference in photoperiod of about 3½ hr. at Aberystwyth (52° N.).

In addition to their long-day requirement for floral initiation and subsequent development, many temperate perennial grasses possess a 'winter' requirement for short day and/or low temperature before floral induction is possible, little or no heading occurring after a late spring sowing. Such a 'winter' requirement has been reported for *Bromus inermis*[14], *Cynosurus cristatus*[15], *Dactylis glomerata*[16], *Lolium perenne*[15,21], and *Poa pratensis*[18], but does not occur in *Phleum pratense*[22,23]. In *Lolium*, both low temperature and short days have an inductive effect, either alone or when combined. Cold induction can be given to the imbibed seed, to the young seedling, or to the mature plant, but for short-day induction, some leaf tissue must be expanded. In *Poa pratensis*, Peterson and Loomis[18] find that both low temperature and short days are necessary for floral induction, while in *Dactylis glomerata*, Gardner and Loomis[16] report that short days must accompany or precede the cold treatment.

Strain or ecotype differences in 'winter' requirement also occur. In *Lolium*, there is a close correlation between the degree of 'winter' requirement and the annual, biennial or perennial habit[20,21]. The summer-annual Westernwolths ryegrass possesses no requirement for either low temperature or short-day, while the winter-annuals, such as Wimmera ryegrass, show a quantitative response, heading being accelerated by either cold or short-day. In the biennial Italian ryegrass, some plants fail to head without exposure to winter conditions, the proportion of non-heading plants varying with the climatic origin of the material. In perennial ryegrass nearly all plants have an obligatory requirement for cold or short day or both, this being greatest in the persistent pasture strains and least in the shorter-lived 'commercial' types. Plants of Irish, *S*.24, *S*.23 and *S*.101 perennial ryegrass have been kept vegetative for more than two years under continuous light in a warm glasshouse.

As with the requirements for long photoperiods, the response to low-temperature induction in *Lolium* is polygenically controlled[19], no main gene differences having been detected in crosses between the annuals, Wimmera and Westernwolths ryegrass, and perennial ryegrass. Furthermore, considerable genetic variation is carried in the heterozygous state within individual plants, and gradually becomes available for selection.

In the temperate herbage grasses, therefore, at least two developmental mechanisms exist whereby the timing of inflorescence development can be controlled; a 'winter' requirement for short-day and/or low temperature before floral induction is possible, and also a requirement for long photoperiods for floral initiation and subsequent development. Considerable genetic variation in all these responses has been shown to exist within species, its distribution being related to the climatic or agronomic origin of the material. It should therefore be possible to select, in a particular region, plants which remain vegetative indefinitely, because their requirements for either 'winter' exposure or long summer photoperiods are not satisfied under local conditions. They may then be grown for seed production in districts or under artificial conditions favourable for reproductive development.

A fundamental problem in the production of a non-flowering strain is to decide whether to concentrate on the photoperiodic response or the 'winter' requirement, as the factor limiting inflorescence development. In this connexion, the seasonal regularity of the limiting factor is important. Winter temperatures in one locality vary considerably from year to year, and the response to winter conditions in one season may not be strictly reproducible in subsequent years. The effective temperature-range for cold induction is not known for most herbage grasses, nor do the usual meteorological records give an exact measure of the temperature experienced by the growing point of the grass plant. It is clear that the regional mapping of effective winter temperatures may be rather difficult. On the other hand, the seasonal distribution of photoperiod is regular from year to year, and being based only on latitude, can be calculated accurately for any locality. Apart from the modifying effects of temperature during inflorescence elongation, flowering performance in any one season may therefore serve as a guide to future behaviour. Response to photoperiod thus forms a more reliable basis for the production of non-flowering strains.

The next step is to obtain plants the critical photoperiod of which is above that of the longest summer day in the region where the strain is to be used. One obvious source is the collection of late-flowering material from higher latitudes. In the case of Davis, California (38° N.), this presents few difficulties. The longest summer photoperiod (as measured by civil twilight) is only about 16 hr. and the British pasture strain of perennial ryegrass, *S*.23, has already provided some non-flowering plants when grown in California. For Aberystwyth (52° N.), with a maximum summer photoperiod of about 18 hr., the problem is rather more difficult, since plants with a critical photoperiod above this figure are only likely to occur naturally in arctic or sub-arctic latitudes, thus restricting the initial choice of material. Plants with such high critical photoperiods do exist in arctic regions. Material of *Oxyria digyna* brought back from Jan Mayen Island (71° N.) by Wilson[24] remained vegetative under natural photoperiods at Reading (51° N.), but flowered freely when given continuous illumination.

Another source of non-flowering material lies in selection from within existing late-flowering strains. As already mentioned, outbreeding strains of *Lolium perenne* contain considerable potential genetic variation which is released in each generation by segregation and recombination, and thus becomes available for selection. For example, samples of Kent perennial ryegrass showed a mean date of ear emergence of May 23, 1957, at Aberystwyth, with extreme plants on May 3 and June 5, but three generations of selection for lateness of heading from this strain have produced plants in which heading is delayed until June 21, 1957 (Table 2). The later-flowering strain, *S*.23, might provide even more useful material for selection (see Table 1). One advantage of using existing strains is that they are already fairly well adapted for vigour and herbage production under local conditions.

There remains the possibility of using non-flowering mutants. These have been recorded from inbred progenies of Italian ryegrass at Aberystwyth[25]. Natural mutants occur infrequently, but induced mutants might be obtained by irradiation.

Whether the non-flowering plants are derived from collections from high latitudes, or by selection from within existing strains, they will provide only raw material for further breeding and selection. They may, for example, lack the ability to grow at low temperatures in the spring, a character which could then be introduced from Italian ryegrass.

Even when non-flowering plants of satisfactory performance have been obtained, the problem arises of seed supply on an economic basis. Obtaining seed from small lots of non-flowering plants, either for breeding purposes or for the production of foundation seed, offers no problem. Flowering may readily be induced by extension of the day-length using incandescent lamps of low wattage, the plants being kept outdoors or in an unheated greenhouse. In long-day plants, it is the length of the dark period which is important in preventing flowering, and reproductive development can be induced by a short break in the middle of the dark period. Artificial light, therefore, need only be used for a short time at midnight, and has in fact been employed for this purpose in the production of sugar beet seed in breeding nurseries in the United States.

For larger quantities of seed, artificial lighting is not practicable, and seed production would have to be carried out at higher latitudes, where the day-length is adequate for floral induction. In Britain, this would mean growing seed crops in the north of Scotland, preferably above latitude 58° N. A strain could probably be selected which would flower at that latitude, and yet remain vegetative in the south of England. The flowering and vegetative limits of such a strain would be an integral part of its description.

The farther north the strain is to be used for pasture, the more difficult it will be to produce a non-flowering strain, since there will be fewer areas suitable for seed production. To obtain a strain which would remain vegetative everywhere in Britain, for example, seed would have to be grown on a commercial scale at latitudes above 60° N., probably in Scandinavia.

Although the biochemical basis of the photoperiodic response is not yet fully understood, it seems probable that in the future it will be possible to induce flowering in unfavourable photoperiods by suitable chemical treatment, thereby removing the main difficulty of seed production in non-flowering strains.

In conclusion, it seems clear that the production of non-flowering strains is now technically possible, but their economic use in farming practice will depend largely on the cost of seed production. It is suggested that the development and testing of such non-flowering strains deserve serious consideration.

RADIOMETRIC AND GEOCHEMICAL SURVEY TECHNIQUES

At the Geophysical Discussion of the Royal Astronomical Society held on January 31, Sir William Pugh introduced four invited speakers. He referred to the importance of atomic energy to our national economy and added that, although we had recently heard of the possibilities of the controlled release of thermonuclear energy, the present reactor programme was based upon uranium as the main fuel element. In view of this, and of the increased demands for rarer metals of value to our expanding industries, he stated that it was particularly appropriate to discuss radiometric and geochemical methods of prospecting at this time.

Mr. S. H. U. Bowie, in opening the session, recalled that prior to the Second World War only two mines, namely, Shinkolobwe in the Belgian Congo and Eldorado in Arctic Canada, produced significant tonnages of uranium ore ; but, as a result of the intensive search during the past decade, more than 300 mines were now in production. Most of the discoveries had been made by the sound application of geological knowledge aided by instruments capable of detecting and measuring the gamma radiations from near-surface mineral occurrences. Both Geiger–Müller and scintillation counters are used in prospecting, and a variety of different instruments had been designed for specific purposes. The choice of a suitable instrument depends largely on the degree of reproducibility sought. If no allowances are made for terrain factors such as local topography, absorption of gamma photons by soil cover, or disequilibrium between uranium and its daughter elements due to weathering, a high statistical accuracy in the measurement of count-rate is unnecessary. Thus, a light-weight ratemeter, which averages the pulse-rate over a short period of time and has a count-rate of one or two pulses per second over flat-lying bedrock of a grade equivalent to 0·001 per cent equivalent U_3O_8, is adequate for preliminary prospecting purposes. More sensitive instruments are necessary for use by geologists in the detailed gridding of an area of anomalous radioactivity. In car-borne and airborne surveys, where the average radioactivity over intervals of traverse is recorded, scintillation counters of high sensitivity are necessary. For example, to obtain a count-rate of an accuracy of 10 per cent over 50-ft. intervals of traverse at a speed of 30 m.p.h., the count-rate of the instrument would have to be about 85 pulses per second over the same low-grade bedrock.

Airborne ratemeters designed by the Atomic Energy Research Establishment have single or triple thallium-activated sodium iodide crystals each $4\frac{5}{8}$ in. in diameter and 1 in. thick coupled optically to a photomultiplier tube. Flight altitude and lane widths are dependent on the geology of the terrain to be surveyed, but two general techniques have been evolved. In one, flying is undertaken at an altitude of 500 ft. and at lane-widths of a quarter of a mile ; in the other, the altitude is usually between 200 and 300 ft. and the lane-widths reduced accordingly.

Mr. Bowie concluded by saying that because of the ease with which uranium and thorium can be detected by geophysical means, geochemical techniques were not so important in the search for uranium as in the search for base metals. However, because of the high degree of mobility of the uranyl ion $(UO_2)^{2+}$ in solution, the detection of uranium in run-off water, particularly in river basins draining mountainous or forested country, was a valuable aid in the delineation of favourable areas.

Dr. J. S. Webb, who followed, said that geochemical methods of mineral exploration are based on the premise that diagnostic disturbances in the normal distribution pattern of chemical elements may exist in accessible material in the vicinity of concealed ore deposits. Such geochemical anomalies result from the natural dispersion of elements from the site of the parent deposit and are commonly sought by the systematic sampling and analysis of rock, soil, vegetation, stream water and stream alluvium.

Geochemical dispersion patterns are subdivided into two genetic categories, namely, *primary dispersions* formed in depth at the time of mineralization, and *secondary dispersions*, which are usually formed in the zone of weathering. Primary dispersion patterns may occur as regional variations in the trace element content of rocks and minerals associated with metallogenic provinces, aureoles of impregnation in the wall-rocks surrounding individual deposits, or 'leakage' dispersions of trace metals in the channel-ways followed by mineralizing solutions. In all cases, the primary dispersion is genetically related to the ore-forming processes. The interpretation of the geochemical anomalies in terms of the location of possible associated deposits is often difficult and is dependent on the understanding of the local geology. Secondary dispersions, on the other hand, are usually associated with the weathering cycle, and although the dispersion processes are complex, considerable progress has been made in the development and application of techniques having a proved practical value in prospecting. This is particularly true of geochemical soil surveys in areas of residual overburden, where the methods have been successfully used for detecting the presence of sub-outcropping deposits of copper, nickel, arsenic, gold, antimony, chromium, tin, tungsten, molybdenum and other metals.

At times, positive results have been obtained where copper, lead and zinc mineralizations have been concealed by transported glacial cover up to some tens of feet thick. Here, the metals have had the opportunity of migrating upwards into the overlying material by diffusion and other processes, including the growth of vegetation which has extracted the ore metals as part of its nutrient uptake. Although the systematic analysis of the plants themselves has been employed on occasions, it is normally found more practicable to sample the underlying soil wherein metal has accumulated over generations in the biogeochemical cycle. Geochemical soil and vegetation anomalies are usually restricted to the immediate vicinity of the parent mineral deposit, but abnormal concentrations of metal may sometimes be detected in the surface drainage system up to several miles downstream from mineralization. Where such geochemical dispersion does exist, the systematic sampling of stream water or alluvium may constitute a useful aid in the rapid mineral reconnaissance of comparatively large areas. Sampling and analysis of stream alluvium for metals extractable at normal temperatures have given particularly encouraging results in reconnaissance for copper and base metal deposits.

The practical application of geochemical methods has been made possible only by the development of extremely rapid, simple tests and there are now trace analytical techniques for a wide range of metals capable of being performed with adequate accuracy by semi-skilled personnel. For the most part, these tests are simplified versions of classical colorimetric and chromatographic methods, although spectrographic, fluorimetric and other procedures may be utilized for particular problems.

Current research is active and aimed at broadening the scope of existing methods, extending knowledge of dispersion processes, investigating the regional approach to comprehensive geochemical reconnaissance and developing appropriate analytical techniques. Progress in the application of geochemical techniques indicates that, when used in conjunction with geological, geophysical and other sources of information, they will play an increasingly greater part in modern mineral exploration.

Mr. J. E. T. Horne next spoke on the determination of the age of radioactive mineralization and the importance of this in the search for further deposits. Knowledge of the age relationships between a mineralization, its enclosing sediments, and any igneous activity in the area could give, in many instances, a clearer indication of where to look for further occurrences. Such information was also valuable in understanding the genesis of ores, particularly in deciding between epigenetic and syngenetic origins. An example of a detailed age study that had led to practical results was the work of the United States Geological Survey on the uranium mineralization of the Colorado Plateau. There, field evidence had suggested a mineralization penecontemporaneous with the Triassic and Jurassic sediments, but analysis of more than fifty samples pointed to a late Cretaceous or early Tertiary age. This conclusion assisted in guiding a most successful prospecting and drilling programme.

Mr. Horne outlined the principles of dating uranium and thorium minerals from the four ratios lead-206/uranium, lead-207/uranium, lead-208/thorium and lead-207/lead-206, and discussed some of the factors responsible for the frequent lack of agreement in the derived ages. Formerly, the fact that lead/lead ages are commonly higher than the lead/uranium ages was attributed to the loss by diffusion of radon generated in the uranium-238 series, but laboratory measurements had failed to substantiate such loss in most cases. Lead derived from uranium and thorium before the deposition of a radioactive mineral and incorporated in it at the time of formation would seriously affect the apparent ages, and there was good evidence that such original radiogenic lead is present in some ore deposits. In this case, not only did all the apparent ages differ from one another, but also they were all too high. A third major cause of discrepancy was the loss of lead, either recently by leaching or earlier by solid diffusion. It was interesting that leaching experiments on some materials had effected a differential loss of lead-208 with respect to the other lead isotopes, indicating a difference in the distribution of uranium and thorium in the mineral. Finally, age discrepancies might arise from the loss of uranium or thorium and it was imperative to minimize this effect by obtaining the freshest possible material.

Age determination was not simple, but neither should it be dismissed as thoroughly untrustworthy. Some deposits were much more difficult to date than others ; these latter required the analysis of a comprehensive set of carefully selected samples, supported by meticulous observations in the field and mineralogical laboratory. Processes postulated to account for discrepancies must be established beyond reasonable doubt by independent evidence.

The last of the four principal speakers, Dr. W. Bullerwell, approached radiometric methods in borehole logging by discussing geophysical logs in general. He indicated, with examples from a deep boring for coal, how such records assist where core-recovery is poor and how geophysical marker horizons can help correlation between adjacent uncored boreholes. He stressed the importance of obtaining physical data on the properties of rocks from measurements made *in situ*, as the information so obtained could be applied in interpreting surface geophysical surveys. The continuous nature of the records also facilitates sampling and the averaging or integration of physical properties over a column of strata.

Just as classical studies first concentrated on natural radioactivity and later turned to activation methods, so borehole measurements of natural gamma radiation were followed by neutron techniques. For natural radiation measurements, ionization chambers, Geiger counters and scintillation counters have been used. The latter have a shorter 'active length' and this gives improved discrimination of thin beds. A relatively recent development is the scintillation spectrometer, which is capable of differentiating between the various energy-levels of incoming gamma rays. Since different elements are associated with gamma rays of differing energies, it becomes possible, in some instances, to obtain an indication of the nature of the nuclides responsible for the radioactivity by studying the pulse height distribution.

In neutron methods a neutron source is lowered into the borehole, followed by a detector. Neutrons will be captured by nuclei of the atoms that make up the surrounding rock, and the gamma rays emitted during these reactions can be recorded on a gamma detector. Similarly, if a neutron detector is used the distribution of neutrons in the borehole can be studied. Neutron sources commonly used, for example, radium–beryllium, also emit gamma rays, and it is necessary to shield the detector from the source in both neutron–neutron and neutron–gamma methods. Compton scattering and natural activity of the formation add complications. In gamma–gamma logging, which combines a gamma source and gamma radiation detector, scattered radiation, however, provides information related to formation density. Neutrons lose most of their energy in collisions with hydrogen, and as this element is abundant in both water and oil, neutron logs are important for porosity studies in oil exploration. In mentioning the combination of a neutron source with a scintillation spectrometer as detector, Dr. Bullerwell said that this would seem to offer the possibility of obtaining geochemical data by a geophysical method. A miniature Van de Graaff particle accelerator, 3 in. in diameter, 47 in. long and generating 200,000 V., has been used to produce an intense beam of neutrons during borehole experiments in the United States.

Radiometric logging methods have been applied in widely differing fields. Applications to detailed studies of radioactive ore-deposits are usually quite direct and closely controlled by assayed samples. Quantitative comparisons between sedimentary formations in oil-wells or deep structural boreholes, however, are complicated by varying conditions of observations. Calibration of instruments provides little difficulty, but ancillary data must be recorded to permit adequate correction for variations in borehole-diameter, mud-density, cement collars and thickness of casing. In concluding, Dr. Bullerwell stressed that these methods provide basic geophysical information, and he expressed the hope that should the proposal to drill a deep borehole to explore the Mohorovičić discontinuity come to fruition, then the opportunity to obtain a comprehensive series of geophysical logs should not be overlooked.

The chairman closed the meeting after a short informal discussion in which several speakers took part.

S. H. U. Bowie

CLIMATE, VEGETATION AND LAND UTILIZATION IN THE HUMID TROPICS

At the Ninth Pacific Science Congress, which was held at Bangkok, Thailand, during November 18–December 9, two days were devoted to a symposium on climate, vegetation and land utilization in the humid tropics, in which some eleven speakers dealt with different aspects of these closely related subjects. In addition to papers read by their authors, a few papers were read on behalf of contributors who were not present, and some invited guests, including one of the present writers (P. W. R.), who did not prepare papers, were asked to contribute to the discussions. The convener was Dr. F. R. Fosberg (Pacific Vegetation Project, Washington, D.C.), and the symposium was organized, and its proceedings will be published, with the financial support of Unesco. As so often happens, the time allotted for general discussion proved insufficient; nevertheless, a valuable opportunity was provided for an exchange of ideas between workers in different disciplines which do not come often enough into contact.

At the outset there was the question of definition: What do we mean by the tropics in general and by the humid tropics in particular? Broadly, as Dr. Fosberg said in his opening remarks, the two belts of trade-winds blowing towards the equator and the shifting belt of calms or doldrums are of greatest importance in defining these regions. Dr. David I. Blumenstock (Hawaii), who contributed a paper on the characteristics and distribution of tropical climates, expanded this by reminding the Congress of the special significance of weather or circulation regions, such as the monsoon region and, perhaps surprisingly, the hurricane areas; he regarded the tropical climatic realm as best defined as the region within which the temperature of the coldest month in the lowlands averages at least 64·4° F. (18° C.), with the included upland and mountain areas. In this sense the lowland humid tropics are the frost-free areas of the world, where the unique features are in the illumination and radiation regimes rather than in that of insolation. Dr. Blumenstock considered that radiation is a more important factor than previously believed. In regard to temperature he emphasized the importance of extremes; in regard to moisture, the significance of dew and the variability of rain through the year.

Dr. C. G. G. J. van Steenis (Leyden) and Dr. Carl Troll (Bonn) dealt, respectively, with the lowland and the mountain vegetation of the tropics. In the course of a very comprehensive review of tropical-vegetation types, van Steenis took the discussion away from mathematically defined climatic types to vegetation types related to different phytoclimates. After briefly discussing plant life-forms and the use of individual plant species as climatic indicators, he proposed a system of ten 'fundamental' climatic types of tropical lowland vegetation. This was later criticized by Prof. P. W. Richards as consisting of a mixture of climatic, edaphic and seral types of very unequal importance in the tropics as a whole. Dr. Troll made out the case for six altitudinal zones of tropical mountain climates, again based chiefly on vegetation. He demonstrated the use of thermo-isopleth diagrams and stressed the importance of frost in determining the altitudinal zones in the tropics.

A trend away from the definition of tropical climatic types in terms solely of a mathematical interpretation of figures, and towards one based on their influence on vegetation and crops appeared in the contributions of Dr. F. Egler (Aton Forest, Connecticut) and Prof. P. Dansereau (Montreal); the former, in fact, stated the case for the geographer's approach (though he did not refer to it as such, but called it 'holism') in suggesting that climate, soil and vegetation must not be regarded, as they sometimes have been in the past, as mutually exclusive fields of study.

The sad death of Dr. R. L. Pendleton and the illness of Dr. D. L. Bramao left the preparation of a statement on tropical soils to Dr. R. Dudal (Food and Agriculture Organization). Although he described his paper as a hurriedly prepared draft and it was not available to the Congress until the symposium was over, his succinct oral presentation conveyed conviction that at last a logical classification of tropical soils was being worked out. Where tests had been made, in Java and Borneo, the ten types in the scheme proposed arrange themselves in a logical sequence related primarily to relief—slope and drainage. The principle that the soil types are related to a certain range of land-forms as well as to vegetation was in line with points made by Dr. Egler and later by Dr. Christian.

The whole symposium stressed the need for the survey or observational approach to many of the problems. The huge areas in tropical Australia, Papua and New Guinea surveyed from the air and mapped under his direction led Dr. C. S. Christian (Commonwealth Scientific and Industrial Research Organization) to ask how best the results may be utilized. He saw that the land must be considered as embracing all factors of importance to man's well-being. Specific areas identifiable by their 'major observable inherent features' (of topography, soil, vegetation and climate) are termed by Christian 'land units' grouped into 'land systems'. These are more or less equivalent, respectively, to the 'stows' and 'tracts' of J. F. Unstead, and because of the other uses of the word 'system' as applied to land, 'tracts' is perhaps a safer word to use.

The cartographic approach to the problems discussed in the symposium was dealt with particularly by Prof. Henri Gaussen (Toulouse), who exhibited a number of the vegetation maps of France and other countries produced by his laboratory. He suggested the publication of a series of maps of vegetation in the tropics on the scale of 1 : 1,000,000, the only scale on which base maps are generally available. Gaussen's scheme agrees essentially with that advocated by the Commission on World Land Use Survey of the International Geographical Union in mapping the vegetation actually present (that is, without making any theoretical assumptions about 'climaxes', etc.), but whereas Gaussen uses only eight types of vegetation—four types of forest, savanna, desert, shores and cultivation—the World Survey considered it possible to go further in separating categories of land-cover; it also thought that the interpretation of the pattern found should be made in explanatory memoirs, while Gaussen believes it possible to indicate ecological conditions by colours on the map itself. The case for these two alternative approaches has been argued before on many occasions. The World Land Use Survey wished to make the maps as objective as possible; the facts can be interpreted in more than one way and if, as Gaussen proposes, the ecological factors believed to be responsible are shown on the map itself, a subjective judgment is necessarily introduced. Given the validity of the underlying assumptions, however, the magnificent quality and value of the Gaussen maps will be generally acknowledged.

If the first day of the symposium may be said to have dealt with the fundamental features of man's environment, the contributors on the second day dealt mainly with the effects, direct and indirect, on these features of man himself. The opening speaker, Dr. E. Aubert de la Rüe (Paris), gave a broad review of the rapid disappearance of the natural plant cover in all parts of the tropics, which in the future may be seen only if national parks and nature reserves are established. Dr. Dioscoro S. Rabor (Silliman University, Philippines) in a communicated paper dealing with wild life in the Philippines made the further point that wild life (that is, mammals and birds) depends on the natural vegetation, and as long as that is conserved it, too, is protected.

Dr. Carl Sauer (University of California) in a communicated paper on "Man in the Ecology of Tropical America" accepted as proved (perhaps rather surprisingly) the view that there was formerly a much larger population in the American tropics and argued for the presence of numerous agricultural tribes even in the forests of Amazonia. Both he and Dr. Ooi Jin-Bee (University of Malaya), who followed with a paper on the distribution of present-day man in the tropics in a historical and ecological perspective, noted the comparatively simple relationship between human distribution and favourable environmental conditions (such as the wet lowlands suitable for rice in south-east Asia) in the past and the changes consequent on the development of exploitable resources. Dr. Sauer held that in the American tropics European livestock were able to range over the former fields of a decimated sedentary population. Whether this was so or not, it is generally agreed that much savanna formerly regarded as climax vegetation does not correlate well with either climate or soil and can only be explained by the destruction of tree seedlings during man's annual burning of grass. Tropical grasses are only palatable to stock when young and tender, hence the need to burn off the old tough stems and encourage new growth. A paper from Dr. R. O. Whyte (Food and Agriculture Organization) here reminded the symposium that scientific management of tropical grasslands has scarcely begun, and that a first step in any area is to try to understand the relationship between grassland and the climatic climax vegetation when the biotic factors of grazing and burning are eliminated.

A major current problem in the tropics is undoubtedly the integration of agriculture and forestry.

A paper from Mr. Colin Marshall (Malaya) emphasized some fundamental truths which are certainly not appreciated by most policy makers in tropical countries at the present day. The increase of population with the spread of Western medical, sanitary and economic systems in tropical countries makes scientific land-use planning and its acceptance by governments and peoples absolutely essential. It is perhaps because scientific forestry—the intelligent management of forested land on a sustained yield basis—has been imposed on the peoples of tropical Asia from outside that in their new-found independence there is an undoubted tendency to regard forest reserves not as an attempt to conserve a valuable resource or to control soil erosion and make good use of land unsuitable for other economic use, but as a restriction on the liberty of the people. The creation of useless wastes in many parts of the world is due to the mistaken concept that forest is simply an impediment to be destroyed in order to free land for grazing and cultivation. Nothing is more important than that forests should be maintained to perform their many functions in a balanced land economy; only land which can be used more effectively in that way should be turned over to cultivation.

This leads on to the question of shifting cultivation, which was dealt with by Dr. Karl Pelzer (Yale University), who, however, wished to replace the term 'shifting cultivation' by 'swidden farming'. It is not wholly bad, he said, as is sometimes maintained. Where it is a deliberate agricultural technique (as with 'bush fallow' in parts of Africa) the cultivator knows the value of rotating his patches of cultivation to maintain soil fertility and can be regarded as conservation-minded. Yet the forester recognizes the extravagance of a system in terms of land, which prevents the regeneration of natural forest or economic timber while maintaining the land almost completely idle for perhaps a dozen years out of fourteen. In exceptional cases, useful quick-growing trees such as *Casuarina* are deliberately planted in the fallow period, but normally there can be little doubt that the substitution of some other system or systems is vital and urgent. But what other systems? Almost certainly not the permanent dry-field cultivation of annual plants practised in mid-latitudes. The right use of many upland tropical areas is in perennial, especially tree, crops; while in many lowlands wet rice fields are not only a productive form of cultivation but ensure a well-guarded soil. In other words, agricultural developments must be integrated with physical conditions.

Prof. Dudley Stamp, in a paper on "Land Use in the Humid Tropics: Living Space and Recreation", directed attention to uses of land other than for food production; man can indeed not live by bread alone. The need of land for housing, industry, defence and recreation competes with the need of land for agriculture. In crowded countries where there is difficulty in deciding between alternative uses of land in the national interest, three principles may be applied—that of optimum use, that of multiple use, and that of the elimination of waste land.

In the concluding paper of the symposium the chairman and convener, Dr. F. R. Fosberg (Washington), considered man from an ecologist's point of view. Hitherto, he pointed out, man has behaved as a pioneer species, increasing rapidly in numbers, drastically altering his habitat, and using up the resources on which he depends at a rapid and accelerating rate that definitely places a limit to their duration; in the case of some of them this limit is already being approached. It may be, however, that with the development of the faculty of intelligence man has within his power the choice of behaving either as a pioneer organism, destroying its habitat and consequently soon disappearing from it, or as a climax organism preserving its habitat and learning to live in equilibrium with it. If this is to happen, the sciences of geography and ecology must take the lead in determining how to establish a permanent equilibrium between man and his environment. Ecology must perform, on a scale not heretofore imagined, its function of integrating the data provided by other sciences, including the social sciences. Though the magnitude and difficulty of this task may make it seem impossible, our courage in attacking it may well determine the future of man on earth.

In summing up the symposium, Prof. Dudley Stamp said that every paper led to the same conclusion—with increasing pressure of population there must be conscious planning of land use and resources firmly based on scientific knowledge as well as on an appreciation of the varied needs and desires of human beings. This is particularly true of the humid tropics, where in many parts there are vast resources but few people, and so still hope of avoiding the worst blunders made in cooler lands. There must be mutual co-operation between planners and users as well as between different users. Our case is hopeless if we continue to regard the forester and agriculturist as enemies or the conservation of fauna and flora as inconsistent with the economic development of resources; the varied aims, all desirable in themselves, must be co-ordinated into one comprehensive plan.

The first thing that is required is an inventory and appraisal of resources, which should take the form of a factual land-use survey preceding any attempt at interpretation. A few examples of such surveys from the humid tropics are the magnificent reconnaissance maps of Ghana, the recently completed outline survey of the Sudan, the aerial survey of Pakistan, the recently commissioned air survey of Burma, the survey of Samoa carried out by the University of New Zealand, the fine detailed maps of Hong Kong prepared by the University, the detailed maps of Taiwan and, if one may stretch the tropics so far, the superlative detailed maps of Japan. All these follow broadly the recommendations of the Special Commission of the International Geographical Union approved at a meeting sponsored by Unesco in 1950.

The field covered by the symposium was an immensely wide one, but Prof. Dudley Stamp thought it covered only half the main problem. The other half is the human angle. The whole purpose of planning and rational land utilization is to secure an increased standard of living and a fuller measure of life for the people. What, in fact, do people want? Are our Western concepts of the standard of living the right ones? May not our search for efficiency be destroying values far more worth-while? He mentioned these points to emphasize his belief that the demographer, the sociologist and their many colleagues must carry out studies parallel to those with which the symposium had been concerned. It is difficult to plan unless one knows what one is planning for.

L. DUDLEY STAMP
P. W. RICHARDS

OBITUARY

Prof. H. A. Kluge

News has only recently been received of the death of Prof. Hermann A. Kluge on December 25, 1956. We are much indebted to Mrs. Helen Androsova, of the Zoological Institute, Leningrad, who has supplied the biographical details for this notice.

Kluge was born in Radom, Poland, in 1871, and graduated in 1896 at the University of Kazan, taking his master's degree and becoming *Privat-docent* there in 1899. He had already gained the gold medal of the University for his first research investigation (on the natural history of the freshwater Polyzoa), and had studied in 1897 at the Solovetski Biological Station on the White Sea. His major scientific interests for the rest of his life, the Arctic and the Polyzoa, were thus established. Between 1900 and 1907, in preparation for his doctor's degree, Kluge studied at the Zoological Station at Naples, and also at museums in Germany, Sweden, Denmark and England, where he paid particular attention to the collections of Polyzoa from the various oceans.

Returning to Russia, Kluge began to work on the previously unstudied collections of Polyzoa from Russian seas in the Zoological Museum (now Institute) of the Academy of Science at Leningrad. He continued this work throughout his life, and the resulting series of papers demonstrated the existence in Russian Arctic waters of some 350 species of Polyzoa, many of them new. Two important contributions, on which he had worked for many years, are to be issued posthumously. Kluge's investigations also extended to the Polyzoa of West Greenland and the Antarctic. The care and accuracy of his descriptions and fine drawings, which are typical of all his work, are well seen in his monograph (1915) of the Anascan Polyzoa of the Deutsche Südpolar Expedition of 1901–3, perhaps the best known of all his publications to European workers. He also wrote on such little-studied groups as the Kamptozoa, *Rhabdopleura* and the cirripede *Dendrogaster*.

But all this was only part of Kluge's scientific life. From 1908 until 1933 he was director of the Murman Biological Station in Kola Bay, where he remained as a scientific worker after his retirement. Though not a large institution, it has been described as a model of its kind, with an excellent aquarium, a good library and museum, and well equipped for marine biological investigations. In 1934 Kluge visited the north of Novaya Zemlya, where he spent the winter at the polar station at Cape Zhelaniya. He was also one of the founders of the Arctic Museum in Leningrad, of which he was director for some time.

Kluge devoted his life and energy to the study of the zoology of the austere far north. Our knowledge of the biology of the Arctic Ocean owes much to him.

NEWS and VIEWS

Sir James Swinburne, Bart., F.R.S.

Sir James Swinburne celebrated his hundredth birthday on February 28. Sir James, who until 1953 was chairman of Bakelite, Ltd., and who is now honorary president of the Company, is a distinguished engineer and one of the world's pioneers in the field of synthetic resins. His original work on phenolic resins at the beginning of the century made a major contribution to the development of the modern plastics industry. During his long life Sir James Swinburne has had many interests. In addition to being a Fellow of the Royal Society, he is past president of the Institution of Electrical Engineers, a past president of the Faraday Society, and a member of the Institution of Civil Engineers. He has always been interested in sociology and among his publications is the work "Population and the Social Problem". He has also been keenly devoted to music, and one of his early interests was the electric organ. Another of his hobbies is horology, and he has published books and papers on this subject. Sir James has now retired from active occupations to Bournemouth.

Social and Preventive Medicine at Belfast: Prof. A. C. Stevenson

Prof. A. C. Stevenson, head of the Department of Social and Preventive Medicine in The Queen's University, Belfast, will vacate his chair on April 1 to take up a new appointment as director of a Medical Research Council Population Genetics Unit. Prof. Stevenson joined the Department in 1948, after holding the post of senior lecturer in public health at the London School of Hygiene and Tropical Medicine. Prof. Stevenson has taken an active interest in the affairs of the Institute of Clinical Science, in which his Department is housed, which has given him ample opportunities for research in the field of genetics. Fortunate in having a defined population of convenient size for study in Northern Ireland, he has made a detailed study of the distribution of several harmful genes, including those involved in the transmission of myoclonic epilepsy, muscular dystrophies, congenital malformations, achondroplasia, epiloia, rheumatic fever, deaf mutism, retinoblastoma and tylosis palmaris et plantaris. Prof. Stevenson is the author of "Recent Advances in Social Medicine", published in 1950 by Churchill (London). In 1953 he was one of a team of medical scientists which visited Indonesia to study the public health problems and needs of that country for the World Health Organization.

The increasing hazards from ionizing radiation have directed attention to the fact that we have very few data on the genetic effects of radiation on human beings. Further information is required on the genetic structure of human populations and there is an urgent need for the collection of more information on fertility, consanguinity and mortality. The formation of a Medical Research Council Unit for the study of population genetics is a step in the right direction, and Prof. Stevenson's experience in Northern Ireland should stand him in good stead as head of the new Department.

Dr. J. Pemberton

Dr. John Pemberton, reader in social and industrial medicine in the University of Sheffield, has been appointed to succeed Prof. Stevenson. After working with Sir John (now Lord) Boyd Orr at the Rowett Research Institute, Aberdeen, in charge of a mobile nutritional research team, he went to Sheffield in 1940 as medical first assistant at the Royal Hospital, becoming medical tutor in 1941. During this time he maintained his interest in nutritional matters, working with Prof. H. A. Krebs on the extremely important experiments on deficiency of vitamin C in human volunteers. In 1946 he was appointed senior lecturer in medicine (social aspects) and student health officer in the University. In the next few years he carried out some extremely valuable studies on illness in general practice and socio-medical studies of hospital in-patients. In 1949 Dr. Pemberton joined the newly formed Department of Social and Industrial Medicine at Sheffield as senior lecturer, becoming reader in 1957. He has maintained contact with the hospital by accepting appointments as honorary consultant physician to the City General Hospital, where he has beds, and to the United Sheffield Hospitals, where he ran an out-patient clinic. He has played a most important part in developing the teaching and research programme of the Department, being particularly concerned with the running of the social medicine clerkship, and with the organization of case demonstrations and colloquia. With Prof. W. Hobson and Dr. H. Droller he helped to organize a medical survey of old people in their homes in Sheffield. In 1955 the results of this work were published in a book, "The Health of the Elderly at Home", of which he was joint author, and he was awarded jointly a prize of £100 for original work in geriatrics by the Ciba Foundation.

During 1953 Dr. Pemberton visited the United States to study teaching methods in American medical schools, and in 1954 spent a year at Harvard School of Public Health, working on the epidemiology of chronic bronchitis. His work in the United States resulted in his founding, with Dr. Harold Willard, the International Corresponding Club, of which he is the co-secretary. The Bulletin issued by the Club has been an outstanding success in making known to workers all over the world the developments in teaching and research which are going on in social medicine. In September 1957 he organized an International Study Group in Holland, financed by the Rockefeller Foundation. In 1957 a Medical Research Council group for epidemiological research on air pollution was formed in Sheffield, with Dr. Pemberton as director. His recent published work has been concerned with geriatrics, air pollution and respiratory disease.

National Physical Laboratory : Dr. E. Lee

Dr. Edward Lee, who is at present director of operational research in the Royal Naval Scientific Service, has recently been appointed to the new post of deputy director of the National Physical Laboratory. The deputy director will assume the main responsibility for work in the National Physical Laboratory which is closely geared to immediate demands from industry. Dr. Edward Lee was educated at Consett Grammar School and graduated at the University of Manchester with first-class honours in physics. After taking an M.Sc. degree at Manchester and a Ph.D. at Cambridge, he joined the Royal Naval Scientific Service in 1939 and was posted to the Admiralty Research Laboratory. In 1946, Dr. Lee joined the Defence Research Policy Staff at the Ministry of Defence and from then until 1951 his work was mainly concerned with relating Service research programmes to the scientific effort available and Service requirements. He has been director of operational research at the Admiralty for the past three years.

Reorganization of the National Physical Laboratory

During 1957, a comprehensive review of the organization and programmes of work of the National Physical Laboratory was carried out by a committee of the Research Council of the Department of Scientific and Industrial Research. As a result, certain changes in organization will be introduced about the end of March. One of the most important is a reorganization of the work at present carried out in the Divisions of Electricity, Metrology and Physics and in the Test House. These four units will be replaced by three new Divisions to be called Standards, Applied Physics and Basic Physics.

The Standards Division will be responsible for all fundamental work on standards of length, mass and time ; of electrical and magnetic quantities and also of temperature. Basically, it will consist of the present Metrology Division, expanded to include certain work on standards now carried out in the Electricity and Physics Divisions. The superintendent will be Dr. H. Barrell, at present in charge of the Metrology Division. The Applied Physics Division will be responsible in general for work in the field of classical physics of fairly immediate value to industry (excluding optics, which will continue in the Light Division). The principal areas covered will be electrotechnics, acoustics, heat and radiology. Test House, which has hitherto come under Administration, will become an integral part of this Division, but will preserve its identity under Mr. H. Bowley. The superintendent of the Applied Physics Division will be Dr. B. Wheeler Robinson, at present in charge of the Physics Division. The Basic Physics Division will be responsible for pioneering developments in certain branches of non-nuclear physics which have potential industrial applications in the less immediate future. The post of superintendent of this Division is at present vacant.

Expansion of Universities in Britain

A provisional building programme for university expansion, totalling £60 million during 1960–63, and including the foundation of a University College of Sussex, has been authorized by the Chancellor of the Exchequer. Announcing this in the House of Commons on February 20, Mr. Heathcoat Amory said that the programme would be subject to review if the economic situation changes substantially. The increase contemplated in the current rate of building is necessary if Britain is to secure the full benefits of future advances in science and technology, and it should be possible to achieve an increase from 106,000 to about 124,000 students by the mid-1960's, with a possible temporary rise of 10 per cent in the second half of the decade, an increase which may well prove to be permanent. Nearly two-thirds of the expansion will be devoted to faculties of science and technology of the existing universities and colleges of technology, which will enable the figure recommended by the Committee for Scientific Man-power to be reached and the number of scientists and engineers to be doubled. The education estimates, Mr. Amory added, would be £26·5 million higher next year.

In a written answer to a question in the House of Commons on the same day, Mr. Amory said that most universities are apparently dissatisfied in varying degrees with the grants allocated to them by the University Grants Committee, especially for the first two years of the quinquennium. The quinquennium settlement provides, however, for grants 8 per cent higher in the current academic year than in 1956–57, rising by a further 30 per cent over the next four years. To these will be added supplementary grants in respect of the cost of salary awards effective from last August, making the total grant 20 per cent higher in 1957–58 than in 1956–57.

It is proposed that the University College of Sussex should be built at Brighton, where the Corporation has offered a site of about 150 acres at Stanmer Park on the Lewes Road. Negotiations between the University Grants Committee and a committee representing the five local education authorities of Sussex and their education officers are at present in progress.

Nuclear Reactor Safety

The Parliamentary Secretary to the Minister of Power, Sir Ian Horobin, in a written reply in the House of Commons on February 10, said that the Government intended to introduce legislation to ensure, by a system of licensing and inspection, that nuclear reactors on land were effectively subject to control in the interests of public safety. Owners of such reactors would, like the Atomic Energy Authority, be required to prevent damage to property or personal injury from radioactive contamination and would be liable to pay compensation for such damage even from an unavoidable accident, except to the extent to which there was contributory negligence on the claimant's part. It was proposed to limit compensation in respect to any one incident to £5 million for each installation, and the insurance market was prepared to provide the necessary cover. The liability of the Atomic Energy Authority would not be affected, but problems of reactors in ships, submarines and aircraft required further study with regard particularly to the international aspects.

Technical Co-operation in Africa South of the Sahara

In a written answer in the House of Commons on February 5, Mr. Ian Harvey, replying for the Secretary of State for Foreign Affairs, said that the Government and other members of the Commission for Technical Co-operation in Africa South of the Sahara have agreed to set up a Foundation for Mutual Assistance in Africa South of the Sahara. The Foundation is designed to facilitate and encourage the provision of technical assistance for that region and would be inaugurated at Accra at the end of February. The House would be asked to approve provisions for a United Kingdom contribution of technical assistance through the Foundation, which would be under the general direction of the Commission with a combined secretariat.

Land for Service Requirements

The Land Powers (Defence) Bill, which is the first major Bill to implement the Government pledges in the debate on the Franks report, seeks to terminate Defence Regulations relating to land and to make permanent provision for the much more limited powers required for defence purposes in time of peace. Speaking in the House of Commons on February 10 on the second reading of the Bill, Mr. G. de Freitas said that in England, War Office holdings amounted to 1·47 per cent of the land; in Wales, 1·07 per cent; and in Scotland, 0·24 per cent. Asking for more information on the Government's policy on land for Service training, he stressed the need for knowledge of total Service requirements if supplementary requests were to be handled intelligently. The tendency should be for less and less land to be required by the Services but, after referring to the co-operation during the past year with the Nature Conservancy, of the War Office at Braunton Burrows and of the Royal Air Force at St. Kilda, as outstanding examples of the possibility of meeting the requirements of the Services side by side with those of scientific research, Mr. de Freitas pointed out that there were examples to the contrary. While accepting the general principle of the Bill, it was essential to see that the safeguards offered to the public were effective and that the objections of local authorities, the National Parks Commission and other bodies could be thoroughly examined. In his reply on the debate, the Attorney-General, Sir Reginald Manningham-Buller, said that the power to make representations to the Manoeuvres Commission, which was thereupon required to hold at least one public inquiry, was likely to be a much more effective way of protecting the amenity, ornithological and other interests in the land in an area covered by an Order in Council.

New Roads

Replying on a debate in the House of Lords on February 13 on the acquisition of land for roads, the Minister without Portfolio, Lord Mancroft, while agreeing that the announced programme of expenditure on roads of £240 million for the period 1958–62 was not big enough, claimed that it was commensurate with our resources of finance and man-power. Forty large projects on the Great North Road would be authorized by the end of the financial year and work on many was already in progress. Work on the Leicester by-pass, to cost nearly £4 million, was due to finish by the end of 1959. The Kingsferry Bridge in the Isle of Sheppey would cost more than £1 million, the northern approach to the Blackwall Tunnel nearly £2 million, the Birmingham Ring Road, the first stage of which should be finished this year, about £15 million, and work would start in March on a section of the London–Yorkshire motorway, which would be 53 miles long, take 19 months to complete and cost £15 million. The Ross Spur, to start on March 9, would take two and a half years. Much detailed work was involved in the preparation needed for the acquisition of land for road schemes, and the Government was trying to accelerate this work. He hoped in future it would be possible to provide local authorities with a programme approved in principle for three or four years ahead, which would enable them to work out details of the schemes and acquire property in time for the Minister to authorize the grant in the year in which he originally expected to make financial provision. After stressing the importance of flexibility, Lord Mancroft said that the Minister of Transport and Civil Aviation had set up a special planning section which was preparing a twenty- to thirty-year master plan for roads.

The Physics of Fluids

The Physics of Fluids (1, No. 1 (January–February, 1958). Pp. ii+72. Published bi-monthly. Annual subscription rate : 11 dollars. New York : American Institute of Physics, 1958) is a new bi-monthly publication of the American Institute of Physics. It will publish original research papers on the dynamics of flow, waves and shocks and also on the statistical thermodynamics of the fluid state. Particular attention will be given to the mutual interaction between the flow of fluids and electromagnetic phenomena or chemical or nuclear processes. The term 'fluids' is applied by the editors to liquids, including liquid helium, to compressed and rarefied gases and to plasma. The new periodical may owe its existence to the necessity of relieving *The Physical Review* and *The Journal of Chemical Physics*. Research workers in the field of fluid physics will welcome the increase in facilities for publishing their work.

There is a tendency to regard hydrodynamics and the molecular theories of liquids—to name only two significant examples—as somewhat outmoded and to appreciate them only in connexion with their engineering applications. Evidence to the contrary is apt to be overlooked when it is scattered over a number of different journals. In contrast, the first issue of *The Physics of Fluids* presents papers on topics such as the theory of bubble chambers, the effect of radiation on the propagation of shock waves, stability in magneto-hydrodynamics and the statistical quantum mechanics of the electron gas. It is clearly shown that fluid physics is closely connected with contemporary fundamental research. The American Institute of Physics intends to publish *The Physics of Fluids* at monthly intervals if need arises. In the interest of progress in a fascinating branch of science we hope this plan will materialize at an early date.

National Museum, Bloemfontein

The annual report of the National Museum, Bloemfontein, for the year ended March 31, 1957, reflects the activities of a progressive institution. New buildings include a board room, enlargement of the library, and a thatched shelter to protect the exhibits of rock engravings. In addition, the new displays include a diorama of wildebeest, a large diorama of Free State animals and Matjes River material. It is pleasing to note that the appointment of a book-keeper/clerk has enabled the director to give more time to research and the preparation of exhibitions in the Museum.

Clinical Use of Hormones

Information about hormones tends to be widely dispersed among specialized publications, and it is not easy for the ordinary clinician to obtain a balanced and up-to-date view of their status in medicine. *The Practitioner* (180, 5 ; January 1958) has therefore published a symposium of twelve short reviews, dealing with all the hormones now in general use with the exception of adrenaline. The articles are mainly of a practical nature, and discuss such questions as dosage, types of commercial preparations available, and indications and contra-indications for their use. In addition, in the small amount of space available, they provide a surprising amount of general scientific information on the nature and mode of action of the hormones, and they include short bibliographies of important papers and reviews.

The British Lichen Society

A society for the promotion of the study and conservation of lichens, under the title of the British Lichen Society, was formed at a meeting held at the British Museum (Natural History), South Kensington, on February 1, by kind permission of the Trustees. It is hoped eventually to publish a journal ; but in the meantime it is intended to issue lichenological notes and news in the form of a mimeographed bulletin. Particulars can be obtained from the Honorary Secretary, Mr. A. E. Wade, Department of Botany, National Museum of Wales, Cardiff.

University News : Bristol

The following appointments have been made : Dr. T. H. K. Barron, lecturer in physical and inorganic chemistry ; Mr. R. Bradshaw, lecturer in geology ; Dr. R. G. Chambers, senior lecturer in low-temperature physics ; Dr. J. Tinkler, lecturer in aeronautical engineering.

The following have resigned : Prof. G. C. Drew, from the chair of psychology on his appointment to the chair of psychology at University College, London ; Dr. E. J. Field, lecturer in anatomy, on his appointment as senior lecturer in neuropathology, King's College, Newcastle, and the Royal Victoria Infirmary ; Dr. K. Stewartson, reader in applied mathematics, on his appointment to the chair of applied mathematics at the University of Durham ; Dr. H. A. Thurston, lecturer in mathematics, on his appointment to the University of Vancouver.

The following gifts have been received : £7,773 from the British Empire Cancer Campaign for cancer research to be carried out in the Departments of Pathology, Physiology and Surgery, in 1958 ; £1,000 per annum for a period of two years from Messrs. Kodak, Ltd., to the Department of Physics as an extension of the grant in support of experimental work on the physical properties of silver halides ; £967 from the Agricultural Research Council to the Department of Physiology as renewal of the grant in aid of research on bovine acetonæmia for a third and final year from April 1.

Liverpool

Dr. C. A. Clarke has been appointed to a readership in the Department of Medicine.

London

Dr. M. L. Thomson, senior lecturer at the London School of Hygiene and Tropical Medicine, has been appointed to the University readership in applied physiology tenable at that School. The title of professor of pharmacology in the University of London has been conferred on Dr. George Brownlee, in respect of his post at King's College. The title of professor of biochemistry in the University of London has been conferred on Dr. William Robson in respect of his post at King's College. The title of professor of pharmacology in the University of London has been conferred on Dr. Miles Weatherall in respect of his post at the London Hospital Medical College. The title of reader in dental medicine in the University of London has been conferred on Mr. B. E. D. Cooke in respect of his post at Guy's Hospital Medical School. The title of reader in biochemical genetics in the University of London has been conferred on Dr. Harry Harris in respect of his post at the London Hospital Medical College. The title of reader in pharmacology in the University of London has been conferred on Mr. J. P. Quilliam in respect of his post at St. Bartholomew's Hospital Medical College.

Sydney

Prof. J. H. Gaddum, professor of pharmacology at the University of Edinburgh, has been appointed third visiting professor of pharmacology in the University of Sydney. Prof. Gaddum will leave for Australia about the middle of April and will spend approximately two months in Sydney. During his stay in Australia he will lecture in Sydney and other capital cities and will visit the Australian National University in Canberra. A fund has been established by the pharmaceutical manufacturers of Australia to enable the University of Sydney to invite a guest professor in this subject each year.

Vancouver

Dr. R. D. Russell, of the University of Toronto, has been appointed associate professor of geophysics in the University of British Columbia. A chair of geophysics, within the Department of Physics, was established last year by the appointment of Prof. J. A. Jacobs. Research at first will be mainly in the fields of isotope geology and geomagnetism.

The Night Sky in March

Full moon occurs on Mar. 5d. 18h. 28m. u.t., and new moon on Mar. 20d. 09h. 50m. The following conjunctions with the Moon take place: Mar. 8d. 21h., Jupiter 2° N.; Mar. 12d. 18h., Saturn 3° S.; Mar. 15d. 11h., Mars 6° S.; Mar. 16d. 11h., Venus 1° S. Mercury is favourably placed for observation at the end of the month, setting at 19h. 0m. on Mar. 15 and 20h. 20m. on Mar. 31. Its stellar magnitude is $-1\cdot3$ on Mar. 15 and $+0\cdot4$ on Mar. 31. Venus is a morning star, visible low in the south-east before sunrise. It rises at 4h. 50m., 4h. 30m. and 4h. 10m. on March 1, 15 and 31, respectively; its stellar magnitude is $-4\cdot2$. During the month its distance from the Earth increases from 37 to 58 million miles and the visible portion of the apparent disk from 0·227 to 0·450. Mars rises at 4h. 55m., 4h. 30m. and 4h. 00m. at the beginning, middle and end of the month, respectively; it will be difficult to observe. Jupiter rises at 22h. 20m., 21h. 20m. and 20h. 10m. on March 1, 15 and 31, respectively; it is east of Spica. The stellar magnitude of Jupiter is $-1\cdot9$, its distance from the Earth on March 15 being 430 million miles. Saturn rises at 3h. 05m., 2h. 15m. and 1h. 10m. at the beginning, middle and end of the month, respectively; it is east of θ Ophiuchi. It has a stellar magnitude of $+0\cdot7$ and a distance of 930 million miles from the Earth on March 15. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Mar. 1d. 22h. 16·7m., λ Gem. (*D*); Mar. 3d. 18h. 31·5m., ϰ Cnc. (*D*); Mar. 11d. 03h. 02·0m., ν Sco. *m.* (*D*); Mar. 11d. 03h. 31·9 m., ν Sco. *m.* (*R*); Mar. 26d. 22h. 01.4m., 104 Tau. *m.* (*D*); Mar. 30d. 20h. 58·0m., A^2 Cnc. (*D*). *D* and *R* refer to disappearance and reappearance, respectively. The vernal equinox occurs on Mar. 21d. 03h.

Announcements

About £50 is available from the Clough Memorial Research Fund of the Edinburgh Geological Society for geological research in Scotland and the north of England (Northumberland, Durham, Cumberland, Westmorland and Yorkshire) during the period April 1, 1958–March 31, 1959. Applications, stating the nature of the proposed research, should be sent before March 31 to the Secretary, Clough Memorial Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh 1.

The Ministry of Agriculture, Fisheries and Food and the Department of Agriculture for Scotland propose to award, for the academic year beginning October 1, 1958, a number of postgraduate scholarships in the various branches of husbandry, farm management, agricultural economics, statistics, agricultural and dairy engineering, rural estate management and land economics. Awards will also be offered in agricultural science for students intending to pursue a course of postgraduate instruction. The closing date for receipt of completed application forms is March 31. Further particulars and forms of application can be obtained from the Ministry of Agriculture, Fisheries and Food, Room 284, Great Westminster House, Horseferry Road, London, S.W.1, or the Department of Agriculture for Scotland, St. Andrew's House, Edinburgh 1.

A symposium on "Science and Society" will be held in the William Beveridge Hall, Senate House, University of London, on March 19, under the auspices of the Royal Institute of Chemistry, the Institute of Biology and the Institute of Physics. Prof. P. M. S. Blackett will take the chair. The main speakers will be: Prof. L. T. Hogben ("Science and its Social Functions"); Prof. A. Haddow ("The Social Dangers of Science"); Dame Kathleen Lonsdale ("The Social Place of Science"); Mr. Anthony Smith, *Daily Telegraph* (in place of Mr. L. J. F. Brimble, *Nature*) ("The Deployment of Scientific Effort"). Further information can be obtained from the Secretaries of any of the above Institutes.

The British Social Biology Council is holding a one-day conference on "The Making of a Scientist" in the North Hall Suite, Victoria House, Southampton Row, London, W.C.1, on March 22. The conference will bring together men and women from the schools, universities, industries and public services who are concerned with the training of scientists and their employment. It will be open to anyone who is interested in education and science. Tickets for admission are obtainable from the Secretary, British Social Biology Council, 69 Eccleston Square, London, S.W.1. The programme for the morning, under the chairmanship of Mr. J. O. Blair-Cunynghame (National Coal Board), will consist of lectures on: "The Position of the Science Graduate in Industry" by Mr. E. A. Cooke (Imperial Chemical Industries, Ltd.); "Scientists in the Engineering Industry" by Mr. G. S. Bosworth (English Electric); "Fostering the Scientific Attitude" by Prof. J. Z. Young (University College, London). In the afternoon the chairman will be Mr. A. Rodger (Birkbeck College) and the lectures will be on: "Human Relations and Scientific Method" by Miss M. L. Johnson (University College, London); "Industry and the Artist" by Mr. B. Archer (Central School of Arts and Crafts); "Teaching Science: the Need for Research" by Mr. R. Weatherall (Eton College). There will be opportunities for questions and discussion.

Errata. In the communication entitled "Isotopic Tracer Method for measurement of Iron lost into and re-absorbed from Gastro-intestinal Bleeding Lesions" by M. Roche *et al.* (*Nature*, 180, 1278; 1957), par. 3, equation 2 gives the hæmoglobin in gm./100 c.c. and not mgm./100 c.c. as printed; par. 7, line 4, the footnote reference should be 4.

COLUMN PACKINGS FOR GAS CHROMATOGRAPHY

THE second in the series of informal symposia organized by the Gas Chromatography Discussion Group associated with the Institute of Petroleum was held in the Organic Chemistry Laboratory, Cambridge, on October 4. More than two hundred participants attended and four papers were presented. Local organization was carried out by Dr. J. H. Purnell.

After a short welcoming address by Prof. R. G. W. Norrish, Dr. A. T. James, chairman of the Discussion Group, outlined a new organization for the Group which it is hoped to put into effect shortly. This would allow a definite membership open to all workers in the field, and many of those present indicated their interest in the scheme. He also directed attention to the Second International Symposium on Gas Chromatography being arranged by the Group in Amsterdam during May.

Dr. J. J. van Deemter presented an introductory paper on column packings and peak sharpness. He considered the factors contributing to peak broadening in the light of current theories of gas chromatography and discussed the effects of gas velocity, sample size, support particle size and stationary phase proportion, on column efficiency. After considering the latest form of the van Deemter equation, relating the height equivalent to a theoretical plate (HETP) and diffusional effects, he pointed out that a variation in film thickness on the packing would also lead to peak broadening. This effect is probably particularly significant when low proportions of stationary phase are employed. An interesting observation was the fact that resistance to mass transfer in the liquid phase was not, in all cases, dependent on the viscosity of the stationary phase. With silicone oils, variation of viscosity over a hundred-fold range had little effect on column efficiency. Dr. A. J. P. Martin suggested that with linear polymers increasing chain length has little effect on the diffusivity of small molecules.

Mr. R. P. W. Scott then presented a paper describing an experimental investigation of many of the parameters determining column efficiency considered by the previous speaker. The hydrogen flame detector had been employed with a mixture of 75 per cent hydrogen plus 25 per cent nitrogen as carrier gas and a single stationary phase Apiezon Oil *A* supported on Johns-Manville *C*22 insulating brick. An examination of columns prepared from brick powders of different particle size with a constant proportion (20 per cent weight) of stationary phase at 78° C. had shown, as would be predicted by the van Deemter theory, that the smaller particles are more effective. In addition, the importance of a narrow particle size distribution was demonstrated. The best stationary phase/support ratio for short columns a few feet long was found to be 20 per cent w/w, but theoretical plates values above about 3,000 were best obtained by the use of long columns with low proportions of stationary phase, that is, 5 per cent w/w and below. Data were given for a 25-ft. column having an efficiency of 10,000–12,000 theoretical plates which would partially resolve *para*- and *meta*-xylenes on a volatility basis.

The afternoon session opened with a paper by Mr. C. S. G. Phillips on the use of metal salts as column liquids. Copper and zinc stearates and nickel oleate had been examined, the stearates at 156° C. and the nickel salt at 97° C. Although with hydrocarbons and other non-polar compounds separations were similar to that obtained with conventional stationary phase liquids, with amines, for example, strong co-ordination forces to the metal atoms produced new types of separations markedly dependent on steric factors. Several thousandfold differences in retention times could be obtained in favourable cases. Mr. Phillips cited the case of the separation of 2,6-lutidene and α-, β- and γ-picolines. About two hundred thousand plates were required to separate these compounds, using only their volatility differences, but with zinc stearate at 150° C. less than five plates are sufficient. The results with these metal-salt columns could be related to studies of complex-ion formation in aqueous solutions and provide information on complexing equilibria.

In the last paper Dr. J. H. Purnell put forward, on behalf of the Gas Chromatography Discussion Group, further recommendations[1] concerning the presentation of gas-liquid chromatographic retention data. It was proposed that retention data be presented in one of the two following ways, each being adequate provided any additional information required for interconversion is also given.

(1) In tables of relative retention times for at least two temperatures (so far as is practicable) with, where possible, the partition coefficient or specific retention volume of the standard solute. A suitable graphical method is the plot of logarithm of relative retention times versus the reciprocal of the absolute temperature.

(2) In terms of a linear equation relating the parameter chosen to temperature, for example, by an Antoine equation

$$\log V^0_g = A/(t + C) + B$$

where t = temperature in deg. C. and A, B and C are constants. This may be done graphically, but where results are numerous and the line represents the experimental results with accuracy, the constants of the equation (with the temperature limits between which it has been found to hold) will allow calculation or replotting on a large scale. It is hoped that the detailed recommendations will be published shortly in *Analytical Chemistry*.

Before the meeting closed, the chairman asked Mr. McWilliams, a visitor from Australia, to describe briefly a new detector he had mentioned earlier in the proceedings. This employed a small flame at the exit from the column, as in the detector developed by R. P. W. Scott, but instead of flame temperature, the ionization current between the jet and a positive platinum-gauze electrode inserted in the flame was measured. Large changes in current occur on introducing vapour into the nitrogen/hydrogen mixture feeding the flame, and a detection limit of 1 part in 4×10^8 v/v was claimed. The sensitivity in the units proposed at the last meeting[2] was given as 3×10^7 mV. ml./mgm. with a noise-level of 0·2 mV.

D. H. Desty

THE BRITISH FLORA IN 1957

THE investigation of the British flora has passed through many phases. The past decade has been characterized mainly by concentration on detailed studies of individual species, or of small groups, making full use of the techniques of ecology, genetics and cytology as aids to taxonomy. In addition, there has been the detailed study of distribution organized by the Distribution Maps Scheme of the Botanical Society of the British Isles which has received the support of more than three thousand helpers. As a result of all this research, it has become more evident each year that the flora of the British Isles cannot be satisfactorily studied in isolation; it must be considered in relation to the European flora of which it forms a part. There has been an increasing tendency for British workers to make better use of Continental research, and to travel abroad to study the behaviour of British species overseas. It seems likely that this attitude will become the outstanding feature of the next phase of the study of the British flora, and that with the increased facilities of modern travel any remaining insularity will disappear.

It was in the belief that we are on the threshold of a change in emphasis, that exhibits on the relationship of the British to the European flora were a special feature of the Annual Exhibition Meeting of the Botanical Society of the British Isles on November 30. This was arranged in the lecture hall of the British Museum (Natural History), by kind permission of the Trustees, and was attended by 360 members and guests. There were fifty-nine exhibits.

The exhibit prepared by Prof. T. G. Tutin (Leicester) under the title of "Some Straightforward British Plants and their Continental Complexities" showed *Ranunculus bulbosus*, *Primula elatior* and *Helleborus viridis*. In Britain these provide no taxonomic difficulties, but the buttercup, characterized here by the swollen stem tuber, produces only a feebly developed bulb in the south of France, and no bulb at all in Spanish and Italian specimens; while the other two species exhibit subspecific variation in Europe with differences in habitat, distribution and morphology. Prof. D. A. Webb (Dublin) showed examples from the Irish flora of species which can only be understood by studying their behaviour in Spain. Thus, in Ireland, *Saxifraga hirsuta* hybridizes so freely with *S. spathularis* that it is very difficult to find the pure species; but in Spain the two are separated geographically, and much better differentiated ecologically. In Ireland, *Erica mackaiana* is sterile, producing only about one viable seed for every thousand flowers, but in Spain it sets seed freely but is self-sterile. It seems that both the Galway and Donegal populations may consist of a single clone.

Progress and problems of the projected "Flora Europæa"[1], which is expected to include descriptions of some 16,000–17,000 kinds of plants, were illustrated by Dr. V. H. Heywood (Liverpool). As examples of the difficulties of producing a condensed account of complex groups on modern lines, he showed series of *Anthyllis vulneraria*, and the clines in *Pinus nigra* aggr. Both have been the subject of voluminous literature; of the former, Jalas has published a recent treatment of part of the complex based largely on field and herbarium material; on the latter, ten papers on nomenclature have appeared during the past twenty-five years, but both require much work to produce suitable treatments over the whole area covered. The compilers of the "Flora Europæa" have many similar problems to face. Among the other exhibits which considered British plants in relation to their distribution or variation elsewhere were those provided by Dr. D. E. Coombe (Cambridge) on *Carex humilis*, N. K. B. Robson (Kew) on *Hypericum maculatum*, J. P. Savidge (Liverpool) on *Callitriche*, Dr. S. M. Walters (Cambridge) on *Carex* section *Distantes*, and Dr. E. F. Warburg (Oxford) on *Sorbus*. Fresh flowers and fruits from the Riviera were shown by Miss M. S. Campbell.

During 1957 there have been no important species added to the British list, but several very rare ones have been found in new localities. The most interesting of these is *Spiranthes romanzoffiana*, which was found in July on Dartmoor, and was exhibited by P. C. Hall and Mrs. B. Welch. This orchid was not previously known from England, and in some respects the Dartmoor plant is intermediate between the populations found in southern Ireland and those in northern Ireland and Scotland. R. A. Graham and R. M. Harley exhibited *Mentha* × *piperita* var. *sylvestris* from near Brixham, collected by K. Bull in 1954, as a mint not seen for 150 years. It was originally collected near Bath about 1790. *Poa bulbosa* was shown by J. Hodgson from near Frensham, Surrey. It is the first record of this usually maritime grass from the county since 1762, but although the new habitat is a suitable one, association with other species known to have been introduced suggests that the plant is not native here.

Considerable attention is now being devoted to the study of hybrids in the British flora. The old reproach, that if a plant proved difficult to name the easy way out was to call it a hybrid, is no longer true, and botanists are now investigating claims to hybridity with painstaking care. The British Museum (Natural History) exhibited type specimens of two hybrids new to science—*Potamogeton* × *cadburyae*, which is a cross between *P. crispus* and *P. lucens*, and *P.* × *pseudofriesii*, which is a cross between *P. acutifolius* and *P. friesii*. Both were described by J. E. Dandy and G. Taylor. An interesting example of a hybrid detected in the field was *Symphytum peregrinum* × *tuberosum* shown from Woodbridge, Suffolk, by E. Milne-Redhead (Kew). Synthetic hybrids in *Spergularia* were shown by J. A. Ratter (Liverpool). By artificial cross-pollination he produced *S. bocconi* × *salina* and *S. salina* × *rupicola*—in both there was complete failure to produce fruit, and flowering continued throughout the season. Dr. B. A. Hulme showed artificially produced hybrids in *Atriplex*. Using *A. patula*, $2n = 36$, *A. hastata*, $2n = 18$, and *A. littoralis*, $2n = 18$, as parents, she found that there was free crossing between *A. patula* and *A. littoralis*, but not between *A. patula* and *A. hastata*, and she was unable to produce *A. hastata* × *littoralis*.

P. M. Benoit had four exhibits of hybrids. *Festuca rubra* × *Vulpia myuros* was claimed as new to science. A single plant was found in Merioneth, morphologically intermediate, and completely sterile. *Cardamine flexuosa* × *hirsuta* he had synthesized, making successful crosses in both directions. *Myosotis caespitosa* × *scorpoides* he found in a marshy meadow at Dolgelley in 1956—this is new to the British Isles. He also had a very convincing exhibit of the common hybrid *Senecio aquaticus* × *jacobaea*, which is partially fertile and very variable and forms complex hybrid swarms. Dr. S. M. Walters and Miss A. Martin (Cambridge) showed an interesting study of *Calystegia sepium* and *C. sylvestris*. This was based on five populations in and near Cambridge for which they had scored measurements of parts of the flowers and arranged them on the principle of Anderson's "Hybrid Index". Both species are markedly incompatible, and small populations usually arise from a single clone and therefore set little or no seed, but seed is set in larger populations or those which are heterogeneous. Their analysis showed that morphologically intermediate populations of presumed hybrid origin occur frequently in the vicinity of Cambridge and presumably arose by cross-fertilization.

Two exhibits directed attention to new techniques. B. E. Juniper (Oxford) showed replicas of leaf surfaces obtained by the use of the electron microscope. These included, for example, *Oxalis corniculata* var. *atropurpurea* under a magnification of 34,000 linear. When the investigation of structures beyond the resolution of the light microscope is more advanced, new characters may be revealed to assist the work of taxonomists. D. E. Bradley exhibited a series of flowers of native orchids preserved by an embedding technique. After treatment in a colour-preserving solution, they were dried and embedded in transparent blocks of cold-setting 'Ceemar' resin.

Other aspects of British botany were represented by further exhibits, but it was clear that the Distribution Maps Scheme, the relationship to the European flora, and hybrids were the main interests of members of the Society in 1957. Progress made during the year as demonstrated by the exhibits represents a sound contribution to knowledge.

J. E. LOUSLEY

THE GEOGRAPHICAL ASSOCIATION

THE annual conference of the Geographical Association was held at the London School of Economics during December 31–January 3. Prof. P. W. Bryan, in his presidential address, fascinated and impressed a very large audience by a series of beautiful coloured photographs and his insistence that geographers must deal primarily with the landscape as a whole, including the interrelated parts of the physical and the cultural. With the whole landscape as their basis, research workers could then go on to a detailed consideration of particular features.

One of these particular features, the landscape of glacial erosion, received detailed treatment by Mr. Vaughan Lewis, of Cambridge, in an analysis of the recent work done on "Erosion by Cirque and Valley Glaciers". He felt that the most helpful assumption now is that frost shatter is most severe in bergschrunds and related features, such as the enclosed head-wall gap reached by the upper tunnel dug through Vesl-Skautbreen, Jotunheimen, in 1951, when melt-water falls on to rock that is still a degree or so below the freezing point. This occurs in spring or early summer in the few weeks before the temperatures in the rock, and ice in the neighbourhood of the bergschrund, are raised to the freezing point.

He also considered that if rotation occurs as a result of the great downward thrust of an icefall, bed abrasion may be increased locally, partly by this great downward pressure and probably more effectively by the higher velocity induced in the deeper lower layers of ice in contact with the bed. Ice has not sufficient strength to hold very small stones firmly enough to do much grinding and gouging of the much stronger rock, but if the boulders or blocks of rock are large, the ice can drag them past the rock with great force and produce correspondingly great erosion. If the rock is well jointed, this abrasion, coupled with frost shatter wherever low temperatures can reach the rock, may account for the bulk of glacial erosion. But if the rocks are massive and like granites and certain metamorphic rocks consolidated under great pressure, then joints may form near the surface—the primary ones lying parallel to the surface—as a result of the release of pressure on the removal of the overlying rocks. The rocks may burst upwards, as it were, an action which has been noted in certain New England quarries. This action may help the recession of the walls bounding valley glaciers. It is hoped that Mr. Lewis's findings may be published in full at a later date.

One aspect of the cultural landscape, namely, urban geography, received detailed treatment in several lectures and constituted the main theme of the conference. Prof. A. E. Smailes, of Queen Mary College, London, read a paper on "Urban Studies" and paid tribute to the pioneer work that had been done on spheres of urban influence and in many detailed studies of urban morphology. The latter, largely based on maps, had greatly added to our knowledge of towns, but sometimes the use of a two-dimensional map failed to convey the true character of an urban area. It could easily ignore what Prof. Smailes called 'the texture' of a town by failing to emphasize the three-dimensional aspect of buildings. With a wealth of illustrative matter and descriptive detail, he gave examples of various types of towns viewed in three dimensions and went on to an analysis of the main forms of urban growth in the past century. He distinguished, for example, with the aid of air photographs, the terrace ribbing pattern of much Victorian housing, the villa studding of more recent housing, and finally the block clumping of flats in modern times.

Prof. E. W. Gilbert, of Oxford, in a lecture on "English Seaside Towns", stated that roughly 2½ million people now lived permanently in these places. After describing their diverse origins and present functions, he discussed the many lines of research on them now proceeding in several universities. He made a special plea for more work on the medical geography of resorts, emphasizing that little was known of the precise meaning of the 'bracing' and 'relaxing' qualities of places and of their exact influence on the human body. He felt strongly that more attention should be given to descriptive geography and especially to the aspect of towns. He urged geographers to analyse the beauty of urban and rural scenery and not to be afraid of expressing their own subjective feelings. Educated geographical opinion should unite to preserve the beauty of both coast and seaside Regency buildings.

Mrs. D. Monteith gave a fascinating account of the development of Saffron Walden, showing how the main-line railway had avoided the town and had greatly impeded its subsequent growth. Later in the week, Mrs. Monteith took a party of members to Saffron Walden to explain in more detail the methods and results of her survey. Dr. A. Garnett gave a detailed study of atmospheric pollution as a factor of urban geography, and Mr. G. F. A. Wilmot introduced a different facet by considering the scope of railway geography in urban areas and illustrating it by a coach tour to examine some aspects of railway development in North London. Prof. Beaver introduced yet another aspect by analysing the changing industrial landscape of Great Britain, emphasizing the great part that modern technology is playing in modifying the effects of industrialization.

The teaching side of geography also received suitable attention. A very lively discussion on the effect of Ordinary Level examinations on the teaching of geography opened the conference, and on the last day of the lectures Miss P. M. Jeffery gave a lesson showing the follow-up of a field expedition in an urban area, and Mrs. I. L. M. Long presented the results of the research project into "The Interpretation of Geographical Pictures by Secondary School Children".

The last day of the conference was devoted to a series of excursions which included, in addition to the two already mentioned, a tour of the sites of London's former airports, a tour of metropolitan Essex, a traverse by coach to Cambridge, and a walking expedition to examine the site and function of the City of London. R. C. Honeybone

THE NATIONAL PHYSICAL LABORATORY

REPORT FOR 1956

THE annual report* for 1956 of the National Physical Laboratory, Teddington, gives an excellent survey of the fundamental and applied research carried out during the year in the nine Divisions and Test House of the Laboratory. It contains also the report of the Executive Committee which was presented to the General Board at its meeting on May 23, 1957, the annual open day of the Laboratory (see *Nature*, **180**, 166; 1957).

The Executive met seven times during the year, but refrained from taking any major policy decisions while changes in the directorship of the Laboratory were taking place. Sir Edward Bullard, whose resignation as director became effective on December 31, 1955, was succeeded by Dr. R. L. Smith-Rose, who continued as acting-director until September 14, 1956, when Dr. G. B. B. M. Sutherland assumed his appointment as director. The arrangement whereby certain members of the Executive Committee form panels to visit and report on the scientific divisions of the Laboratory was continued, and reports were considered during the year from the panels which visited the Mathematics, Metallurgy and Physics Divisions. Both the chairman of the mathematics panel and the superintendent of the Mathematics Division made representations to the Committee that the supply of trained numerical analysts was inadequate to meet the increasing use of high-speed computers and that staff was not available in the universities to provide for the teaching of numerical analysis on an adequate scale. A panel, with Sir Charles Darwin as chairman, was therefore set up by the Committee, to consider this matter and to advise on whether special facilities for the training of numerical analysts should be provided at the Laboratory, in addition to using other means elsewhere.

Two new buildings, one for radiological work and the other for low-temperature research, were completed during 1956 and occupied by the Physics Division. The 24 in. × 20 in. high-speed wind tunnel in the Aerodynamics Division was put into operation and the construction begun of a new workshop on the West Aero site and of a new road and entrance to the Laboratory from Hampton Road. Good progress has been maintained on the new Ship Hydrodynamics Laboratory at Feltham and the completion date for the whole project is forecast in the report as early 1959. With regard to future building requirements of the Laboratory, it is still required that priority be given to the provision of a new library, lecture hall and canteen, and accommodation for an expanded Control Mechanisms and Electronics Division.

Four new booklets, Nos. 13, 14, 15 and 17, in the series "Notes on Applied Science" were published during the year, in addition to the proceedings of the symposia on "Boundary Layer Effects", "Cavitation in Hydrodynamics" and "Creep and Fracture of Metals at High Temperatures". In the series "Units and Standards of Measurement employed at the N.P.L." a new edition of Part 1 (on length, mass, time-interval, etc.) and a revised edition of Part 2 (on light) were issued. Three books, "Mass Spectrometer Researches", "Tables of Weber Parabolic Cylinder Functions" and "Wage Accounting by Electronic Computer" were published, of which the last mentioned has been so well received that it has already been reprinted three times. This work consists of the first report of the Interdepartmental Study Group on the Application of Computer Techniques to Clerical Work. Several earlier publications have also been reprinted including, in particular, the proceedings of the 1953 symposia on "Engineering Dimensional Metrology" and on "Automatic Digital Computation".

* Department of Scientific and Industrial Research. Report of the National Physical Laboratory for 1956. Pp. viii+104+5 plates. (London: H.M. Stationery Office, 1957.) 5s. net.

The work of directing the attention of other organizations to the research and development proceeding at the Laboratory was extended. The two liaison officers paid 145 visits mainly to commercial organizations, and about a hundred return visits were made to the Laboratory for the interchange of information. 114 lectures were given by members of the staff of the Laboratory to various scientific and similar bodies and 156 scientific articles, details of which are given in the report, were published. Several items illustrating the work of the Laboratory were exhibited at the Physical Society's annual exhibition of scientific instruments and apparatus, and at the Factory Equipment Exhibition. In addition, demonstrations were given at the Royal Society soirée and at conversaziones arranged by the Institution of Civil Engineers and the Institution of Electrical Engineers. Visitors to the Laboratory included three parties of Russians, two of which were concerned with aerodynamics; a delegation of members of the West German Parliament; and parties of senior officials from the Ministry of Pensions and National Insurance and from the Treasury in connexion with the possibility of carrying out pay-roll work by digital computer. Thirty-four members of the senior staff made official visits overseas—ten to North America and twenty-four to countries in Europe. The British national copy of the international metre was taken to the International Bureau of Weights and Measures in Paris and, after re-graduation, was re-calibrated at the Bureau before its return to the Laboratory in December. Details of the visits, together with the names of the members of the general board, executive committee, Froude Ship Research Sub-committee, the Advisory Committee on Radioactive Standards, the Panel on Training of Numerical Analysts, and the senior members of the staff of the Laboratory are included in the annual report.

The individual reports of the various sections of the Laboratory make interesting reading. Most of the work of the Aerodynamics Division is concerned with fundamental problems in fluid motion related to the design and performance of aircraft and guided missiles, though a wide range of airflow problems not related to aircraft is also tackled. Special attention was paid during the year to problems of 'mixed' flows at high subsonic, transonic and supersonic speeds; to the extension of the speed-range covered by the Division's experimental equipment; to schemes which enable aircraft to take off and land vertically or from very short runways; and to the measurement of aerodynamic coefficients for oscillatory motion. For research on hypersonic flow several new wind tunnels that will give various Mach numbers up to 10 and operate over a wide range of stagnation pressures and at high temperatures, in addition to a shock tube, are designed or are being planned. The Division's compressed-air tunnel, stated to be the only equipment of its kind in Britain, has now completed 25 years service, but it is still considered a vital piece of equipment and its utility has been extended recently by improvements and the development of new techniques.

In the Control Mechanisms and Electronics Division, apart from the constructional work on the new automatic computing engine (ACE) and the maintenance of DEUCE, a small group has continued the study of the application of high-speed computers to clerical operations. The report on pay-roll work has been published. The Division has completed prototype equipment for automatically reading and calibrating telemetry records, and transistor circuits are being developed for use in pulse-counting systems. The cæsium resonator in the Electricity Division has been adopted by the Laboratory as its primary standard of frequency. The guaranteed accuracy of the standard frequency transmissions has been quadrupled, and the values of the radiated frequencies are now published with an accuracy of one part in 10^9. To permit a new determination of the absolute ampere, the current balance is being overhauled and fresh measurements of the dimensions of the coils are being made. Significant changes in the diameters have occurred since 1935. This work is closely linked with that on the new standard of inductance, for which measurements on the quartz cylinder are being made in the Metrology Division. A major item of new equipment in the Electrical Division is the million-volt transformer for the high-voltage laboratory.

Research into the properties of the average eye has again been the principal fundamental investigation of the Light Division. The primary standard of luminance was re-established, the final value being 59·7 candelas/cm.^{2}, 0·5 per cent below the value of 60 candelas/cm.^{2} prescribed in the definition of the candela. Further development took place in the making of diffraction gratings and improved methods of photometry were worked out to serve the needs of the electric-lamp industry. The Mathematics Division was able to devote more time to research and considerable effort was devoted to the solution of differential equations, particularly equations of the parabolic type. One result of collaboration with universities was the production of a series of programmes for DEUCE on the solution of crystallographic problems.

The most interesting result reported by the Metallurgy Division is the proof, using radioactive phosphorus, of the existence in certain irons of very thin grain-boundary films rich in phosphorus, which are associated with exceptional weakness and brittleness under suitable conditions. The possibilities of niobium, both as a basis of new alloys and as an alloying addition to other metals, are being studied and the most sensitive methods examined for the determination of very small quantities of impurities in metals. The Metrology Division has developed equipment, using the pneumatic gauging technique, to measure the thickness of thin sheet material to an accuracy of $\pm$ 0·5μ on sheet or foil 25–250μ thick. The value found for the density of mercury at 20° C. by weighing the mercury displacement of a 10-kgm. cube of tungsten carbide is 13·545892 gm./cm.^{3}. The error is estimated to be less than 1 part in 10^6. Preparations are being made for a new absolute determination of gravity in order to improve the accuracy of pressure measurements with the mercury barometer and the precision of determination of the ampere by the current balance, and to enable magnetic fields, for example those involved in the measurement of the gyromagnetic rotation of the proton, to be standardized absolutely. The method to be used for the gravity measurement involves the timing of the free fall of a ball in a vacuum.

The work of the Physics Division has been extremely varied, ranging over heat, acoustics and ultrasonics, high pressures and radiology. The demand for the supply of liquid helium to other laboratories has settled down to about 20 litres per week—rather smaller than originally estimated. In the Heat Section new equipment to apply the radial heat-flow method to the determination of thermal conductivities to temperatures of the order of 1700° C. is being installed and in the Temperature Measurement Section the investigation of the relative merits of the boiling point of sulphur (444·600° C.) and the freezing point of zinc (419·50° C.) as a primary fixed point is continuing. Measurements have been made of the elasticity of tiny single crystals such as sapphire and diamond, and of the elastic constants of single crystals of pure copper, copper–zinc and copper–gallium alloys. The Ship Division reports a delay of five to six months in the putting in hand of resistance and propulsion tests for shipbuilders. The delay is because of an increased demand for tests and because of the introduction of the five-day week in the Laboratory. The investigation of the effect of various structural roughnesses on the behaviour of ships' hulls has yielded some interesting information. For small ships the resistance of an all-riveted hull can be as much as 10 per cent greater than for an all-welded hull, and for larger and faster ships it may be as much as 25 per cent greater.

Finally, the annual report, which is presented in an attractive cover and is illustrated, concludes with a report of the Test House, indicating the significant increase in the variety of precision instruments submitted for test to the Laboratory.

S. Weintroub

UNIVERSITIES OF LATIN AMERICA

Although the nations of Latin America are of recent growth they inherit an ancient university tradition. Almost as soon as the Spaniards had completed the first of their settlements in La Española (Hispaniola), a Bull issued by Pope Paul III in 1538 transformed the island's Dominican college into the University of St. Thomas Aquinas. Not long after Hermán Cortés's conquest of Mexico and Pizarro's extinction of the Inca Empire in Peru, the Emperor Charles V established universities in his two new American kingdoms: Mexico City held its first classes in 1553 and San Marcos was functioning actively by 1578. The oldest Latin American universities are coeval with the oldest Scottish universities and antedate many famous European centres of higher learning. An account of them has been given by J. C. J. Metford of the University of Bristol (*The Universities Review*, 30, No. 1, October 1957).

As Spanish settlements expanded all over America, the Dominicans, Jesuits and Franciscans founded schools attached to their monasteries. Before the sixteenth century had ended, their *colegios* were to be found in places so far apart as Antigua, on the isthmus of Central America, Chuquisaca, in the lofty silver mining region of Bolivia, and Córdoba, in the foothills of the Andes. There, and in many other centres, courses in the arts, grammar, philosophy and theology were being delivered almost as soon as the townships were marked out in their characteristic grid-iron pattern. The *colegios* grew with the towns, and, in the eighteenth century, many *colegios* were granted the status of Royal and Pontifical universities. By the end of the colonial period, there was scarcely a region of importance in the Spanish American Empire without its university, or college, where advanced studies could be pursued.

As in Europe, the universities and colleges of Spanish America had their periods of brilliance and their times of decline, but, on the whole, they did not compare unfavourably with universities in the Old World. Although dependent upon endowments, or grants from royal, vice-regal or ecclesiastical treasuries, they enjoyed a reasonable measure of independence in the management of their internal affairs and in the granting of degrees. Their chief function was to train aspirants to the priesthood or candidates for higher theological degrees. Science was not wholly neglected: mathematics and astronomy were studied, and much work was accomplished on the curative plants and herbs known to the Indians. From an early date in Mexico City and Lima, there were chairs for the study of Indian languages, but the intention was to use this knowledge in the evangelization of the aborigines. University teachers were drawn chiefly from the ranks of the Dominicans and the Jesuits, but, in the eighteenth century, lay professors were not unknown.

Independence from Spain and Portugal caused little change in the social structure of the former American colonies, except that the wealthy *criollo* minority succeeded to positions which were previously the perquisites of peninsular Spaniards and Portuguese. Much lip-service was paid to the catchwords of freedom, equality and the pursuit of happiness, but little was done towards the realization of these ideals, except, to some extent, in the field of education. Nurtured in French, North American and British radical traditions, the fathers of the revolution believed sincerely in the power of education to spread enlightenment. The University of Buenos Aires was founded in 1821 by men associated with Rivadavia, who had corresponded with Jeremy Bentham. Bolívar founded the Universities of Cartagena, in Columbia and Trufillo, in Peru. His lieutenant, General Santander, established the University of Cauca. Political upheavals, anarchy, the rise of dictators and empty treasuries eventually terminated these ambitious schemes. Despite men like Andrés Bello, in Columbia and Chile, Sarmiento and Alberdi, in Argentina, and the Emperor Don Pedro II, in Brazil, little was accomplished, so far as universities were concerned, until the second half of the nineteenth century.

By that time, some of the major nations—Argentina, Brazil and Chile—had stabilized their domestic affairs and had grown in wealth and importance. The need, the means and the will to improve educational facilities followed. Institutions of higher learning and universities were created in the principal States. In Bolivia and Brazil, the tendency was to establish degree-granting faculties instead of universities.

The most significant event in the history of the modern universities was the reform movement which began in Cordoba, Argentina, in 1918. Essentially, it was the work of young men, who looked upon themselves as the harbingers of the new Latin America which would be fundamentally American, freed from dependence on Europe and purged of inherent abuses. They were all greatly influenced by the iconoclasm of the Spanish writer and thinker, Miguel de Unamuno. Much of their educational outlook derived from the works of Ortega y Gasset. Practical measures were embodied in Argentine law between 1919 and 1922. From Argentina, the reform movement spread to many other Latin American countries and influenced legislation on university government especially in Bolivia, Colombia and Cuba.

The Second World War brought far-reaching changes in the life of Latin America which were not without their impact on the growth of universities. High prices from the belligerents for raw materials meant an astronomical increase in national wealth. At the same time, attempts were made to create locally industries for the production of commodities which had hitherto been imported. To fulfil these national and industrial ambitions, a supply of university-trained men would be needed. With this in mind, some of the more perspicacious governments arranged that part of the newly acquired wealth should be diverted either to the improvement of existing institutions or to the creation of new universities. The best examples of this new policy are the superlative modern buildings constructed for the University of São Paulo in the midst of Brazil's rapidly growing industrial area.

To-day, there is no country in Latin America without at least one university. There are eighty-eight throughout the region, although some have only two or three faculties and some are little more than a loose confederation of otherwise independent faculties. The largest institutions, with more than ten thousand students each, are the National University of Mexico and the Universities of Havana, Buenos Aires and La Plata. Argentina has at least three other universities with between five and ten thousand students each, and Uruguay, Chile and Peru one university each of comparable size.

Nearly all of them have important features in common—they are part of the State system of education, their powers and functions are carefully prescribed by law, and they are mostly subject to direct interference by the president of the nation, the ministry of education, or some governmental equivalent. The exceptions are the so-called *universidades particulares*, or private universities, of which the University of Concepcion, Chile, is the best secular example. The majority are Roman Catholic (for example, Santiago de Chile, Lima, Bogota), either concerned with the education of priests or founded to preserve the faithful from the militant secularism characterizing some of the State universities, which were controlled by positivists, humanists and others hostile to clerical influences in education. A certain measure of government control is nevertheless exercised through the State recognition of their degrees.

State control is also clearly seen in finance. Universities generally are dependent on the State for practically three-quarters of their annual income.

As in Spain and Portugal, the teacher in Latin America, whether at school or university level, enjoys a degree of respect, almost veneration, unknown to his counterparts in Anglo-Saxon countries, but the esteem in which he is held is in inverse proportion to the rewards of his profession. University teaching therefore becomes a part-time occupation, as few men of standing would be content to exist on a meagre university salary. Most teachers are professional men—lawyers, doctors, engineers, or even novelists or journalists—who spare a few hours a day for their classes, or perhaps leave them to a trusted assistant.

Most students come from the urban conglomerations around the university and live at home or with relatives. Newly planned campuses now include *residencias*, but these are exceptional. Usually, the student has some part-time employment, often connected with the profession for which he is preparing himself, and, towards the end of his course, he may be married, with a young family of his own. Lack of continuity often characterizes a student's career, as his circumstances or predilections change, and he may remain a student for a surprisingly long time. This, in some measure, explains the high enrolment figures announced by some institutions. The University of Mexico City thus claims more than 22,000 students, a high proportion of whom are unlikely to be full-time.

OVERSEAS SERVICE IN BRITISH COLONIAL TERRITORIES

THE Overseas Service Bill, which received an unopposed second reading in the House of Commons on January 21, is an enabling Bill to implement the policy outlined in the White Paper of May 1956 on the Overseas Civil Service. In moving the second reading, the Secretary of State for the Colonies, Mr. A. Lennox-Boyd, said that formidable difficulties had been encountered in the proposed policy for a central register and pool, particularly in guaranteeing a continuing career, that is, a succession of jobs of ascending importance and level of responsibility for an officer recruited into the central pool initially for a particular job in a particular territory. On March 26, 1957, the Lord Privy Seal had announced that the creation of a pool of administrative and technical officers must await evidence of substantial demand for their services and that regular employment for them could be foreseen for several years. Meanwhile, Clauses 2 and 3 of the Bill provided for the making of Orders to govern pensions earned while in the Overseas Service and for the preservation of pension rights already acquired. When the Bill became law the Governments of the Colonies would be asked to enact comparable legislation. Clause 4 contained special provisions relating to police officers and Clause 6 covered the appointment of officers to a wide variety of public services under overseas Governments, municipal or local authorities or public corporations or to any Federal Government or outside authority such as the East African High Commission.

Mr. Lennox Boyd said that at the constitutional conference last June he had signed agreements for special lists with the four Nigerian Governments but so far only about 120 out of the 2,000 eligible pensionable officers in the service of these Governments had applied to join. Sir John Martin was in Nigeria examining the position, and the application of the special list procedure was the subject of current negotiations with the Government of Malaya. In conclusion, Mr. Lennox Boyd said that, in 1957, 1,689 officers were selected for appointment to the administrative or professional branches compared with 1,467 in 1956, and of these, 284, mostly on contract, were to Nigeria. Mr. Lennox-Boyd and other speakers paid warm tribute to the work, the loyalty, the efficiency, the integrity and the quality of the Overseas Service. In replying to the debate, he added that, although there was a substantial gap between demand and supply, we were recruiting at four times the pre-war rate over the whole field. At the end of 1957 there were 130 vacancies in administration and 1,384 in all branches, compared with 170 and 1,456, respectively, in 1956, and the proportion of vacancies to the total number of overseas officers in the service was now about 7 per cent. In Ghana, about 400 officers, or 50 per cent of those entitled to compensation, had retired since July 1955. Mr. Lennox-Boyd defended the Government's policy in regard to compensation as holding a reasonable balance between justice to those officers who wished to retire and the duty to try to induce them to stay. He explained that the recruitment and employment of experts under the technical co-operation scheme were covered by administrative action and it was not intended to change this procedure. Foreign Office appointments to South East Asia Treaty Organization posts were normally filled by secondment, but if a person from the Overseas Civil Service were recruited the provisions of the Bill could be applied if necessary.

MANAGEMENT TRAINING

IN the fourth Graham Clark Lecture to the Institution of Civil Engineers on December 17, on "The Engineer and Management", Sir Ewart Smith said that while science and its practical applications through engineering and chemical technology had shown that we were potentially able to meet any standard of national welfare mankind could desire, subject to some limit to world population with regard to natural resources, the rate of advance in science and technology was not being matched by progress in our ability to control and manage. Sir Ewart suggested that this might be due to our neglect in human affairs and organization of the guiding principles of simplicity, symmetry (or balance) and continuity. More research, better analysis and far better teaching in management subjects were needed, and it did not seem to be appreciated that the very growth of complexity and specialization increased the need to train with great care those who will have the responsibility of training the specialists.

Discussing selection and training for management, Sir Ewart emphasized the importance of regular, multiple and independent assessments of ability to men and management alike. Far too much weight was often placed on written examinations during the period of formal training, and in industry there was usually little systematic study of people to assess their potential and the best lines for their development. A main responsibility of the highest management should be to pick its own potential successors and to train them with the utmost care, from the early years of service, and Sir Ewart welcomed recent discussion on the general content of educational courses; it should be a question of how science and the humanities could be reunited in everyone who claimed to be reasonably educated, and he thought that the main change had to take place in the schools rather than in the universities. It was a mistake to think that three years was still an adequate period for a full university course in scientific and technological subjects, and Britain was almost unique among the great nations in its failure to make the changes in this respect which modern conditions demanded. More time should be spent in teaching people how to use knowledge, and where they could find it in codified form when they required it in their working life. Good education, moreover, depended primarily on good teachers and relatively little on buildings and equipment. Emphasizing the importance of the engineer in management, Sir Ewart suggested that the main reason for our failure to utilize their services here has been the present acute shortage of technologists, which tends to confine them to specialist work. There was no reason to suppose that the incidence of natural ability, initiative and enthusiasm had diminished, but for Britain to attain her full economic strength the engineer must play a full part in leadership and in developing the most effective forms of organization and methods of management for a changing world.

THE LINNAEUS TRADITION AND OUR TIME

IN his presidential address to the Swedish Academy on December 20, Mr. Dag Hammarskjöld took as his subject "The Linnaeus Tradition and our Time". He considered Linnaeus's contribution towards the development of values which it is the task of the Academy to safeguard. Freshness and precision, enthusiasm without lyricism, an instinctive eye for meaning and causality raised the great travel accounts and his other Swedish writings far above the criticism he himself foresaw, and enriched his country's literature by values as essential to our emotions as the Nature they mirror. Nevertheless, his style would scarcely have found its freshness had he not been guided by his sense for the striking and for the unexpected associations of humour. Linnaeus's Swedish works are perhaps read to an increasing extent even outside the circle of experts.

The relationship of a nation—and a generation—to older literature tells something about the continuity of spiritual life. Outside the limits of *belles lettres*, the works of Linnaeus occupy a place of their own in Sweden, whereas other books which have much to offer are neglected.

One possible reason for the estrangement from the past is disquieting. In a mass culture, where publicity, working in the interest of sales, is constantly harping on the idea that the latest must be best, books are often relegated to the ranks of disposable and rapidly ageing consumer goods, which may lead to an industrialization of literature. The risk is enhanced when, at the same time, the position of the written work is becoming more precarious by reason of new forms of expression and communication —films, radio, television.

We are faced with the question of intellectual climate and what determines it. The present has given unusual weight to material progress ; it is also influenced by political factors. Europe has lost much of the powerful position she occupied for centuries and a wave of nationalism has swept the continents. If she understands how to maintain and develop the values which are the foundation of her spiritual greatness she can still maintain a place worthy of her traditions.

When Linnaeus received tempting offers to remain in Holland he declined because "a higher urge pulled him towards his Fatherland". The scholar, however, knew no national frontiers. He was a European, and, as a European, a citizen of the world. Much has changed, but it is still possible to balance and reconcile home and world, heritage and task, in this manner. This can provide an answer to even larger problems than those of the individual.

STRESS IN HYPOTHERMIA

By H. S. SAMULI SARAJAS, PAULA NYHOLM and PAAVO SUOMALAINEN
Zoological Institute, University of Helsinki

THE induction of hypothermia in homoiotherms consists essentially in a suppression of the thermoregulatory defence by anæsthetics followed by intense cooling of the body. While cold stimulus in unanæsthetized homoiotherms inevitably evokes a general stress response[1], there is a considerable degree of controversy as to whether or not hypothermia involves stress. Changes in the amount and distribution of the adrenal cortical lipids suggestive of stress have been reported to result from hypothermia of a few hours duration in dogs[2]. On the other hand, the recent observations that the adrenal venous blood output of 17-hydroxycorticoids is decreased in hypothermic subjects[3,4], while the peripheral serum-levels[5] and urinary excretion[6] of the adrenal cortical steroids remain substantially unaltered, have been interpreted as indicating that there is no actual stress response to hypothermia.

The present study was undertaken to elucidate the stress response in dogs subjected to graded hypothermia, with or without subsequent rewarming. Thirty-five dogs, apparently healthy and 'unstressed' individuals, were anæsthetized with pentobarbitone, either alone or in combination with diethyl ether, or nitrous oxide–oxygen and D-tubocurarine. Some of the dogs were subjected to minor vascular surgical procedures prior to cooling. The dogs were cooled in an ice bath (4–8° C.). With a few exceptions, pulmonary ventilation was assisted during cooling and hypothermia. Rewarming was accomplished in a warm bath (about 40° C.). Changes in the amount and distribution of the sudanophilic adrenal cortical lipids and in the white blood picture were used as methods of computing the stress response.

In all but four of these thirty-five dogs there was evidence suggestive of stress response, so far as could be judged from the adrenal cortical lipid patterns. In eight dogs there was lipid depletion particularly in the zona fasciculata and zona reticularis, which is indicative of the alarm reaction[1]. In twelve dogs an increase of lipids throughout the whole adrenal cortex characteristic of the stage of resistance[1] was apparent. In ten dogs the adrenal cortical lipid patterns were suggestive of transitory stages between the normal state and the stage of alarm reaction, on one hand, and those between the alarm reaction and the stage of resistance, on the other. In one dog, signs of alarm reaction bordering on the stage of exhaustion were apparent.

The dogs that did not show an adrenal cortical response had been anæsthetized with pentobarbitone alone and then cooled, without assisting ventilation, until death ensued (at 20·3–25·3° C.) after 2–4 hr. However, all the other dogs anæsthetized with pentobarbitone in combination with ether, or nitrous oxide–oxygen and curare, and then cooled until death (at 14·0–33·5° C.) within the same, a somewhat longer, or an even shorter period, showed a definite adrenal cortical response varying from an early alarm reaction to an early stage of exhaustion. The actual degree of cortical response did not appear to be influenced by variables in the mode of respiration. Nor could any clear-cut aggravation of the response be detected in the dogs that had been subjected to minor vascular surgery prior to cooling. The dogs that had been anæsthetized with pentobarbitone in combination with nitrous oxide–oxygen and curare showed evidence of a progression of the cortical response in accord with an increase in the cooling period, whereas in the dogs in which ether had been used as a supplementary anæsthetic such a correlation was less evident. In one series of experiments the dogs were kept for 4 hr. near body temperatures of 22·0° and 27·0° C. and then killed. In another series the dogs were kept for 2–6 hr. at a body temperature of about 22·0° C., rewarmed and then killed at the termination of rewarming, or 3–7 days thereafter. Pentobarbitone supplemented with ether had been used for anæsthesia in these experiments. The terminal pattern of the adrenal cortical lipids in all these experiments was indicative of stress. Surprisingly, however, the cortical responses were of the same variable degree as those in the acute experiments ending in death.

The behaviour of the white blood picture during cooling, with or without subsequent rewarming, was followed in twelve dogs. Cooling resulted in a progressive fall in the total leucocyte count, averaging from 12,870 per mm.^{3} (at 37·5° C.) to 4,508 per mm.^{3} (at 21·0° C.) ; but the relative counts of eosinophils, lymphocytes and other types of leucocytes remained substantially unaltered. In the stable period of hypothermia (at about 22·0° C.) lasting up to 6 hr., the white blood picture remained essentially stationary. Accordingly, during cooling the counts of eosinophils and lymphocytes did fall in proportion to the drop in the total leucocyte count. Since, on the other hand, no further changes could be found in the stable period of hypothermia, it is doubtful whether these hæmatological changes could be properly interpreted to imply that stress was present. Nevertheless, in the same dogs, after cooling periods of varying duration, the stress response became clearly demonstrable by the adrenal cortical lipid assay. On rewarming, the white blood picture initially showed a trend to normalization. In the late rewarming period (at 35·0° C.), however, neutrophilic leucocytosis (averaging 15,400 per mm.^{3}) with both relative and absolute eosinopænia and lymphopænia became apparent. These hæmatological changes ensuing in the late rewarming period may be regarded as strictly indicative of stress[1]. The same dogs, when killed at the termination of rewarming, showed a definite stress response as estimated from the adrenal cortical lipid patterns.

Summarizing, the present results, supported by some earlier observations[2], strongly suggest that the induction of hypothermia evokes a general stress response. It became evident, however, that this response is not inevitable, but is largely influenced by the anæsthetics used to assist the induction of hypothermia. Barbiturates, for example, appeared to inhibit the stress response to cooling. The stress manifestations were particularly evident at the termination of rewarming and persisted for several days thereafter.

The recent claims that hypothermia does not involve stress are based on observations that the adrenal venous blood output of the adrenal cortical steroids is decreased by hypothermia[3,4], while their peripheral serum-levels[5] and urinary excretion[6] remain unchanged. In view of the fact that hypothermia is known to be accompanied by profound changes in metabolic activity, circulatory dynamics and renal function, it may be questioned whether the assays mentioned afford a true picture of the situation in the particular experimental conditions of hypothermia. It may be recalled that even in the present experiments, in which the experimental variables were the same as in the aforementioned studies, there was no definite hæmatological evidence of stress during cooling and hypothermia, although at the same time the stress response was clearly demonstrable by the adrenal cortical lipid assay. Moreover, it has been found that after rewarming, when the metabolic, circulatory and other physiological functions are restored, a rise may occur in the adrenal venous blood output[4] and peripheral serum-levels[5] of the adrenal cortical steroids. Finally, the pathological changes found in the present[7,8] and later[2] experiments on hypothermia are essentially similar to those seen in states of acute severe stress of varying origin[1,9].

The present results will be described and discussed in detail elsewhere.

EFFECT ON RADIOSENSITIVITY OF INERT GASES

Effect of Inert Gases on Oxygen-dependent Radiosensitivity

LIKE many other tissues, the meristem of the main root of the broad bean seedling (*Vicia faba*) is two to three times more sensitive to X-rays in the presence of oxygen than in its absence. In the experiments to be described, the measure of radiosensitivity is the reduction in growth-rate of the root, which is believed to be due predominantly to death of the cell following upon chromosome damage. There is no qualitative difference in the damage caused by irradiation in the presence or in the absence of oxygen, the oxygenated condition acting as a simple multiplying factor upon dose[1].

We have found that if inert gases are added to the air in which bean roots are exposed to X-rays, the sensitivity of the roots decreases until at sufficient concentration of the inert gas it reaches the anoxic level. We have not observed any effect of the gases on the radiosensitivity of roots in the absence of oxygen. Similar results have been obtained with cells of the Ehrlich ascites tumour of the mouse irradiated *in vitro*. We conclude that inert gases at high concentration can displace oxygen from sites within cells at which oxygen molecules can increase radiosensitivity, and that this phenomenon occurs in cells of widely different kinds.

Bean roots. The pressure vessel and the procedure used in the treatment of bean roots, and some of the results, have been described[2]. 190-kV. X-rays at 6 m.amp. were used at a dose-rate of 1·84 r./sec. Filtration was 1 mm. copper, 0·5 mm. aluminium and 3 mm. mild steel. Gas pressures up to 120 atm. had at most only slight and transient effects on the roots, and did not affect radiosensitivity if applied before or after exposure to radiation. Hydrostatic pressure of 105 atm. was also not in itself damaging, and was without effect on radiosensitivity, as observed for yeast cells by Burns[3].

Irradiated roots showed a reduced growth-rate which reached a minimum six to nine days after exposure. The minimum growth-rate, compared with appropriate controls, was taken as a measure of radiation damage[4]. To provide an estimate of relative sensitivity in different gases, we established a dose-effect curve for irradiation in air at 1 atm. The curve was found to be linear over the useful range, that is, 40–150 r., and was described by the equation:

$$\text{minimum growth rate} = 167 - 1{\cdot}49 \times \text{dose in röntgens}$$

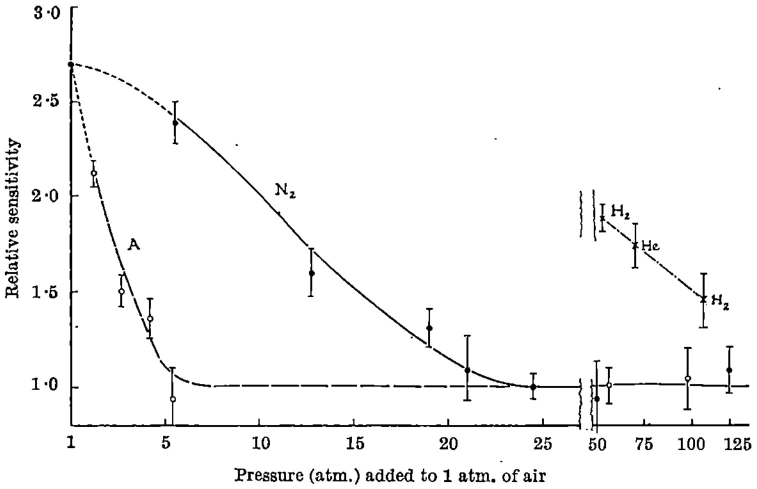

Fig. 1. X-ray sensitivity of bean roots irradiated in 1 atm. air plus other gases. Abscissæ: pressure of added gas in atmospheres. Ordinates: relative radiosensitivity

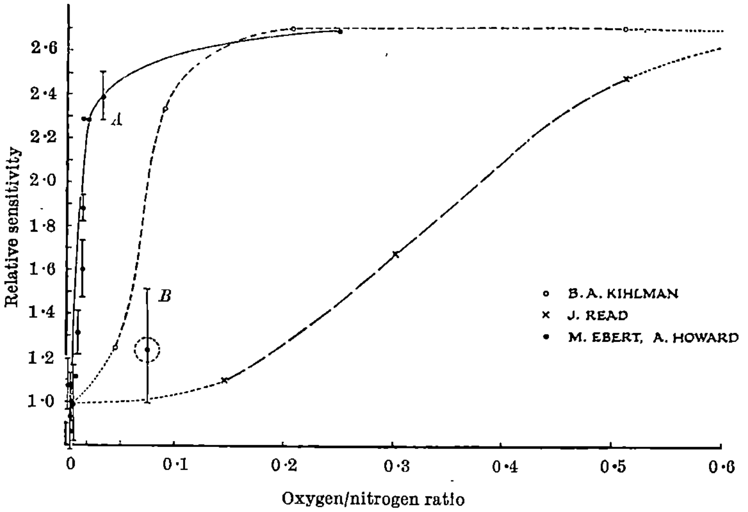

Fig. 2. Radiosensitivity of bean roots as a function of the ratio of oxygen to nitrogen. O, B. A. Kihlman (1955); ×, J. Read (1952); *A*, present observations at 0·2 atm. oxygen; ●, present observations at 1 or 2 atm. oxygen; *B*, present observations at 0·07 atm. oxygen

From this equation we calculated the dose in air, D_A, required to give an effect equal to that produced by dose D in any set of experimental conditions, and the ratio D_A/D gave the sensitivity relative to that in air. In order to express this in terms of the anoxic sensitivity, the ratio D_A/D was multiplied by the factor 2·69, since the effectiveness of a given dose was observed to be 2·69 times smaller in anoxic conditions (or in air plus high pressures of nitrogen or argon) than in air, in agreement with results of Read[1]. Thus 'relative sensitivity' is defined as $D_A/D \times 2{\cdot}69$. The standard errors of the relative sensitivity values shown in the accompanying figures were estimated from the standard errors (in terms of dose) of the experimental observations, and the overall error (± 2·64r.) in the air dose-effect curve.

We have studied the action of hydrogen, helium, nitrogen, argon, krypton and xenon, the effect of all of which is qualitatively the same. In Fig. 1, relative sensitivity is plotted against the pressure of gas added to 1 atm. of air. It can be seen that argon at 5 atm. reduces sensitivity to the anoxic level, whereas nitrogen must be present at 21 atm. to be equally effective. Hydrogen and helium are much less effective. To give a comparison of the effectiveness of the different gases, Table 1 shows the pressure required to reduce the relative sensitivity to 1·85, that is, the part of the effect dependent upon oxygen to one half. The values were derived by linear interpolation and are approximate.

When relative sensitivity is plotted against the ratio of the partial pressures of oxygen to nitrogen (Fig. 2), radiosensitivities for all treatments in which the partial pressure of oxygen (pO_2) was 0·2 atm. or more lie on a smooth curve. For one observation made at $pO_2 = 0{\cdot}07$ atm. (total pressure 1 atm.), however, the relative radiosensitivity did not fall on this curve but was much lower. These results suggest an adsorption phenomenon in which nitrogen displaces oxygen from a specific site. The second observation demonstrates the limiting condition in which the partial pressure of oxygen is small compared with that required to saturate the adsorbing site.

In Fig. 2 are plotted also the results obtained by Kihlman[5] for chromosome aberrations induced in bean roots by X-rays at various oxygen tensions: the values have been scaled down to a total oxygen effect of 2·69 for the purpose of this comparison. Kihlman bubbled through the vessel before and during irradiation a stream of gas of the desired oxygen/nitrogen mixture at 1 atm. Our observation at $pO_2 = 0{\cdot}07$ atm. gave a value close to Kihlman's curve; this is less steep than ours at $pO_2 = 0{\cdot}2$, and more steep than that obtained by Read[1], who irradiated roots in closed vessels in which the oxygen tension had been previously adjusted to a desired level. Read's paper contains a discussion of the extent to which the water surrounding the roots must have become deoxygenated through oxygen consumption before and during irradiation. We think that the differences between the three sets of observations shown in Fig. 2 are satisfactorily explained by differences in the amount of oxygen present.

These considerations indicate that radiosensitivity is a function of oxygen/nitrogen ratio only when

Table 1. EFFECTIVENESS OF VARIOUS GASES IN REDUCING THE OXYGEN-DEPENDENT RADIOSENSITIVITY OF *Vicia faba* ROOTS

Gas	Pressure in atm. for 50 per cent effect	Partition coefficient lipid/water (ref. 12)
Helium	55	1·7 (37° C.)
Hydrogen	55	2·3 (22° C.)
Nitrogen	12·5	3·5 (22° C.)
Argon	2	4·0 (22° C.)
Krypton	2	7·5 (22° C.)
Xenon	1·1	14·5 (22° C.)

sufficient oxygen is present throughout the root to confer full sensitivity, and that oxygen-dependent sensitivity is determined by the absolute amount of oxygen present in the cell or some part of it. This amount can be reduced by lowering the oxygen tension at the cell, or by displacing the oxygen from a site within the cell by a sufficient concentration of another gas.

Oxygen is supplied to the root tip by diffusion through the gas spaces in the root and through the liquid layers surrounding the root and the meristematic cells. Diffusion of gases through the liquid phase is not appreciably influenced by pressures of a few hundred atmospheres. On the other hand, the diffusion-rate of one gas through another is inversely proportional to the total pressure. The calculated diffusion constants of oxygen at 0·2 atm. differ according to the identity of the other gas present: these differences are not, however, in the same sequence as that of the effectiveness of other gases in reducing oxygen-dependent sensitivity[6]. It is thus very unlikely that the inert gases act by reducing the rate at which oxygen moves through liquid or gaseous intercellular spaces in the root. It appears that they must act at the cellular level.

Tumour cells of the mouse. To test this point and to extend our observations to other material, we carried out experiments with suspensions of mouse Ehrlich ascites tumour cells. Six days after mice had been inoculated, ascitic fluid was collected and stored in crushed ice. Samples were irradiated as a layer 2 mm. deep in flat 'Polythene' dishes within a pressure vessel, after being exposed to the chosen gas mixture for 20 min. with stirring. Gas equilibration and irradiation were carried out at 0–2° C. to reduce the oxygen consumption of the cells and so avoid the depletion of oxygen which would otherwise occur in the deeper cell layers during irradiation. (In a control experiment we measured the time required by washed ascites cell suspensions in a potassium phosphate buffer (*p*H 7·2) to reduce added hæmoglobin, and found that the utilization of oxygen at 0°–2° C. is at least twenty times slower than at 20° C.) The irradiated cells were inoculated into fresh hosts (0·2 ml. intraperitoneally), the hosts were killed after 18 hr. and the tumour cells fixed in acetic acid-ethanol (1 : 3 v/v). Four different doses of X-rays were given with each gas mixture investigated. The fraction of normal anaphases was an exponential function of the dose. The exponent was determined from at least six samples of 200–300 anaphases each. The best fit for the exponential function was calculated using the formula given by Lea and Catcheside[7]. The ratio of the doses required to reduce the fraction of normal anaphases to the arbitrary value of $10^{-1/2}$ was used to calculate the radiosensitivity under different treatments. The results (Table 2) showed that when cells were irradiated in the presence of a partial pressure of 0·2 atm. oxygen, the oxygen-dependent part of the radiosensitivity was reduced to 54 per cent by the addition of 110 atm. of hydrogen, and to 38 per cent by 110 atm. of nitrogen; with 21 atm. of argon the radiosensitivity was the same as that of cells irradiated in anoxic conditions.

Bacteria. A preliminary experiment with *Shigella flexneri Y6R* (carried out in collaboration with Miss Tikvah Alper) showed that argon was more effective than nitrogen in reducing the oxygen-dependent part of the radiosensitivity of this organism. It was, however, necessary to use 0·01 atm. partial pressure of oxygen (sufficient to confer 95 per cent of the oxygen-dependent sensitivity[8]) and much higher ratios of argon or nitrogen to oxygen than were required to give the same effect in bean roots.

Table 2. EFFECT OF GASES ON THE RADIOSENSITIVITY OF EHRLICH ASCITES TUMOUR CELLS

Experiment	Gas mixture pressure in atm.	Dose in r. to reduce normal anaphases to 31·6 per cent	Relative sensitivity
I	No air + 93 nitrogen	768 ± 32	1·0 ± 0·04
I	No air + 100 hydrogen	798 ± 36	0·96 ± 0·06
I	1 air + 110 hydrogen	418 ± 12	1·84 ± 0·05
I	1 air + 110 nitrogen	595 ± 27	1·29 ± 0·06
I	1 air	225 ± 15	3·40 ± 0·08
II	No air + 100 nitrogen	680 ± 18	1·00 ± 0·03
II	1 air + 21 argon	705 ± 30	0·97 ± 0·05

Effect on oxygen consumption. It was of interest to establish whether the effect of inert gases could be explained either by an increased rate of utilization of oxygen or by interference with the free passage of oxygen through the cell membrane. We therefore examined the rate of utilization of oxygen by Ehrlich ascites or by bacterial cells when exposed to 1 atm. of air plus 20 atm. of either nitrogen or argon. Washed suspensions of cells, at *p*H 7·5, were put into two identical 'Perspex' pressure vessels, with hæmoglobin as an oxygen indicator. One vessel served as control, and to the other was added either 20 atm. of nitrogen or 20 atm. of argon, and both vessels were shaken gently. The time taken for reduction of the hæmoglobin, as observed by hand spectroscope, afforded an estimate of the rate of utilization of oxygen by the cells to an accuracy of approximately ± 15 per cent. It was found for both Ehrlich ascites tumour cells and for *Shigella* that the rate of utilization of oxygen was influenced neither by nitrogen nor by argon at pressures at which these gases affected oxygen-dependent radiosensitivity. It was concluded that oxygen must have been present inside the cells under our experimental conditions, and that the protective effect of the inert gases was not due to a greatly enhanced utilization of oxygen. The evidence therefore suggests very strongly that the inert gases act intracellularly.

Conclusion. We may postulate that specific and finite sites exist within the cell at which oxygen must be present to confer oxygen-dependent sensitivity, and that inert gases can displace oxygen from these sites. That oxygen and the other gases compete for the same sites is indicated by the experimental finding with bean roots that sensitivity is governed by the ratio of oxygen to the other gas provided that the partial pressure of oxygen is sufficient to guarantee saturation of the site. Furthermore, when the oxygen effect was blocked by one gas (20 atm. of nitrogen), the addition of an excess of another protecting gas (100 atm. of argon) did not further reduce the radiosensitivity. This result suggests one mechanism for both gases, and is consistent with a displacement adsorption phenomenon at a defined site.

Some inert gases are known to be anæsthetic, and many years ago it was postulated that this property is related to their lipid-water partition coefficients[9]. Table 1 shows that a parallel exists also between these coefficients and the effectiveness of the gases in reducing radiosensitivity in bean roots. The apparent discrepancy between the very different effectiveness of nitrogen and argon and their rather similar partition coefficients may perhaps be explained by the fact that argon is approximately twice as soluble as nitrogen both in water and in lipid.

The relationship with anæsthetic effect led us to test the commonly used anæsthetic gas cyclopropane: we found that, at 2 atm. added to 1 atm. of air, it blocked the oxygen-dependent sensitivity of bean roots by about 50 per cent. Cyclopropane is 34·4 times more soluble[10] in olive oil than in water at 37° C.

The parallel shown in Table 1 suggests that the site from which oxygen is displaced may be associated with some lipid-like material in the cell. We know from the unchanged rate of utilization of oxygen under 20 atm. of nitrogen and argon that the site is unlikely to be one of the main cytoplasmic organelles which utilize oxygen. Read has shown (below) that the damage caused in bean roots by 8-ethoxycaffeine, which is known to be dependent on an intact respiratory mechanism[11], is not influenced by argon; this is a further indication that the inert gases do not interfere with this mechanism. The site of action of inert gases may be a lipid-water interface or an area or volume in the lipid fraction of the cell. Since the type of radiation damage which we have been measuring is expressed in the nucleus, and is believed to be the result of energy absorbed there, the site may well be within the nucleus or associated with the nuclear membrane.

We wish to thank Mr. Paul Murfin for his technical help throughout these experiments.

Effect of a Combined Treatment with 8-Ethoxycaffeine and Argon on the Roots of *Vicia faba*

IF roots of *Vicia faba* are irradiated with X-rays when in the normal state of aeration, they are much more sensitive than they are when no oxygen is present. To produce the same damage in the absence of oxygen we must increase the dose by a factor[1] of almost 3. Ebert, Hornsey and Howard have shown (preceding communication) that if a sufficiently large pressure of an inert gas is added to the normal atmosphere in which the roots are irradiated, the damage corresponds to the anærobic sensitivity, although the normal amount of oxygen is present in the gas phase.

The influence of oxygen on the X-ray sensitivity of the roots has a parallel in its influence on their sensitivity to 8-ethoxycaffeine. Kihlman[2] first showed that if *Allium* roots were immersed in an ærated 8-ethoxycaffeine solution for a few hours, chromosome aberrations were produced, but if the solution was free from oxygen there was virtually none. Later[3] he obtained the same result with *Vicia faba* roots. Read and Kihlman[4] then showed that a marked reduction in growth also occurred after a treatment in an ærated solution at 10° C., but if the solution was free from oxygen there was no detectable effect. In these cases, therefore, the influence of oxygen is more marked than when X-rays are used since the reduction is to zero instead of to approximately one-third.

The question naturally arises whether an added pressure of one of the inert gases will abolish the influence of oxygen on the action of 8-ethoxycaffeine, as it does in the case of X-rays. This has been tested in the same high-pressure chamber as was used by Ebert, Hornsey and Howard. It was arranged vertically with the top cover removed. Into it 200 c.c. of 7×10^{-3} *M* 8-ethoxycaffeine solution chilled to near 0° C. was poured, and a group of nine roots was put into the top end so that they did not reach to the level of the solution. The top cover was bolted on and 5 atm. pressure of argon was slowly added to the normal atmosphere in the chamber. The chamber was then placed in a rocking cradle immersed in a trough of water kept at 10° C., and the treatment was commenced by tipping it so that the solution flooded over the roots on its way to the lower end. The tipping was continued at intervals of a minute so that the roots were alternately wetted by the solution and exposed to the gas pressure. After four hours the chamber was removed with the solution drained to the end remote from the roots. The pressure was slowly released, the end cover removed, and the roots extracted. They were rinsed under the cold tap and returned to the culture tank.

Other groups of roots were exposed in a similar manner: (*a*) to 200 c.c. of the same solution without the addition of the argon pressure; (*b*) to 200 c.c. of tap water with the addition of 5 atm. pressure of argon, and (*c*) to 200 c.c. of water without the argon pressure.

The mean growth-rates of these groups of roots have been expressed as percentages of the mean growth-rate of a similar untreated group which co-existed in the culture tank. They are plotted in Fig. 1 against time before and after treatment, which occurred at time zero on the abscissa scale. Roots exposed in water without added argon showed a check in growth only on the day of treatment, due partly to the handling and partly to the four hours at low temperature (10° C.). Roots exposed to the 5 atm. pressure of argon while intermittently flooded with water were more affected, but they had recovered their normal growth-rate after 3–4 days. Ebert, Hornsey and Howard subjected their roots to pressure for periods of only 15–30 min. compared with 4 hr. here, so that it is understandable that they observed no harmful effect unless X-rays were also used. On both occasions when the ethoxycaffeine solution was used the growth-rate curve was of the type already found by Read and Kihlman[4] and the minimum value was about the same as they measured after 4 hr. immersion in 7×10^{-3} *M* solution at 10° C. The two curves, one obtained with added argon and the other without it, do not differ appreciably, and

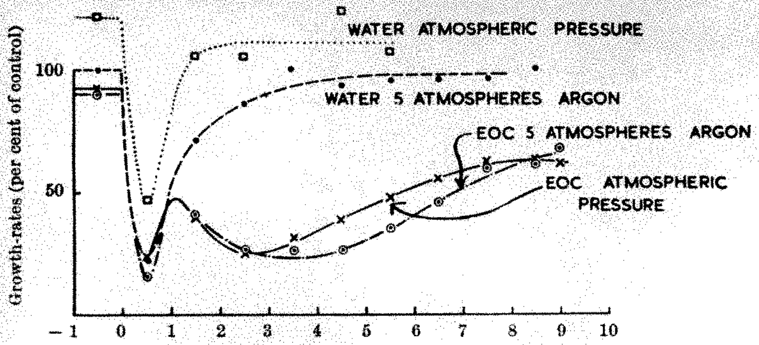

Fig. 1. Ethoxycaffeine and 5 atm. argon (4 hr.)

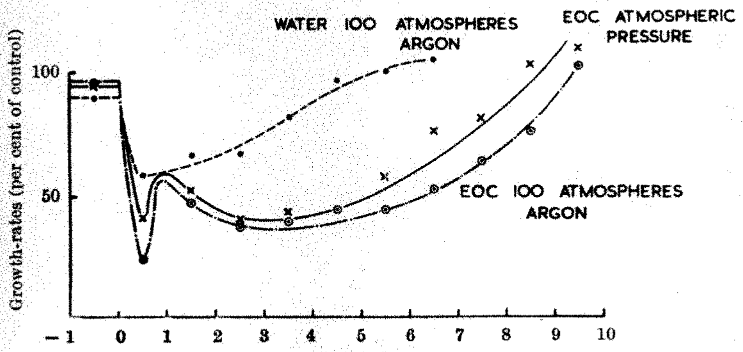

Fig. 2. Ethoxycaffeine (EOC) and 100 atm. argon (3 hr.)

the tentative conclusion is that the argon pressure had no effect on the sensitivity of the roots to 8-ethoxycaffeine. Perhaps there is such an effect, but the threshold pressure is greater than when X-rays are the injurious agent. To test this, the experiment was repeated, but 100 atm. pressure of argon was introduced. As the control roots had already reacted unfavourably to 4 hr. in 5 atm. pressure, the duration of the treatment was reduced to 3 hr. in an attempt to reduce this unwanted effect. The growth-rate curves are shown in Fig. 2. The argon treatment alone reduces the growth-rate, but there is complete recovery after 4–5 days. At this time the roots treated with 8-ethoxycaffeine still have a much-reduced growth-rate (about 50 per cent normal), and there is little difference between those treated with the added argon and those without it.

The conclusion is that argon pressures which completely annul the enhanced sensitivity to X-rays produced by oxygen have no effect on the sensitivity to 8-ethoxycaffeine, although this sensitivity also depends on the presence of oxygen. This conclusion cannot be drawn with the certainty we would like, because the control roots were adversely affected by the argon pressure, but it seems to be the most probable interpretation of the results. Its importance is that the site of action of oxygen in the X-ray case would then be different from that involved with 8-ethoxycaffeine. Kihlman[5] has shown that sodium azide, which inhibits cytochrome oxidase and thereby respiration, suppresses the power of 8-ethoxycaffeine to cause chromosome breakage as completely as anærobic conditions. The effect is also suppressed by 2.4-dinitrophenol, which uncouples phosphorylization from oxidation. These observations suggest that the site of action of oxygen in this case is the mitochondria, that is, in the cytoplasm. On the other hand, the respiratory mechanism seems not to be involved in the X-ray breakage of chromosomes, and there is reason to believe that both the oxygen and the track of ions must be in the immediate vicinity of the chromosomes, that is, in the nucleus. Ebert, Hornsey and Howard (*loc. cit.*) have shown the importance of the lipid/water partition coefficient of the added gas and have suggested that it excludes oxygen from some lipid/water interface which "may well be within the nucleus or associated with the nuclear membrane". Kihlman[6] reported that a considerable number of purine derivatives could produce chromosome aberrations in plant chromosomes, and these could be divided into two classes. The first, of which 8-ethoxycaffeine is an example, acts in relatively high concentration and short exposure times, whereas the second acts in dilute solution applied for times of the order of the mitotic cycle. If a concentrated solution of the second class is used, less effect on the chromosomes is produced, but there is a marked inhibition of mitosis. Kihlman made a strong case for the view that compounds of the first type could pass through the nuclear membrane, whereas those of the second could not, but produced their effect only on the chromosomes of dividing cells. He then showed that the first class had a lipid/water solubility ratio greater than unity, ranging up to about 10, whereas those of the second class had a ratio less than unity, ranging down to 0·04. He concluded from this that the nucleus was surrounded by a lipid/water interface which he called the "perinuclear layer". This might well be the "lipid/water interface . . . associated with the nuclear membrane" suggested by Ebert, Hornsey and Howard.

This work has been done in the laboratory of the Research Unit in Radiobiology of the British Empire Cancer Campaign at the Mount Vernon Hospital and the Radium Institute, Northwood, while on sabbatical leave from the New Zealand Branch. I thank the director, Dr. L. H. Gray, for the facilities he has given me, and the New Zealand Branch for making the visit possible. The high-pressure chamber was loaned by the Experimental Radiopathology Research Unit of the Medical Research Council, for which I am grateful to the director, Dr. G. Popjak.

Ultra-structure of the Insect Ear

Light microscope studies[1-4] have long established that the sensory unit (chordotonal sensillum or *stiftführendes Organ*) of the insect ear consists of three cells, namely, the bipolar neuron, the axon of which runs directly to the central nervous system, the sheath cell, which surrounds the dendrite of the neuron, and the attachment cell, which appears to anchor the whole assembly to the ear-drum. The approximate topographical arrangement of these cells and their inclusions are shown in Fig. 1. Examination of fresh material with the phase-contrast microscope by one of us (E. G. G.) has demonstrated that, though the vacuole (*v*) is a fixation artefact, the scolopale and the axial fibre are distinguishable *in vivo*. It is with the fine structure of the latter that this communication is principally concerned. All material has been taken from the auditory ganglia of adult female locusts (*Locusta migratoria migratorioides*) and fixed with 1 per cent osmium tetroxide buffered at *p*H 7·4 with veronal acetate. Each ganglion contains about eighty sensory units of the type described.

We confirm that the axial fibre enters the central end of the scolopale (Fig. 1) and reaches far up its axis, though we have not yet been able to trace it to contact with or passage through the cap. At the level indicated in Fig. 2 a transverse section discloses that the fibre (Fig. 2,*b*) consists of an outer ring of nine fibrillar elements and an inner group which may be two pairs of fibrils. At the level of the central end of the scolopale, this fibrillar structure is lost and the axial fibre becomes a single solid rod with cross-striations of dense lines (period 700 A.) with two wider and less dense bands between each pair of lines (Fig. 3). As this rod approaches the nucleus of the neuron it splits repeatedly into rootlets (Fig. 4). As many as forty rootlets have been counted in transverse section and each has a similar periodic structure to the parent rod.

The axial fibre therefore conforms closely, in the structure of both its distal and proximal parts, with what has been shown to be the fundamental structure of animal (and plant) cilia, and flagella[5,6]. Sjöstrand[7] has shown that the outer segment of the rod of the mammalian retina is connected with the inner by a cylinder of nine pairs of fibres with a striated root, and it is probably relevant that rods and cones are derived from the ciliated epithelium of the neurenteric canal. Wersäll[8] has found essentially the same structure (but without the striated root) in the kinocilia of the mammalian crista. Motility has been asserted of the kinocilia in the cristæ of lower vertebrates, but it has not been confirmed for mammals and it would in any event not necessarily exclude a sensory function. It seems that, when a ciliary effector is transformed into a receptor in the course of ontogeny, the fundamental structure of the cilium sometimes persists: and its retention in these cases suggests that, whatever role is ascribed to it in ciliary activity, it can play the same part but in a reversed sense in the receptor process.

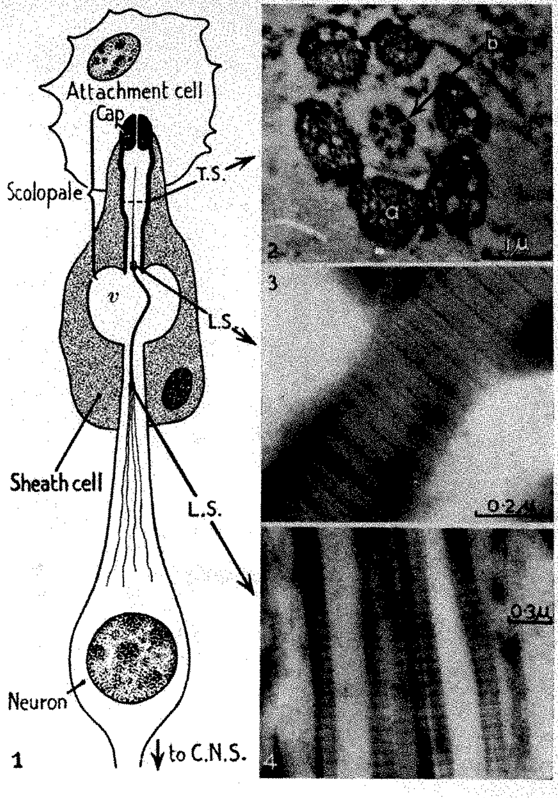

Fig. 1. (1) Diagram of light microscope preparation showing one sensory unit of the locust ear (Bouin fixed: hæmatoxylin and eosin stained). Figs. 2–4. Sections at various levels of Fig. 1 (electron microscope). Fig. 2,*a*, one of six or more pillars of finely vesiculated material forming the wall of scolopale

In insects, ciliary and flagellar effectors (except for the tails of spermatozoa in some genera) are wholly lacking in all members of the class and at every stage in the life-cycle. There is here no question of their transformation into receptors during the development of an individual. The occurrence in insects of the ciliary ultra-structure in what are unquestionably receptor cells of extremely high mechanical sensitivity is therefore of considerable interest.

We are much indebted to Prof. J. Z. Young for providing facilities and equipment for this work, to the Anti-Locust Research Centre for a constant supply of fresh material and to Dr. J. D. Robertson for much helpful advice.

Relation between Nucleolar Volume and Cell Body Content of Ribonucleic Acid in Supra-optic Neurones

During an investigation of the influence of increased functional activity on the ribonucleic acid in neurosecretory cells of the supra-optic nucleus of the rat, an observation of more general interest was made. The amount of ribonucleic acid in the cell bodies was measured microchemically[1] and the volumes of their nucleoli were determined on stained slides. Cells from control animals were investigated as well as from animals that had been subjected to administration of sodium chloride for two months. Apart from the finding that increased functional load (increased hormone production) gives rise to statistically significant increases in amounts of ribonucleic acid and nucleolar volumes, it was found that the ribonucleic acid content per cell body was directly proportional to the nucleolar volume (Fig. 1). The ribonucleic acid content per cell body nearly equals that of the cytoplasm in these cells, so it is apparent that there is a proportionality between nucleolar volume and cytoplasmatic content of ribonucleic acid. On the other hand, it can be shown that it is unlikely that proportionality between nucleolar volume and nucleolar amount of ribonucleic acid should exist as well as proportionality between nucleolar and cytoplasmatic amounts of ribonucleic acid.

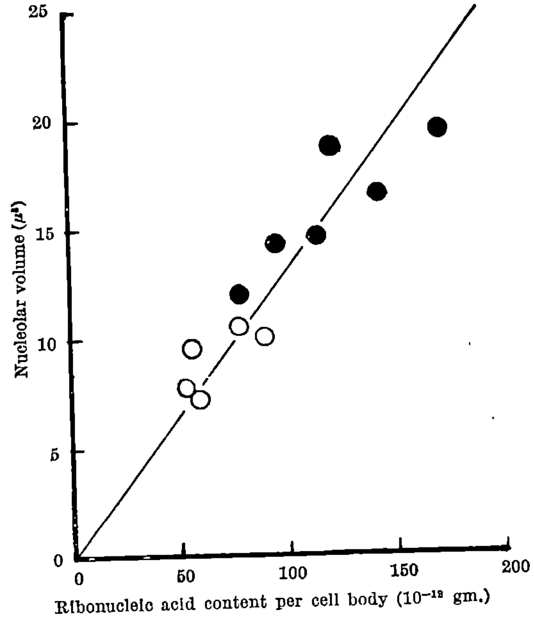

Fig. 1. Values for nucleolar volumes plotted against values for ribonucleic acid content in cell bodies of supra-optic neurones. Mean values per animal are given. Open circles designate controls, filled circles experimental animals

It is of interest to note that LaVelle[2], from a study of stained slides, came to the conclusion that there exists a proportionality between the size of the nucleoli and the amount of Nissl substance in nerve cells proper. As the basophilia of the Nissl substance is due to ribonucleic acid, these results are in good agreement, indicating that the relations may have more general application.

A full account of this investigation, which was supported by grants from the Swedish Medical Research Council and Deutsche Forschungsgemeinschaft, will be given in *Zeitschrift für Zellforschung*.

Antigenicity of Avidin

Avidin has been shown to bind the vitamin biotin, but the mechanism of binding is still unknown. Modification of the avidin molecule by acetylation, esterification or by blocking the amide, guanidyl, imidazole and phenolic groups did not result in a loss of its ability to bind biotin[1].

The mechanism and site of binding of an antigen by its homologous antibody is also largely unknown. In an effort to answer the question whether the locus (loci) of binding of biotin by avidin (on the avidin molecule) was (were) the same or one of the loci binding antiavidin to avidin, we have studied the specific precipitation of avidin by rabbit antiavidin serum in the presence and absence of biotin. Avidin concentrates were prepared according to Dhyse[2], and adult male rabbits were immunized by bi-weekly parenteral administration of these concentrates mixed with Freund's adjuvant supplied by the Difco Co. In all, two courses of immunization were employed. The avidin used for the precipitin reaction was obtained by dialysis of these concentrates, when avidin formed a precipitate. The dialysis was carried out against distilled water over a 48-hr. period with 3–4 changes of the water. The precipitin reaction was carried out according to standard methods[3] first at 37° C. for 3 hr. and then at 5° C. for 48 hr. The results are given in Table 1.

Protein was estimated according to Lowry *et al.*[4] In one series (*A*) of experiments the precipitation of avidin in the absence of biotin was studied as a control. In the *B* series, 5γ of biotin were added to the avidin and incubated at 37° C. for 1 hr. At the end of this period, antiserum was added and the incubation continued for 3 hr. at 37° C., and the precipitation continued for 48 hr. in the refrigerator. In the *C* series, precipitation of avidin was effected first and then 5γ of biotin were added. The results do not show any marked enhancement or inhibition of precipitation of avidin by its homologous antiserum, in the presence or in the absence of biotin. The binding of the antibody was not affected by the previous formation of the avidin–biotin complex

Table 1. Precipitation of Avidin by Rabbit Antiavidin

No.	Amount avidin (γ)	Total protein precipitated, using 1 ml. of serum		
		Exp. *A*	Exp. *B*	Exp. *C*
1	29·6	430	345	364
2	59·2	705	690	664
3	88·8	940	920	1,004
4	118·4	1,100	1,265	1,284
5	148·0	1,530	1,505	1,484
6	222·0	1,635	1,605	1,689
7	296·0	1,605	1,695	1,914

(Exp. *B*). It is rather hard to be definite about this for the following reasons :

(1) The best preparation of avidin binds only about 1/120 of its weight of biotin, whereas many more times its weight of antibody is bound.

(2) The binding site of biotin may be only one of the several patches where antiavidin is bound. Loss of one of these loci may not affect the precipitin reaction to a significant extent. Also, at higher concentrations of antigen, the antigen–antibody complex will become more soluble.

However, as shown by our preliminary experiments, the ability of avidin to bind biotin was not lost by previous precipitation of this protein by its antibody. Our preparations of antisera did not cross-react with ovomucoid or lysozyme, but do show a certain amount of cross-reaction with ovalbumin. Further, it is interesting to speculate whether biotin might not act as a hapten if the avidin–biotin complex were used as the antigen and if this complex were not cleaved by the intact rabbit, when administered parenterally.

Cortisone–Glucose Tolerance Test in Normal and Thyroxine-treated Rabbits

In hyperthyroidism a decreased glucose tolerance with a diabetic-like glycæmic curve has been found by some authors[1–3]. Some of them ascribe this change to the damage caused to the pancreas by the toxic effect of thyroxine on β-cells of Langerhans islets[4,5], others to the relative or absolute insulin deficiency[1]. However, Amatuzio *et al.*[6,7], in their studies on patients with hyperthyroidism, showed that both the rate of disappearance of glucose during the intravenous glucose tolerance test and the glucose tolerance are normal or increased. This observation has been confirmed by my own studies on patients and experimental animals[8]. Recently, Conn and Fajans[9,10] have suggested the use of the cortisone–glucose tolerance test for investigating the latent insufficiency of insulin secretion in the non-diabetic relatives of known diabetics. Since the rapid intravenous glucose tolerance test in animals with hyperthyroidism was within the normal range[8], the cortisone–glucose tolerance test was employed for ascertaining the latent damage to the pancreas.

Table 1. Values of the Assimilation Coefficient of Glucose in the Intravenous and Cortisone–Glucose Tolerance Test in Normal and Thyroxine-treated Rabbits

State	No.	Test	Assimilation coefficient	*P*
Normal	7	GTT*	1·16 ± 0·18	—
Thyroxine-treated	7	GTT*	1·29 ± 0·25	>0·1
Normal	7	C–GTT†	1·10 ± 0·16	>0·1
Thyroxine-treated	7	C–GTT†	2·01 ± 0·52	<0·01

* Intravenous glucose tolerance test. † Cortisone–glucose tolerance test.

In a group of normal rabbits and rabbits with experimental hyperthyroidism (induced by treatment with 0·25 mgm./kgm. body-weight thyroxine per day for 10 days) a rapid intravenous glucose tolerance test was performed and the tolerance was evaluated by determining the assimilation coefficient of glucose[11–13]. In the cortisone–glucose tolerance test 5 mgm. of cortisone acetate were administered intramuscularly 4 hr. before the intravenous glucose tolerance test. The results of our observation are given in Table 1. In normal rabbits the average value of the assimilation coefficient of glucose is 1·16 ± 0·18 ; after treatment with cortisone it was found to be slightly, though not significantly, decreased to 1·10 ± 0·16. In rabbits with hyperthyroidism it was 1·29 ± 0·25. This did not decrease even after administering cortisone (which would point to a latent insulin deficiency), but actually increased by a significant amount to 2·01 ± 0·52, which shows an accelerated rate of disappearance of glucose, increased rate of utilization of glucose and improved glucose tolerance. The exact nature of this change of assimilation coefficient of glucose cannot as yet be explained fully. It may occur in one of the following ways : either the organism of thyroxine-treated rabbits is in a state of excessive excitement[14], so that slight hyperglycæmia after the administration of cortisone causes an increased secretion of insulin which accelerates the rate of disappearance of glucose, or thyroxine affects the response of carbohydrate metabolism to cortisone.

A Highly Sensitive Assay for Œstrogens

The accepted criterion of response in the intravaginal Allen–Doisy assay is cornification of the vaginal epithelium, which occurs 48–54 hr. after administration of an effective dose of œstrogen[1,2]. Cornification is the end-point of a lengthy chain of events involving cell multiplication and growth of the epithelium.

Biggers and Claringbold[3] have shown that, in the mouse, the earliest morphological response to the intravaginal administration of œstrone, is an increase in the mitotic rate of the vaginal epithelium. After a latent period of about 12 hr. the mitotic rate increases exponentially until 30–36 hr. after injection. Since it is probable that œstrogens act by stimulating cell division, without having any other effect on the cornifying cells, it was thought that a quantitative investigation of the mitotic rate of the vaginal epithelium 17–24 hr. after hormone administration might throw some light on the primary action of œstrogens.

Randomly bred ovariectomized albino mice have been used in this study. Two weeks before use they were primed by the subcutaneous injection of 1 μgm. œstrone in peanut oil. Individual animals were allotted to the experimental groups with tables of random numbers. Œstrogens were administered in one intravaginal injection of 0·01 ml. distilled water. 7 hr. before each animal was killed 0·1 mgm. colchicine, in 0·05 ml. distilled water, was injected subcutaneously, in order to arrest mitoses. 24 hr. after injection, the vagina was removed, fixed in Barr's fixative and embedded in wax. Transverse sections 6μ thick were stained in Heidenhain's hæmatoxylin. All observations were made with a binocular microscope (× 720). For each animal five fields were selected at random from the sections. The total number of arrested mitoses were counted in each field, the final score for each animal being the sum of five counts. A transformation $Y = \log_{10}(Z + 2)$ (where Z was the number of mitoses per field) was applied to the data, and analysis of variance was carried out.

Fig. 1 shows the response to various doses of œstrone. It can be seen that a maximum response is elicited by 8×10^{-5} μgm. œstrone, response being approximately linearly related to log dose in the range $0\cdot5 \times 10^{-5} - 8 \times 10^{-5}$ μgm. œstrone. The low dose required to elicit a maximum response at 24 hr. confirms the suggestion of Biggers and Claringbold[4] that the greater part of a singly cornifying dose is ineffective, being lost from the vagina.

A number of assays have been carried out; the results are summarized in Table 1. Although day-to-day variations in mean response are significant, day-to-day variations in slope and variance are not. In experiments III and IV no significant difference was found between the slopes of œstrone and œstradiol-3 : 17β.

The relative potency of œstradiol-3 : 17β, in terms of œstrone, was found to be 1·68 (0·93–3·03); the 5 per cent fiducial limits follow the estimate. Biggers[5], using 500 animals, with cornification as the criterion of response, found œstradiol-3 : 17β to be significantly more active than œstrone (relative potency 1·75 (1·15–2·66)), an estimate not in discord with the above ($\chi^2_{[1]} = 0\cdot0042$, $P > 0\cdot95$).

Table 1

Experiment	Substances tested	No. of animals	Slope	Standard error of slope	Relative potency
I	Œstrone	8	105·0	23·26	—
II	Œstrone	24	121·4	25·96	—
III	Œstrone and œstradiol-3 : 17β	48	123·0	18·41	1·74 (0·97–3·49)*
IV	Œstrone and œstradiol-3 : 17β	32	83·3	16·55	1·50 (0·50–5·00)*

* The 5 per cent fiducial limits follow the estimate. Mean relative potency = 1·68 (0·93–3·03).

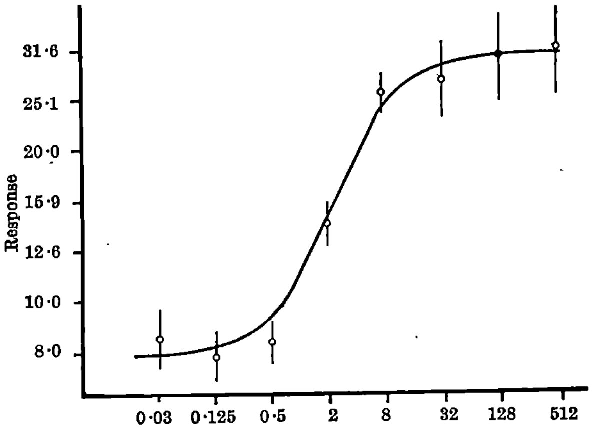

Fig. 1. The relationship of response (mean number of arrested mitoses per field) to log dose of œstrone (10^{-5} μgm.), 24 hr. after administration of the hormone. The vertical lines through the observations indicate plus and minus one standard error of the mean. The errors vary since more animals were used on the linear segment of the curve than elsewhere

The method of assay described in this communication, therefore, appears to be ten times as sensitive and four times as precise as the standard intravaginal assay under optimum conditions[4]. Preliminary work with entire immature mice suggests that the slope is doubled. Further work is being carried out with the object of increasing both slope and sensitivity of the assay method.

We are grateful to Prof. C. W. Emmens for much helpful advice and criticism. This work was supported by a grant from the New South Wales State Cancer Council.

Serological Determination of Developing Muscle Protein in Chick Embryo

Myosin in the heart muscle of a chick embryo of about 16 hr. after incubation was determined first by Ebert[1]. Further experimental work on myosin during embryonic development was published by Rudnick[2] and Grunwaldt[3] from histochemical points of view. Csapo and Herrmann[4] found a protein with solubility and viscosimetric characteristics similar to myosin in chick muscle on the ninth day of development, suggesting the possibility of its existence at earlier stages. Herrmann[5], however, reported later that muscle protein was not detectable until about the fourteenth day.

We obtained pure actin and actomyosin from the pectoral muscles of White Leghorns by Straub's method[6,7]. This protein, at a concentration of about 15 mgm. per ml., was injected intravenously into rabbits at 3-day intervals, until it reached a total of 60 mgm. The rabbits were bled by heart puncture on the fifth day after the last injection, and the serum obtained was used for the precipitin reaction with saline extracts from chick embryos[8]. We checked failure due to antigen-excess by using a constant volume of serum and progressively decreasing amounts of antigen.

Table 1. Results of Precipitin Reaction with Actin Anti-serum and Saline Extracts of Chick Embryos

Hours after incubation	No. of embryo	Antigen concentration 4 ×	8 ×	16 ×	32 ×	64 ×	128 ×	Note
24	8	− −	− −	− −				4 embryos mixed
48	8	− −	− −	− −	− −			
72	4	+ +	− ±	− −	− −	− −	− −	2 embryos mixed
96	2	+ ++	++ +++	+++ +++	++ ++	++ +	+ +	*
144	2	+ +	+ +	+ +	+ ++	++ ++	+++ +++	*
216	2	+ +	+ +	+ +	+ +	++ ++	++ +++	*
Control (non-fertilized)	8	− −	− −	− −				4 brastodics mixed

* The heart tissue was sufficiently excised.

Actin from the heart tissue and that from the striated muscle showed no difference in the reaction of anti-serum.

Table 2. Results of Precipitin Reaction with Actomyosin Anti-serum and Saline Extracts of Chick Embryos

Hours after incubation	No. of embryo	Antigen concentration 4 ×	8 ×	16 ×	32 ×	64 ×	128 ×	Note
48	12	− −	− −	− −				6 embryos mixed
72	72	− −	− −	− −	− −			* 32 embryos mixed * 40 embryos mixed
96	56	+ +	− +	− −	− −	− −		* 24 embryos mixed * 32 embryos mixed
120	6	+ +	± +	− −	− −	− −	− −	* 3 embryos mixed
168	3	+ ++ ++	++ ++ +	+ + +	− − −	− − −	− − −	* * *
240	3	+ ++ ++	++ ++ +++	+++ ++ +++	++ + ++	+ + ++	+ + +	* * *
Control (non-fertilized)	12	− −	− −	− −				6 brastodics mixed

* The heart tissue was sufficiently excised.

It was found that actin became detectable first in the chick embyro 72 hr. old (Table 1)[9]. In contrast, in the striated muscle, actomyosin was detected about 96 hr. after incubation (Table 2).

It may therefore be concluded that the stages of appearance of heart myosin, actin and actomyosin in the striated muscle occur, respectively, at about 16, 72 and 96 hr. after incubation in chick embryos. It seems that, in the heart, myosin appears before the formation of actin, while the order may be reversed in striated muscle.

A Special Reaction of the Complement Fixation Test applied to the Study of Tumours

In the course of immunological research on cancer it was observed that the foot and mouth disease virus can act as antigen in a special reaction of the complement fixation test.

For the reaction the blood serum must be fresh, correctly diluted, and not inactivated, and the reactive antigen is the foot and mouth disease virus type *O*, variation 2, obtained from a buffered extract of artificially infected bovine tongue epithelium which has been biologically titred and sterilized by filtration and is not inactivated. The other reaction elements are more or less the same as those of the normal complement fixation test: guinea pig complement and a hæmolytic system with sheep red cells and rabbit hæmolytic serum. The incubation at 37° C. is as usual.

A high proportion of normal subjects, and those suffering from various non-cancerous diseases, gave a positive serological reaction, while subjects suffering from malignant tumours, especially of epithelial origin, nearly all gave a negative serological reaction (Table 1).

Table 1

	Total No.	Positive reaction		Doubtful reaction		Negative reaction	
		No.	Per cent	No.	Per cent	No.	Per cent
Apparently normal subjects	931	911	97·85	9	0·96	11	1·18
Subjects suffering from various non-tumour diseases	367	303	82·56	20	5·44	44	11·98
Subjects suffering from malignant tumours of epithelial nature	101	6	5·94	3	2·97	92	91·08
Total*	1,309						

* The other 105 cases out of the 1,504 tested were 33 pregnant women, 35 cases not accountable at present, and 37 cases of malignant or non-malignant, non-epithelial neoplasia, and of emolymphoblastosis, which we do not discuss because of the limited number of cases.

The tongue epithelial extracts of healthy cattle or of those infected with *A* or *C* virus of foot and mouth disease and their variants did not show any antigen property in this reaction. Similarly, other antigen-viruses, such as those of fowl pox, Newcastle disease, hog cholera, herpes simplex, parotitis, yellow fever, influenza (*A*, *B*, *C* types) had no activity.

1,504 subjects of both sexes were tested, giving a total of 1,709 reactions. A number of cases were tested several times at intervals. Table 1 shows that in 97·85 per cent of apparently normal subjects the serological reaction was positive. The positivity of the reaction was not affected by age or pregnancy. For 82·56 per cent of patients suffering from various non-neoplastic diseases, both acute and chronic, the reaction was positive. The diseases included those affecting, for example, the heart, blood vessels, the respiratory system, the digestive system, the liver, the urinary system, bones and articulations, the nervous system, as well as the endocrinal diseases, infectious diseases, traumatic cases, etc., and especially syphilis and tuberculosis. This percentage may be higher, since there is the possibility of undiagnosed cancer. On the other hand, for 91·08 per cent of subjects suffering from malignant tumour of epithelial nature the serological reaction was negative.

Similar results were obtained in preliminary experimental researches on animals. Healthy rats (Spague-dowle blood stock, male) gave positive serological reactions, while rats of the same stock, carriers of Walker tumours for twenty days, gave a negative serological reaction.

From researches recently started on the components of the complement, the C_3—C_4 components seem to have an important function in the mechanism of the reaction.

The diagnostic interest of this special reaction of the complement fixation test is evident. From the biological point of view a special reactive fraction is obviously deficient or inactive in the subjects suffering from malignant tumours of epithelial nature.

Effect of Aldosterone Monoacetate and Deoxycorticosterone Acetate on Alkaline Phosphatase Activity in the Liver of Rats

Recent histochemical studies have demonstrated that aldosterone increases phosphatase activity in the kidney of rats[1]. The present communication records the influence of aldosterone monoacetate and deoxycorticosterone acetate on alkaline phosphatase activity of the liver of rats.

Young male albino rats, weighing 49·4 ± 8·9 gm., were injected subcutaneously with *d,l*-aldosterone-21-monoacetate in a daily dosage of 10 μgm. per animal for a period of 16 days. Deoxycorticosterone acetate was administered similarly (10 μgm. daily/16 days) to another group of rats. The animals were killed 24 hr. after the final injections. The liver was homogenized with water (100 ml./gm. fresh tissue), centrifuged for 5 min. at 2,000 r.p.m., and the clear supernatant was finally processed for estimation of enzyme activity according to the method laid down by Hawk *et al.*[2]. Gomori's technique[3] was used for histochemical localization of alkaline phosphatase activity. The results are presented in Table 1.

Table 1. Alkaline Phosphatase Activity in the Liver of Rats Treated with Aldosterone Monoacetate

Treatment	Alkaline phosphatase activity in the liver (mgm. phosphorus/gm./1 hr.) with S.E.*
Controls (solvent only)	2·05 ± 0·16 (7)
Aldosterone monoacetate (10 μgm. daily/16 days)	1·76 ± 0·34 (6)
Deoxycorticosterone acetate (10 μgm. daily/16 days)	1·10 ± 0·08 (7)

* Figures in parentheses indicate the number of animals.

Treatment with aldosterone monoacetate causes some inhibition of alkaline phosphatase activity in the liver albeit not in a statistically significant manner (Table 1). Deoxycorticosterone acetate evokes a similar but highly significant reduction in enzyme activity ($P < 0·001$). The difference between the two hormone-treated groups in this respect is, however, statistically insignificant. On a percentage basis, deoxycorticosterone acetate causes as much as 46 per cent inhibition, whereas aldosterone monoacetate evokes only a 14 per cent loss of enzyme activity. This suggests that deoxycorticosterone acetate is about three times as active as aldosterone monoacetate in inhibiting alkaline phosphatase activity in the liver. Histochemical preparations of liver do not show any change in the activity of this enzyme after treatment with aldosterone monoacetate, but in the deoxycorticosterone acetate group the endothelium of the vascular sinusoids reacts in a faint manner.

The present results indicate that the qualitative effect of the two hormones on alkaline phosphatase activity in the liver is more or less similar, but they differ with respect to degree. A somewhat similar view has been expressed by Loustalot and Meier[1].

Grateful acknowledgment is made to Dr. Gross of Ciba Ltd., Basle, Switzerland, for the contribution of aldosterone monoacetate.

Conversion of 3-Hydroxyanthranilic Acid to Quinolinic Acid in Presence of Rat Liver treated with 2-Acetylaminofluorene

THE reactions reported here are considered to be the final steps in the chain of reactions whereby tryptophan is converted into vitamin[1]; it shows the inhibitory action of the carcinogenic substance 2-acetylaminofluorene on the reaction 3-hydroxyanthranilic acid→quinolinic acid.

The effect of a high-protein diet on the development of tumours, when 2-acetylaminofluorene is used as the carcinogenic compound, has not as yet been clarified. Morris *et al.*[2] reported that rats maintained on a diet containing 18–24 per cent casein, after administration of 2-acetylaminofluorene, showed a high number of tumours when compared with rats maintained on a 12 per cent casein diet.

Engel *et al.*[3] noticed that the number of weaned rats in which mammary tumours caused by 2-acetylaminofluorene were observed, decreased when casein was increased in the diet. Harris[4] states that the development of liver tumours due to 2-acetylaminofluorene does not depend on the protein-level of the diet.

Dunning *et al.*[5] investigated the connexion between diet and incidence of cancer due to 2-acetylaminofluorene. They found that bladder cancer arose in all rats (Fisher stock 344) which were fed on a diet containing large amounts of tryptophan (1·4–4·3 per cent). Rats fed on a diet containing smaller amounts of tryptophan showed no development of bladder cancer.

The high level of tryptophan in the diet necessary for the development of tumours recalls that the two *o*-aminophenols, that is, 3-hydroxyanthranilic acid and 3-hydroxykynurenine, formed in the degradative metabolism of tryptophan possess carcinogenic activities. Yet if 2-acetylaminofluorene induced a biochemical lesion at a stage when one of the transformation reactions of these two compounds takes place, it would be possible to formulate a hypothesis on the mechanism of the carcinogenic activity of 2-acetylaminofluorene on the bladder, based on the accumulation of one or both of these *o*-aminophenolic derivatives.

Our experiments were conducted on liver of rats maintained on a diet containing 2-acetylaminofluorene of Hoffmann–La Roche (0·1–0·2 per cent in the diet) for periods varying from 2 to 6 days.

Liver taken from rats of the same stock, of similar weight and age, fed on the same diet but without 2-acetylaminofluorene, was tested for its capacity to convert, under the same experimental conditions, 3-hydroxyanthranilic acid (3 mgm.) into quinolinic acid (incubation time always 1 hr.).

The method used for determining quinolinic acid was a slight modification of that of Rabinovitz, Fineberg and Greenberg[6,7].

The results of these experiments clearly demonstrate that, after administration of 2-acetylaminofluorene, the enzymic reaction, that is, the conversion of 3-hydroxyanthranilic acid to *o*-quinoneiminic compound, in liver tissue is highly inhibited; this inhibition results in an average value of about 50 per cent. In one of the experiments 504 µgm. of quinolinic acid was formed in the presence of normal rat liver; 210 µgm. quinolinic acid was formed in the presence of liver of a rat treated with 2-acetylaminofluorene.

The following possible mechanism would explain the carcinogenic activity of 2-acetylaminofluorene: 2-acetylaminofluorene inhibits the conversion of 3-hydroxyanthranilic acid to the *o*-quinoneiminic compound and causes an accumulation of 3-hydroxyanthranilic acid and 3-hydroxykynurenine. These physiological metabolites could in certain conditions lead to tumour formation.

It is important to notice that the reaction of 3-hydroxyanthranilic acid is already inhibited 24 hr. after administration of 2-acetylaminofluorene, while according to Wilson *et al.*[8] tumours arise only after 3–4 months. Therefore the biochemical lesion caused by the carcinogenic compound would appear very early.

Demonstration of Antibody in Passive Transplantation Immunity to Crocker Tumour in Mice, using the Schultz–Dale Technique

MITCHISON[1] reported a simple and effective procedure for passively transferring transplantation immunity to a mouse lympho-sarcoma by injecting minced, regional lymph nodes intraperitoneally and draining the grafted areas of actively immunized mice. This phenomenon was later confirmed by Billingham *et al.*[2] using skin homografts. They preferred to call it 'adoptively acquired immunity'. Using the same technique[1], a similar transfer of passive immunity to homologous or heterologous tumour transplantation was conferred upon rats[3,4]. The criteria of immunization adopted in these experiments was the ability of the animal to cause regression of a viable implant of the tumour, or to hasten the breakdown of the skin homografts.

Recently, Makari[5] introduced the Schultz–Dale technique for the detection of specific soluble antigen in the sera of carcinoma patients using uterine horns of female guinea pigs. Fink *et al.*[6] extended it to detect antibody production against tumours in mice.

Using the Schultz–Dale technique, we have made attempts to demonstrate the presence of antibody in the host during this passive transplantation tumour immunity. The criterion of immunization taken here is the ability of the host's uterus, sensitized in this way, to produce a contraction when exposed to the homologous tumour antigen *in vitro* in the Dale bath.

Pure line strains of Strong-*A* and *C*57 black mice were used and Crocker tumour was grafted into the subcutaneous tissues of both flanks. 6 draining axillary lymph nodes, 2 spleens, 1 kidney, ⅓ of a liver and 3 c.c. of serum were obtained from mice with 10–12-day-old growing Crocker tumours. These

Table 1

Treatment	Uterus from Strong-*A* mouse, grafted intraperitoneally five days before, with draining lymph nodes from Strong-*A* mice, bearing Crocker tumour (12 days old)	Normal Strong-*A* mouse uterus, similarly treated with normal mouse lymph nodes
1. *Rd*/3 rat tumour soluble protein	0	0
2. Normal mouse organ (liver, spleen, kidney) soluble protein	++	0
3. Desensitization with normal mouse organ soluble protein		
4. Crocker mouse tumour soluble protein	++++	±
5. Crocker mouse tumour soluble protein (heated)	±	0
6. Desensitization with Crocker mouse tumour soluble protein		
7. Crocker mouse tumour soluble protein	±	0
8. Acetylcholine (10 μgm./ml.)	++++	++++

were minced and injected intraperitoneally into normal female mice of the same strain. Controls were treated similarly with tissues from normal mice. Animals were killed at intervals, the uteri were removed immediately and tested in the Dale bath for sensitization, by exposing them to different test antigens and recording the reaction on a kymograph. Soluble protein, lipoprotein[7] prepared from fresh or lyophilized Crocker mouse tumour, *Rd*/3 rat tumour and normal mouse organs were used as test antigens. After contraction with one antigen, a uterus was washed completely and the same antigen was added repeatedly to test for desensitization. The reactivity of the tissue was tested with acetylcholine at the end of each experiment.

It was found that draining lymph nodes and spleens from tumour-bearing mice are very effective; the uterus so sensitized gives a positive reaction when exposed to Crocker tumour soluble protein, lyophilized Crocker tumour extract and Crocker tumour lipoprotein. After heating, the antigens do not have this effect. Other organ-grafts are not effective. No such contraction is seen in the uterus when exposed to normal mouse organ soluble protein, lyophilized normal mouse organ extract and soluble protein from *Rd*/3 rat tumour as test antigens. Heating of the lymph nodes prior to grafting also abolishes this effect. The reaction appears on the second day after grafting and disappears completely after 3 weeks. This reaction has no strain specificity; lymph nodes from Strong-*A* mice bearing Crocker tumours, grafted into *C*57 black mice and *vice versa*, also give a positive reaction.

A typical result is given in Table 1.

It was shown previously that the host animal (rat and mouse) reacts to a progressively growing transplanted tumour by developing a characteristic plasma-cellular reaction in the draining lymph node and spleen[3,8], which can be correlated with the increase of deoxyribonucleic acid and thus with protein synthesis in these organs[9]. It was suggested that the plasma-cellular response is the morphological manifestation of a systemic immune reaction, due to the antigenic stimulation from the graft, and that plasma cells are involved in the production of antibodies against the tumour[8]. Evidence has been presented by Billingham *et al.*[2] that this heightened resistance in 'adoptive immunity' is not due to passive transference of any preformed antibody from the primary hosts, but of immunologically activated tissue, which continues to function in these secondary hosts after transfer.

Although these experiments do not throw any light on this question, they demonstrate that the presence of antibody in the host is the basic mechanism involved in this passive tumour transplantation immunity. This investigation, which will be published later in detail, also confirms observations[1,3,8] that the regional lymph nodes and spleen are important seats of the host's reaction against tumour homografts, that they form antibodies and that plasma cells play an important part in their production.

This work was carried out in the Department of Experimental Pathology and Cancer Research, School of Medicine, Leeds, and I wish to thank Prof. H. N. Green for valuable advice and helpful discussion.

Anti-allergic Effect of Cortisone

Investigations on the release of histamine and slow-reacting substance from the perfused anaphylactic lung of the guinea pig reveal that cortisone is not inhibitory to the release of either substance. On the other hand, in as low a concentration as 1 in 140,000 the response of the guinea pig gut to histamine and slow-reacting substance is greatly reduced if the cortisone is left in contact with the gut for 1–3 min. Contact for 10 sec. is without significant effect so that assay of the output of histamine and slow-reacting substance is satisfactory on the isolated gut of the guinea pig. This effect, owing to the delay, may be due to intracellular action of cortisone on the effector organ.

This peripheral depressant action, which is not reported as being significant in man from clinical observations, has probably not been observed because of the concentration required to produce it. More soluble cortisone preparations, now available, should show whether this has clinical significance, since larger rapid intravenous dosage is now possible. Lower dosage of cortisone is known to inhibit antibody production and so produce a more gradual reduction in sensitivity.

These experiments will be described in detail elsewhere.

Quantitative Determination of Cholinesterase Activity in Individual End-plates of Normal and Denervated Gastrocnemius Muscle

It has been reported[1,2] that as late as two months after denervation of the gastrocnemius muscle the end-plates still reacted positively to a histochemical test for cholinesterase. The test was made by the thiocholine method of Koelle and Friedenwald[3]. Recent development of the diver technique for quantitative determination of cholinesterase activity in individual cells[4,5] has made it possible to record quantitatively the observed histochemical reaction of the end-plates after denervation.

The cholinesterase activity of end-plates from the diaphragm and the gastrocnemius muscle was first determined in normal animals. Albino mice were killed by strangulation. The diaphragm or the gastrocnemius was removed and placed for 10 min. in the incubation medium for histochemical visualization of end-plates. The medium used was essentially similar to that recommended by Koelle[6]; but the required volume was made up with 0·9 per cent saline instead of 25 per cent sodium sulphate. Inspection of the gross substance after incubation revealed the accumulated end-plates as whitish bands extending across the muscle. A small piece of the histochemically active area was cut out with scissors and was placed under the microscope on a hollow slide containing 0·9 per cent saline. Single end-plates were dissected free with the aid of a micromanipulator and were placed in divers for quantitative determination of cholinesterase activity[5]. A 5×10^{-3} *M* acetylthiocholine iodide solution was used as substrate and the measurements of activity were carried out at 25° C. The activity was calculated as the amount of carbon dioxide liberated from the bicarbonate buffer during 1 hr.

Table 1. Cholinesterase Activity of End-Plates isolated from Normal Diaphragm and Gastrocnemius Muscle and from Denervated Gastrocnemius Muscle

Mouse No.	End-plates isolated from	Cholinesterase activity of single end-plates (expressed in 10^{-5} μl. carbon dioxide per hr.)
	Diaphragm	
4		400
5		320, 350
6		420*
7		450*
	Gastrocnemius	
8		580, 500
10		1,000, 1,000
11		740, 750
12		740, 1,200, 710
	Gastrocnemius: days after denervation	
13	75	200
14	80	510, 430
15	85	170, 170

* In these experiments two end-plates instead of one were placed in the diver; the respective readings were 940×10^{-5} and 900×10^{-5} μl. carbon dioxide per hr.

Table 1 shows that end-plates isolated from gastrocnemius muscle had higher cholinesterase activity than end-plates from the diaphragm, and that the variations in the enzymic activity were considerable. It is further seen that 80 days after gastrocnemius denervation the end-plates still displayed appreciable cholinesterase activity. (The denervation was performed under ether anæsthesia; a section of the left sciatic nerve, about 10 mm. in length, was excised at mid-thigh level.)

More detailed study of the cholinesterase activity variations in end-plates and a correlation with the cholinesterase activities of the associated neurites will be attempted in later investigations.

Metabolism of the Perfused Cat Brain during Metrazol Convulsions and Electroshock

There are a number of reports in the literature that during metrazol convulsions the rate of cerebral oxygen consumption increases[1-3]. It is also generally accepted that normally cerebral oxidations proceed almost exclusively at the expense of glucose. In a previous report[4], however, it was demonstrated with the aid of radioactive glucose that, in the case of cat brain perfused with 'simplified blood' (bovine red blood corpuscles suspended in Ringer's solution containing albumin), only about 30 per cent of the carbon dioxide produced by the brain comes from the blood glucose, while the rest of the carbon dioxide is derived from the combustion of endogenous substrates. This communication reports experiments showing an increase in production of carbon dioxide by the perfused cat brain following convulsions induced by metrazol and following electroshock. The results indicate that the major part of the excess carbon dioxide is derived from unknown endogenous substrates.

Isolation of the cerebral circulation of the cat was carried out according to the method described by Geiger and Magnes[3]. Perfusion of the brain at a constant rate of blood flow and the experimental technique generally were as described previously[5]. After 34 min. perfusion, 0·6–1·2 ml. of a 1 per cent solution of crystalline metrazol in saline was injected into the perfusing blood just before it entered the carotid arteries. The injection took about 1 min. Convulsive activity was almost immediate and continued for variable short periods after the injection. It was always accompanied by typically convulsive electrocortical activity and a slight transient fall in cerebral vascular resistance.

Results from a typical experiment are given in Fig. 1. It may be seen that the convulsive episode was accompanied and followed by an increased rate of carbon dioxide production, and the percentage of carbon dioxide produced by the brain, which is derived from the blood glucose, dropped considerably. Recovery was complete in about 12 min.

The passage of electric current through the brain (10 volts, 60 cycles from a condensor stimulator) by means of electrodes placed on the exposed skull produced similar metabolic changes. The current was applied three times during the course of 2 min. for a total of 30 sec. Each time the current was switched on an immediate and rapid rise of cerebral vascular resistance was evidenced by an increase in perfusion pressure, which returned to its previous value very rapidly when the current was switched off. During the passage of current the animal showed severe

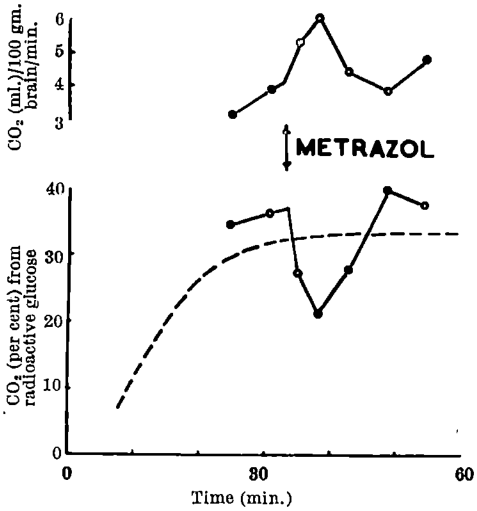

Fig. 1. Effect of metrazol on total carbon dioxide produced by cat brain perfused with simplified blood containing radioactive glucose and on percentage carbon dioxide derived from radioactive glucose. Broken line, average results of a number of control experiments (5)

tonic spasms which ceased very shortly after break of the current. In contrast to the situation prevailing after metrazol administration, electrocortical recordings following electroshock did not show evidence of convulsive activity.

Fig. 2 illustrates the rise in the rate of carbon dioxide production and the abrupt fall in the radioactivity of the carbon dioxide produced by the brain in consequence of the application of electric current. This was followed by a recovery period of about 10 min. and a subsequent 'overshoot' of short duration.

From these results it would appear that the augmented metabolic activity of the brain occurring as a result of metrazol convulsions or of electric shock, is accompanied, and possibly supported, by the oxidation of endogenous substrates within the brain. The exact nature of these substrates is not known, however, the work of Hyden on nerve cells subjected to stimulation[6], of Mullins on peripheral frog nerve[7] and of Abood and Geiger with glucose-free perfusion of cat brain[8], all seem to point to the likelihood that breakdown and oxidation of proteins or lipids may occur in association with increased neural activity.

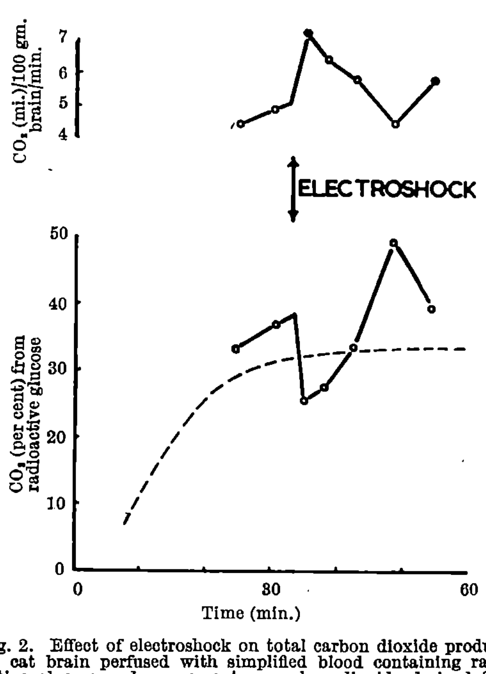

Fig. 2. Effect of electroshock on total carbon dioxide produced by cat brain perfused with simplified blood containing radioactive glucose and on percentage carbon dioxide derived from radioactive glucose. Broken line, average results of a number of control experiments (5)

We are indebted to ASSIA Chemical Laboratories, Ltd., Tel-Aviv, for a supply of metrazol.

*Iso*citritase in Germinating Marrow Seeds

Heumann[1] showed that the conversion of fat to cellular constituents must occur during the germination of seeds of *Cucurbita pepo* (pumpkin). A route for such a conversion has been demonstrated in germinating castor beans by Kornberg and Beevers[2] which requires for its operation, in addition to the enzymes of the tricarboxylic acid cycle, *iso*citritase and malate synthetase.

$$\text{Fatty acids} \xrightarrow{\beta\text{-oxidation pathway}} \text{acetyl coenzyme } A \quad \text{oxaloacetate} + \text{acetyl coenzyme } A \rightarrow \text{citrate} \rightarrow \textit{iso}\text{citrate}$$

$$\textit{iso}\text{citrate} \xrightarrow{\textit{iso}\text{citritase}} \text{succinate} + \text{glyoxylate}$$

$$\text{glyoxylate} + \text{acetyl coenzyme } A \xrightarrow{\text{malate synthetase}} \text{malate} \rightarrow \text{oxalo-acetate}$$

Net result: 2 acetyl coenzyme $A \rightarrow$ succinate

The presence of *iso*citritase in germinating marrow seeds (another variety of *Cucurbita pepo*), and the variation of its activity with the stage of germination, suggest that this pathway may operate in the seedlings of the marrow.

Glyoxylic acid (L. Light and Co., Ltd.) was assayed by the permanganate method of Long[3], and a standard curve constructed using the colorimetric 2 : 4-dinitrophenylhydrazone method of Friedemann and Haugen[4]. A variation of the latter method, taking into account the ratio of absorption at 420 mμ and 520 mμ was used for determining total keto-acid and glyoxylic acid in mixtures of glyoxylic acid and α-ketoglutaric acid.

Seeds were germinated in darkness in vermiculite at 30° C. for periods of 1–6 days. Extracts were then prepared as follows. The testa and, when appreciable in size, the radicle and most of the hypocotyl of each seed were removed, and the remainder, virtually only cotyledons, ground at 0° C. with phosphate buffer, 0·1 M, pH 7·5 and fine

6	3·9	2·0	25·6	21·0	59·0	56·0	70·7	67·0	1·0	0·7

sand. Debris was removed by centrifugation for 15 min. at 1,500 × *g* ('International' refrigerated centrifuge), and smaller particles by high-speed centrifugation at 52,000 × *g* for one hour ('Spinco' ultracentrifuge).

Incubation was carried out under nitrogen at 25° C., each tube containing 145 µmol. 0·1 *M* potassium phosphate buffer, *p*H 7·6, 10 µmol. magnesium chloride, 10 µmol. glutathione, and 15 µmol. substrate in 1·8 ml. solution. Reaction was initiated by addition of 0·2 ml. extract, and stopped by 0·5 ml. 30 per cent trichloracetic acid, which precipitated proteins. These were centrifuged down, and the supernatant analysed for total keto-acids, and for glyoxylic acid, by the modified Friedemann and Haugen technique[4]. Chromatography of the keto-acid 2 : 4-dinitrophenylhydrazones from incubation, with known markers, using Whatman No. 3 paper and butanol/3 per cent ammonium solvent[5] showed no perceptible trace of any keto-acid other than glyoxylic and α-ketoglutaric acids.

Glyoxylic acid was further characterized by reduction of the 2 : 4-dinitrophenylhydrazone, eluted from the butanol/ammonia chromatogram, to amino-acid, using Adams's catalyst and hydrogen[6], and chromatography of the product in phenol/borate buffer[7], *p*H 9·3, with known samples of several amino-acids as markers. The chromatogram was developed by spraying with 0·1 per cent ninhydrin, 10 per cent glacial acetic acid, 4 per cent collidine in ethanol, which gave a purple spot for glycine marker. The presence of a corresponding spot for the unknown product of 2 : 4-dinitrophenylhydrazone reduction proved conclusively that there was, in fact, glyoxylic acid in the resultant solution from the incubation.

The result of the incubation was calculated as µmol. glyoxylate present in the incubated mixture per gm. ungerminated seed-weight, and tabulated (Table 1).

The extract from six-day-old seedlings was also incubated in a series of different dilutions, and the activity plotted as µmol. glyoxylate formed per hour against volume of six-day extract used. The results suggested that a linear relationship exists between these functions in the range studied, and that activity (Table 1) is proportional to concentration at all ages.

Superficial observation of the seeds during germination revealed little or no obvious change at one day, the development of radicle up to about 3 cm. long at two days, and after that the emergence and rapid elongation of the hypocotyl. On the whole the results show good correlation of *iso*citritase activity with the age and development of the seedling. The results also correspond to those of Heumann[1] for rate of increase of non-fatty dry weight of seeds of *Cucurbita pepo*, the two remaining almost proportional as the seedling develops.

The above results support the view that *iso*citritase is an enzyme of importance in the conversion of fat to carbohydrate in germinating marrow seedlings.

Thanks are due to the many who have offered advice during this investigation, especially to Dr. F. A. Isherwood for his assistance in the characterization of glyoxylic acid, Dr. G. D. Greville for a gift of sodium *cis*aconitate and for his interest, and Prof. F. G. Young for permission to carry out the research in this Department.

Coenzyme *A* and Aldolase in Rubber-bearing Plants

THERE is evidence that the biosynthesis of rubber from carbon dioxide and water in *Parthenium argentatum*[1] may proceed through acetate and β-methylcrotonate, and that acetate can also act as a precursor of rubber in *Hevea brasiliensis*[2]. Coenzyme *A* probably plays a vital part in the process. Information on the enzyme systems operating and on the co-factors actually present in rubber-bearing plants is very scanty. Coenzyme *A* has been reported[3] to be present in the seeds of *Cryptostegia* spp., of *Hevea*, and in various organs of *Taraxacum kok-saghyz*. The complete enzyme system required to incorporate acetate into rubber hydrocarbon is present in *Hevea* latex[2]; but its make-up is not yet known. This communication reports observations on coenzyme *A* in *Hevea* and *Taraxacum*, and also on aldolase, which was originally selected for study as an enzyme capable of forming carbon–carbon linkages.

Cook and Sekhar[4] have separated *Hevea* latex by ultra-centrifugation into one minor and three major fractions. Of these, 'bottom fraction' represents the sedimentable non-rubber particles of the latex, and '*C*-serum' the non-sedimentable aqueous phase. A rubber-free fluid known as '*F*-serum'[5] is obtained from latex by the more drastic procedure of coagulation by prolonged freezing. It is believed[6] to contain some of the components of both bottom fraction and *C*-serum.

Freeze-dried latex fractions have been supplied to the Birmingham laboratories by the Rubber Research Institute of Malaya, where these fractions, along with fresh *C*-serum, were also later examined for aldolase activity. In Birmingham, small quantities of fresh latex were obtained from 4-year-old *Hevea* trees grown in glasshouses; *Taraxacum kok-saghyz* plants were harvested on the point of flowering.

Coenzyme *A* was determined by the method of Hübscher, G., and Wakil, S. J. (unpublished work). The fatty acid-activating enzyme prepared from ox liver[7] was used to catalyse the reaction between sorbic acid and coenzyme *A* to give sorbyl–coenzyme *A*, the formation of which can be measured spectrophotometrically at 295 mμ. Under the test conditions all the coenzyme *A* present is transformed into sorbyl–coenzyme *A*.

The coenzyme *A* content of some *Hevea* and *Taraxacum* materials is shown in Table 1.

Table 1

Material	Coenzyme *A* content in μmol. per 100 mgm. (dry weight)
Freeze-dried *F*-serum (*Hevea*)	
2·5 yr. after preparation	0·02
7 months after preparation	0·10
2 months after preparation	0·16
Fresh latex (dialysed)	0·66
Taraxacum kok-saghyz roots	0·27

A modification of the method of Herbert *et al.*[8] was used for detecting and estimating the level of aldolase activity. The solution (2 ml.) to be tested was incubated for 20 min. at 30° with sodium fructose-1 : 6-diphosphate solution (1 ml. 0·031 *M*) and a sodium borate buffer (2 ml.) containing hydrazine as ketone fixative. The borate–hydrazine solution had *p*H 8·5 and was 0·3 *M* with respect to BO_3^- and 0·14 *M* with respect to hydrazine. After incubation alkali-labile phosphate was estimated on aliquots of the deproteinized mixture. Unit aldolase activity was defined as the formation of 0·10 mgm. of alkali-labile phosphorus. Table 2 shows the activities observed.

Table 2

Material	Activity (units/mgm.)
Hevea	
Ammonium sulphate precipitate from aqueous extract of freeze-dried bottom fraction	0·03
Freeze-dried *F*-serum (old sample)	0·03
Freeze-dried *C*-serum (5 samples)	0·09*
Freeze-dried *F*-serum (4 samples)	0·06*
Freeze-dried bottom fraction (4 samples)	below 0·02*
Acetone precipitate from *C*-serum	0·80
Seed cotyledons	very low
Fresh latex (in Birmingham)	0·16
Taraxacum roots–ammonium sulphate ppt. of aqueous extract	0·01

* Mean values.

Aldolase of *Hevea* latex was first detected in material precipitated by ammonium sulphate (between 35 and 65 per cent of saturation) from an aqueous extract of freeze-dried bottom fraction. Examination of other latex fractions (see Table 2) suggested that the enzyme was located mainly in the aqueous non-sedimentable phase (*C*-serum) rather than in the sedimentable particles. It will be noted that *F*-serum is less active than *C*-serum, as expected from the mode of preparation.

The activity present in *C*-serum was largely precipitated by ammonium sulphate between 35 and 65 per cent of saturation. A better fractionation of *C*-serum was, however, achieved by treating it with increasing amounts of acetone at 0°. The material precipitated between 30 and 50 per cent (v/v) of acetone was dissolved in water and, after removal of insoluble matter, freeze dried. The product (see Table 2) had 8–9 times the activity of unfractionated freeze-dried *C*-serum.

In the light of recent publications[1,2] on rubber biogenesis it seems unlikely that aldolase is directly involved in the synthesis of the hydrocarbon, but it is of considerable interest as a key enzyme in the carbohydrate metabolism of latex. So far as we are aware, coenzyme *A* has not been directly demonstrated in *Hevea* latex hitherto, although the results of Teas and Bandurski[2] seem to imply its presence.

We are indebted to Prof. M. Stacey for his interest and encouragement, to Messrs. B. C. Sekhar, R. C. H. Hsia and Y. H. Chong for the preparation of materials from *Hevea*, to Mr. W. G. Wren, of the Rubber Research Institute of Malaya, and to Dr. B. L. Archer, of the British Rubber Producers Research Association, for their assistance and advice, and to the Dunlop Rubber Company for a scholarship awarded to one of us (J. A. G.).

Para-Amino-Benzoic Acid and Sulphanilamide in the Nutrition of *Neurospora crassa*

THE action of sulphanilamide, an antivitamin of *p*-amino-benzoic acid, has been traced to an impairment of the synthesis of methionine and adenine, besides some other compounds[1]. In some cases *p*-amino-benzoic acid could reverse the inhibitory effects of sulphanilamide, whereas folic acid could not[2]. In our present work, we studied the reversal of the toxicity of sulphanilamide in *Neurospora crassa* 8*a* (wild) and the substitution of *p*-amino-benzoic acid in a strain without the acid (No. 1633) of the same mould.

The cultures were grown with sulphanilamide or with *p*-amino-benzoic acid, as shown in Tables 1 and 2, on the usual basal medium (Horowitz and Beadle, 1954). The *p*H of all media was adjusted to 6·8 before autoclaving. Volatile and heat-labile substances were added after sterilization by filtration through a Seitz pad. The cultures were grown at room temperature (26–28° C.) for three days and then the mats were filtered, dried and weighed.

Table 1. REVERSAL OF THE TOXICITY OF SULPHANILAMIDE TO *N. crassa* 8a
(10 ml. medium with 5 mγ biotin. 72-hr. growth)

No.	Additions	Weight of mycelium (mgm.)
1	Basal medium	47·5
2	(1) + 5 mgm. sulphanilamide	0·6
3	(2) + 10γ *p*-amino-benzoic acid	39·2
4	(2) + 2 mgm. adenine	10·3
5	(2) + 2 mgm. guanine	8·5
6	(2) + 2 mgm. uracil	6·1
7	(2) + 2 mgm. choline	11·6
8	(2) + 2 mgm. threonine	0·6
9	(2) + 2 mgm. valine	9·5
10	(2) + 2 mgm. methionine	12·8
11	(2) + 1 mgm. each of adenine, guanine and uracil	14·3
12	(2) + 1 mgm. each of valine, threonine and methionine	9·7
13	(2) + 1 mgm. each of adenine, guanine, uracil, valine, threonine and methionine	34·1
14	(2) + 80 mgm. vitamin-free casein hydrolysate	24·1
15	(14) + 2 mgm. each of adenine, guanine, and uracil	39·5

These results indicate a broad spectrum for the antivitamin action of sulphanilamide. Thus, while methionine, valine, threonine, adenine, guanine and uracil were active by themselves to a certain extent in reversing the growth inhibition of the sulpha drug, a mixture of these six compounds was almost as active as *p*-amino-benzoic acid itself. The ability of casein hydrolysate to reverse this toxicity to a greater extent than a mixture of the above three amino-acids may suggest a synergistic role for other amino-acids in reversing the action of the sulphanilamide. My unreported results show that while hypoxanthine was active to a certain extent in reversing the toxicity of sulphanilamide, neither xanthine nor uric acid was active. Also, while folic acid was a complete substitute for *p*-amino-benzoic acid in mutant 1633, it was of limited activity in reversing the effects of sulphanilamide. Glutamic acid (cf. Table 2) could replace *p*-amino-benzoic acid to a slightly greater extent than aspartic acid could. In *E. coli* the inhibition of 2-chloro-4-aminobenzoic acid could be reversed by *p*-amino-benzoic acid, methionine or pantothenic acid[3]. My present results (cf. Table 1) show that the toxic effects of the sulpha drug are counteracted almost completely by a mixture of valine, threonine, methionine, adenine, guanine and uracil. This may very likely mean that the toxicity of sulphanilamide in this case is entirely confined to the synthesis of C_1 units.

The results on the replacement of *p*-amino-benzoic acid (cf. Table 2) show that methionine was a complete substitute for the acid. This may denote that the metabolic block in this mutant is at the level of the synthesis of methionine, especially as the other amino-acids and purine and pyrimidine bases were not active. Strehler[1] found that folic acid, methionine and *p*-toluidine are capable of replacing *p*-amino-benzoic acid in *Neurospora* 8043 *M*. He found that in the presence of sulphanilamide the mutant will not grow on adenine or other purines, although all were active in combination with methionine. Again, in my experiments, aspartic and glutamic acids were active to a certain extent in replacing *p*-amino-benzoic acid. This result is difficult to interpret since these two amino-acids are not known to contribute C_1 units to any significant extent. Koft *et al.*[4] found that α-ketoglutaric acid, pyruvic acid and lactic acid replaced *p*-amino-benzoic acid in the early growth of *Lactobacillus arabinosus*. However, lactic acid was inactive in my experiments with *Neurospora crassa* 1633.

Table 2. REPLACEMENT OF *p*-AMINO-BENZOIC ACID IN THE NUTRITION OF THE MUTANT WITHOUT *p*-AMINO-BENZOIC ACID (1633)
(10 ml. medium with 5 mγ biotin. 72-hr. growth)

No.	Addition to the basal medium	Weight of mycelium (mgm.)
1	None	Negligible
2	*p*-Amino-benzoic acid (10γ)	25·6
3	Methione (2 mgm.)	27·4
4	Valine (2 mgm.)	0·8
5	Threonine (2 mgm.)	0·8
6	Adenine (2 mgm.)	1·1
7	Guanine (2 mgm.)	2·0
8	Uracil (2 mgm.)	Negligible
9	Choline (2 mgm.)	Negligible
10	Folic acid (100γ)	23·8
11	Lactic acid (10 mgm.)	2·5
12	Casein hydrolysate (vitamin free, 80 mgm.)	20·4
13	Calcium pantothenate (100γ)	Negligible
14	Aspartic acid (5 mgm.)	12·3
15	Glutamic acid (5 mgm.)	17·0

2 mgm. of each (separately) of the following compounds did not support the growth of this mutant in the absence of *p*-amino-benzoic acid: serine, cystine, tyrosine, histidine, arginine and tryptophan.

Ferulic and *p*-Coumaric Acids in Pineapple Tissue as Modifiers of Pineapple Indoleacetic Acid Oxidase

PINEAPPLE stem tissue has been shown[1] to contain a powerful indoleacetic acid oxidase system and a polyphenolic-type inhibitor. Other reports demonstrate the ability of certain phenols to stimulate or inhibit the indoleacetic acid oxidases of peas[2], lentils[3], wheat[4], a fungus[5], and lupins[6], though none of the phenols has been shown to accompany these systems.

We have now found that two cinnamic acid derivatives accompany and modify the activity of the indoleacetic acid oxidase in both pineapple stem and basal leaf tissue. Both occur naturally as esters which are extractable into ether from aqueous tissue homogenates at *p*H 2·5. With ascending paper chromatography in 8/1/1 *iso*propanol–28 per cent ammonia–water, the esters have an R_F of approximately 0·05–0·2, and in 4/1/1 butanol–acetic acid–water, an R_F of approximately 0·85, with considerable overlapping of the two esters.

The ether extractives were hydrolysed with *N*/10 sodium hydroxide at 100° C. for 2 hr., the *p*H adjusted, and the free acids extracted into ether. Chromatography now showed the disappearance of the original material and the appearance of two adjoining spots at a higher R_F (0·37–0·45) in the alkaline solvent. These two areas were identical with ferulic and *p*-coumaric acids in R_F, colour of ultra-violet fluorescence, and acidic and basic colours with diazotized sulphanilic acid and diazotized *p*-nitroaniline sprays. The ultra-violet absorption spectra of the liberated acids were superimposable on those of the known compounds following double chromatography with *iso*propanol–ammonia–water. The presence of *p*-coumaric acid was further demonstrated by absorption spectra in alcoholic sodium ethoxide, chromatography in a number of solvents, by isolation and formation of derivatives[7].

Enzyme extracts were treated with $M/200$ hydrogen peroxide to destroy the inhibitor and stimulator by peroxidative action. In the absence of a suitable phenolic compound, no enzyme activity occurred, whereas with added *p*-coumaric acid, treated extract equivalent to 2·4 mgm. wet tissue and containing 14γ protein destroyed 262γ indoleacetic acid in 10 min. Assays showed that *p*-coumaric acid or its naturally occurring ester is loosely combined as a coenzyme for and in mass action equilibrium with pineapple indoleacetic acid oxidase. Ferulic acid at low levels can stimulate partial enzyme activity when little or no *p*-coumaric acid is present; at higher levels, ferulic acid or its ester is a powerful enzyme inhibitor.

In vitro Culture of Ovaries of *Iberis amara* L.

FRUIT culture, perhaps better termed ovary culture, aims at studying the growth pattern and nutritional requirements of growing ovaries. Two pioneer attempts in this direction were those of Jansen and Bonner[1] and Nitsch[2,3], but these workers did not follow the changes taking place in the ovules. Recently, Anantaswamy Rau[4] reared the ovaries of *Phlox* in artificial cultures. Although the fruits grew appreciably in all these cases, the extent of growth never equalled that in Nature. The size of the fruits obtained was always much smaller than that of fruits produced in Nature.

We cultured ovaries of *Iberis amara* and studied the effect of several chemicals on the development of the pericarp as well as the ovule.

In Nature the ovaries become double their initial size in a week after pollination, and the fruits attain their maximum size at the end of two weeks. Further changes, such as the differentiation of pericarp and the maturation of the seeds, continue for another week.

We took flowers one day after pollination (Fig. 1, 1), when the ovules contain a zygote or a 2-celled proembryo and a varying number of endosperm nuclei. The flowers were sterilized with 'Chlorox' and planted in Nitsch's basic medium supplemented with vitamins. The development obtained in this medium compared very favourably with that in Nature. Here the ovaries matured and the ovules showed normal embryos and endosperm on dissection.

Having obtained normal growth in the above medium, our next problem was to analyse the minimal requirements for fruit growth. Ovaries were cultured in water; sugar + agar; sugar + agar + minerals (made according to Nitsch); sugar + agar + minerals + vitamins[5]; sugar + agar + minerals + vitamins + indolylacetic acid; and so on.

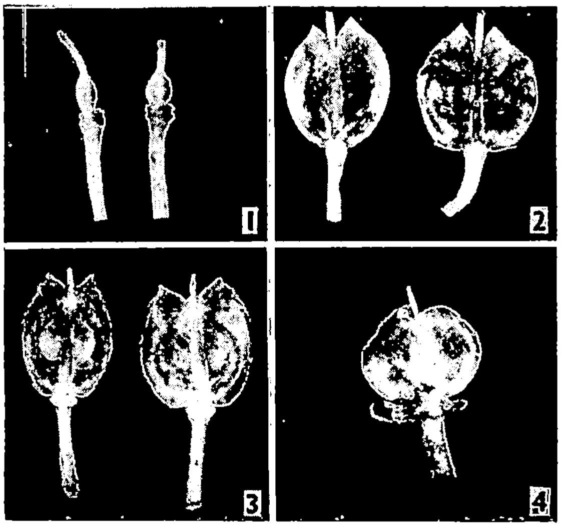

Fig. 1. (1) Ovaries at the time of planting of flowers (one day after pollination) (× *c.* 2). (2) Two-week old control fruits (× *c.* 2·2). (3) Two-week old *in vitro* fruits grown on Nitsch's basic medium supplemented with indolylacetic acid 5 mgm./l. (× *c.* 2). (4) Three-week old fruit grown on a medium containing 0·5 mgm./l. of kinetin and 2 mgm. of 2,4-dichlorophenoxyacetic acid. The ovules failed to mature into seeds in this series (× *c.* 2·7)

We maintained two sets in water: one with single flowers and the other in which whole inflorescences were taken. The initial size of the ovaries was 3·7 mm. × 2 mm. Growth was poor in both cases and ceased completely at the end of one week. As expected, the fruits on the inflorescences were larger (5·4 mm. × 3 mm.) than those formed from single flowers (4·6 mm. × 2·5 mm.). Microtome sections revealed that in the case of single flowers there was no formation of embryo or endosperm. In ovaries collected from inflorescences the embryo had grown to the globular stage and was quite healthy, but the endosperm, especially in the neighbourhood of the embryo, had started degenerating.

Ovaries cultured on 5 per cent sugar solidified with 0·6 per cent agar grew to double their initial size in 13 days, but the fruits were extremely cartilaginous and the seeds thin and papery and devoid of an endosperm or embryo.

A marked improvement over the sugar + agar medium was seen on the addition of minerals according to Nitsch's formula. The average size of the ovary (8·6 mm. × 6·2 mm.) almost approached that of the controls (9·1 mm. × 7·6 mm.) as measured after two weeks. The growth of the embryo and the endosperm was also satisfactory.

Almost exact duplication of fruit growth as it is in Nature was achieved with sugar + agar + minerals + vitamins. Ovaries sown in this medium became almost double in size after a week. The calyx and corolla persisted for well over a week. Later the calyx turned yellowish and was shed; the corolla stayed on longer. The growth of the ovary was completed in about two weeks, when it started turning yellow (this compared well with the condition in Nature) and the seeds became brownish. Fruits maintained in culture for 36 days showed no appreciable increase in length but only slight increase in breadth. As already mentioned the embryo and the endosperm were quite comparable to those in Nature.

Next it was considered worthwhile to investigate the effect of removal of the calyx and corolla. When this was done, the growth of the ovaries always received a setback. Ovaries with calyx and corolla intact always outgrew those in which these organs had been removed. This confirms that they are not meant just to protect the essential organs but actively contribute to their development.

When indolylacetic acid (5 mgm./l.) was added to Nitsch's basic medium we obtained fruits (Fig. 1, 3) which were sometimes even larger than those set in Nature (Fig. 1, 2). Dissections of 2-week old ovaries showed normal embryo and endosperm.

The addition of kinetin alone (ranging from 0·1 to 0·6 mgm./l.) as well as in combination with indolylacetic acid (5 mgm./l.) also seemed to improve the growth of the ovaries only slightly.

On the other hand, ovaries cultivated on Nitsch's basic medium supplemented with 2,4-dichlorophenoxyacetic acid (2·0 mgm./l.) and kinetin (0·5 mgm./l.) (Fig. 1,4) showed arrested growth of both endosperm and embryo. Since growth in the kinetin medium alone is normal the retarding effect may be attributed to the 2,4-dichlorophenoxyacetic acid alone or possibly to the combined effect of 2,4-dichlorophenoxyacetic acid and kinetin.

The results described above show for the first time that not only the growth of the ovary but also that of the ovules can be maintained in an artificial medium. While the results achieved so far are significant, it remains to be seen whether unfertilized ovaries can also be grown to maturity along with concurrent growth of the ovules into viable seeds containing parthenogenetic embryos.

This work was done under a scheme of research on the chemical stimulation of ovary and ovule financed by the Indian Council of Agricultural Research. We are indebted to Prof. P. Maheshwari for his guidance and to Dr. R. C. Sachar for his active co-operation.

Formation of Oxalacetate and Aspartate from Phospho-Enol-Pyruvate in Spinach Leaf Chloroplast Extract

WHILE investigating the ability of water extracts[1] of spinach leaf chloroplasts to catalyse 'dark' carboxylation reactions, we have found that the addition of phospho-enol-pyruvate and $^{14}CO_2$ to the colourless chloroplast extract causes the accumulation of labelled oxalacetate and labelled aspartate in the reaction mixture. Bandurski and Greiner[2] using spinach leaves, Tchen and Vennesland[3] using wheat germ and spinach leaves, and Utter *et al.*[4] using bird liver, have described enzyme preparations which catalyse irreversible and reversible carboxylations of phospho-enol-pyruvate to oxalacetate. The formation of oxalacetate in our experiments indicates the presence of a phospho-enol-pyruvate carboxylase in the chloroplast. Aspartate can then be formed by transamination of oxalacetate. The rate of carbon fixation was increased when, in addition to phospho-enol-pyruvate, either alanine, glutamine or aspartic acid was added to the reaction mixture.

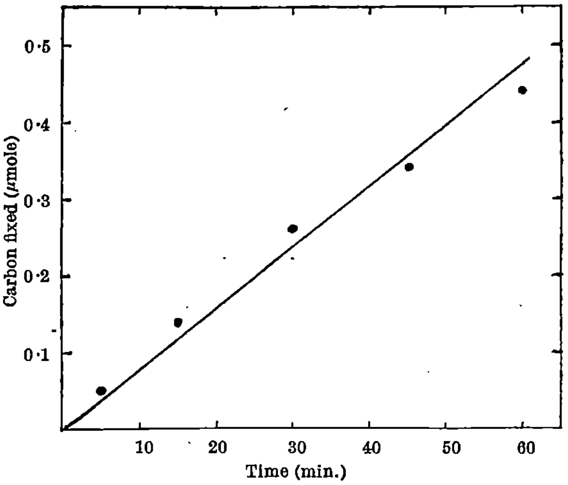

Fig. 1. Fixation of $^{14}CO_2$ into aspartate by phospho-enol-pyruvate and chloroplast extract in the dark. The composition of the reaction mixture was as follows and the components were added in the order listed: *Tris*, *p*H 7·4, 80 µmol. in 0·4 ml.; magnesium sulphate, 10 µmol. in 0·1 ml.; water, 1·1 ml.; phospho-enol-pyruvate, 6 µmol. in 0·2 ml.; chloroplast extract 1·0 ml. corresponding to 2 mgm. chlorophyll. The tube was stoppered and 3 µmol. carbon-14 labelled Na_2CO_3 (3 × 10^6 c.p.m.) in 0·2 ml. injected through the rubber stopper by syringe

Fig. 1 shows the time course of carbon fixation in an experiment with phospho-enol-pyruvate and chloroplast extract. At intervals, small samples were withdrawn from the rubber-stoppered reaction tube by syringe and added to equal volumes of 4 per cent trichloracetic acid solution. The extent of carbon fixation was estimated by counting aliquots of the acidified samples which had been plated on metal planchets and quickly dried under a heat lamp.

Samples of the reaction mixture acidified at 60 min. were chromatographed on paper in two dimensions with the solvent systems phenol/water (80/20) and butanol/acetic acid/water (52/14/35). Radio-autographs of these chromatographs showed only one radioactive spot with R_F of 0·19 in the phenol/water direction and 0·43 in the butanol/acetic acid direction. These co-ordinates suggested that the material in the radioactive spot was aspartic acid, and this was confirmed by co-chromatography with authentic aspartic acid. Like aspartic acid, the material when eluted was unchanged by heating at 100° C. in 2 *N* sulphuric acid for one hour or by treatment with alkaline phosphatase.

It should be noted that the extent of carbon fixation as determined for the experiment in Fig. 1 is underestimated to the extent that oxalacetate exists in the reaction mixtures. Oxalacetate is decomposed by the heat-drying treatment on metal planchets and loses its β-carbon as $^{14}CO_2$; it is into the β-position of oxalacetate that carbon dioxide is fixed during the enzymatic carboxylations of phospho-enol-pyruvate which have been described[2–4]. The fact that no spot corresponding to oxalacetate appears on the radioautographs is probably due to the decomposition of oxalacetate during the chromatographic procedures employed.

To determine the quantity of oxalacetate present in the reaction mixtures, samples were acidified with trichloracetic acid, a carbon dioxide–nitrogen mixture was bubbled through to remove trace amounts of $^{14}CO_2$, carrier oxalacetate was added and the samples were decarboxylated with either aluminium ions[5] or with aniline citrate[6]. The liberated $^{14}CO_2$ was collected in a solution of sodium hydroxide, converted to carbonate, and counted on planchets. Results of such experiments showed that the radioactivity originally present and due to aspartate was not affected by the decarboxylation, and that oxalacetate was formed in the reaction mixtures in concentrations about 1·3 times that of aspartate. Thus, the aspartate which was counted on heat-dried planchets represented only about four-tenths of the total carbon dioxide fixed.

When either glycerate-3-phosphate or glycerate-2-phosphate was added to the reaction mixture described earlier, oxalacetate and aspartate were formed but at a slower rate than when phospho-enol-pyruvate was used. The glycerate phosphates were probably first converted to phospho-enol-pyruvate by the action of glyceric acid mutase and enolase in the chloroplast extract. When either ribulose-1-5-diphosphate or ribose-5-phosphate plus adenosine triphosphate was added, and the reaction mixture chromatographed, labelled carbon appeared in both glycerate-phosphate and aspartate. In view of the fact that these substances are among the compounds formed when whole isolated chloroplasts fix carbon dioxide in the light[7] and since Fuller and Anderson[8] suggest the importance of aspartic acid formation as an early photosynthetic event in photosynthetic purple sulphur bacteria, we find it interesting that carboxylations in chloroplasts can lead to the rapid formation of an amino-acid.

We are indebted to Dr. Clinton Ballou for the sodium salts of phospho-enol-pyruvate and glycerate-2-phosphate.

Histogenesis of Osteoclastomata

Two of the main problems concerning the histogenesis of giant cell tumours of bones have been: (1) the nature and function of the giant cell—this has been variously classified as an endothelial cell, a foreign body giant cell, a megakaryocyte, an osteoclast or as a giant cell formed by agglomeration or fusion of stromal cells; (2) the histogenesis of the giant cell—the overwhelming consensus of opinion among the supporters and opposers of the osteoclast nature of the giant cell[1-5] suggests that the giant cells are formed from the spindle-shaped stromal cells.

In two cases of osteoclastomata recently investigated I have observed a strong acid phosphatase in the cytoplasm of the giant cells. The stromal cells gave a negative reaction. The presence of this enzyme was demonstrated both with the lead phosphate and azo-dye coupling techniques. Inhibition by 0·01 *M* sodium fluoride excluded the possibility of non-enzymatic impregnation of the giant cells[7]. Using *o*-acetyl-5-bromoindoxyl as substrate for esterases, both the stromal and the giant cells were negative for these enzymes.

These findings suggest that the giant cells are not in any way related to the stromal cells. It might be argued that the stromal cells are precursors of the giant cells with different enzyme reactions, but all the histochemical and biochemical evidence points to the fact that the enzyme systems of parent cells and their descendants are the same.

It has also been stated that the giant cells, because of their apparent age, show signs of early degeneration[2]. Histochemically, however, it would appear as if the giant cells are very active cells (probably osteoclasts) and the stromal cells inactive with regard to phosphatase and esterase activities.

Details concerning these findings and further experimental work will be published elsewhere.

Inhomogeneity of α-Casein from Goat Milk

It is now known that α-casein from cow milk, which appears electrophoretically homogeneous under many different conditions, consists of at least two compounds which have been designated α- and *k*-casein[1]. α-Casein from goat milk, which has similar properties to that from cow milk[2] and the same phosphorus content[3], showed signs of inhomogeneity during electrophoresis by the moving-boundary method[2]. Using zone electrophoresis on filter paper it has now been found that the α-component of freshly prepared goat casein does consist of at least two electrophoretically distinct fractions which, until further characterization, will be called α_1- and α_2-casein in order of decreasing electrophoretic mobility.

The experiments were made with unfractionated casein, which was obtained in the usual way by acid precipitation, and with α-casein, which was prepared from it by Warner's method[4], and had the same phosphorus and nitrogen content as α-casein prepared from cow milk.

Electrophoretic runs were made on Whatman No. 3 paper with veronal buffer, *p*H 7·6, $\mu = 0{\cdot}1$, at 3 V./cm. for 15 hr. After staining with naphthalene black 12*B* 200 the electropherograms were scanned. The scanning patterns obtained

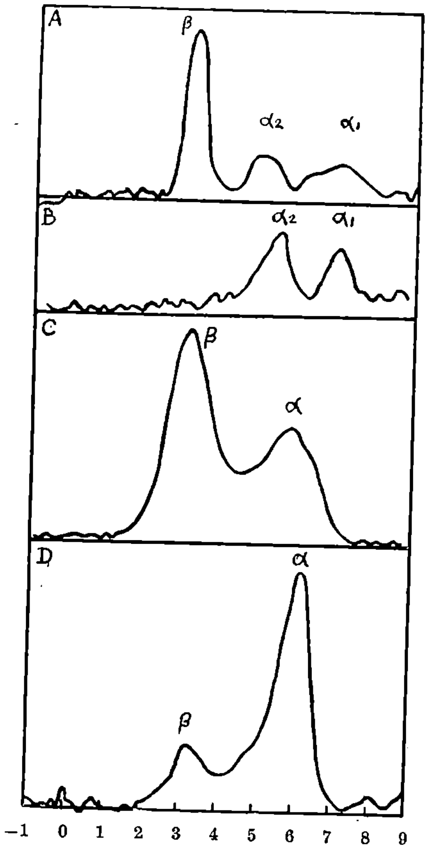

Fig. 1. Electrophoretic patterns of: *A*, unfractionated goat casein; *B*, α goat casein; *C*, unfractionated goat casein after treatment with alcohol and ether; *D*, unfractionated cow casein

are shown in Fig. 1. The patterns of undried freshly prepared unfractionated casein and of α-casein showed the complete separation of the α_1 and α_2 peaks (Fig. 1,*A* and *B*). However, after drying the caseins with alcohol and ether (the usual procedure for preparing them for storage), this separation no longer occurred (Fig. 1,*C*). The drying procedure presumably led to denaturation and thus to an aggregation of the α_1- and α_2-components which was irreversible, at least under the conditions of the experiment. This was borne out by a quantitative evaluation of the scanning patterns. The results are shown in Table 1. The dried casein contained approximately 42 per cent of the α- and 58 per cent of the β-compound, while the fresh unfractionated casein contained about equal amounts of the α_1- and α_2-components and 60 per cent β-casein. The relative amounts of the α- and the β-fractions were slightly different from those found by Dovey and Campbell[2], namely, 40 per cent α and 60 per cent β as against 49 per cent α and 51 per cent β.

Freshly prepared α-casein from cow milk did not show this separation into two components under a variety of conditions of *p*H, buffer concentration and voltage gradient, although it is known to be inhomogeneous[1]. A scanning pattern of a typical experiment with unfractionated cow casein is included in the figure for comparison (Fig. 1,*D*). It shows that the mobility of the cow α-casein was intermediate between those of the goat α_1 and α_2 fractions, while the mobility of the β-caseins was approximately the same. This latter result is in agreement with the findings of Dovey and Campbell[2]. The quantitative distribution of the α- and β-components of cow casein agrees reasonably well with that found by other authors.

Table 1. Electrophoretic Distribution of Cow and Goat Casein (in per cent Total Protein)

Casein	α_1	α_2	β
Goat unfractionated fresh	18·6	20·9	60·4
Goat α fresh	47–49	51–53	—
Goat unfractionated dried	42		58
Cow unfractionated fresh	78		22

The distribution of the various components in the cow and goat caseins is quite different. While Waugh and von Hippel[1] found that cow casein consists of 55 per cent α-casein, 30 per cent β-casein and 15 per cent *k*-casein the present results for the goat protein show the presence of 19 per cent α_1-casein, 21 per cent α_2-casein and 60 per cent β-casein. It is hoped in further experiments to compare some of the chemical and physical properties of the various components of the caseins from the two species.

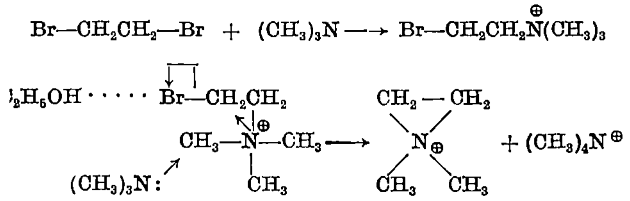
Reaction of Ethylene Bromide with Trimethylamine and the Neuromuscular Blocking Activity of Ethylene*bis*-(Trimethylammonium)

Although the neuromuscular blocking properties of alkylene*bis*-(trimethylammonium) salts have been much studied since the important, simultaneous reports of Barlow and Ing[1] and of Paton and Zaimis[2], the relative potency of ethylene*bis*-(trimethylammonium) (I) appears to have remained doubtful. In brief, I-dibromide, prepared by the reaction of ethylene bromide with trimethylamine, was reported to have unusually high activity comparable to that of tetramethylammonium (II)[1,3,4]. This was most remarkable in that the C_3, C_4 and C_5 *bis* salts were found to be almost inert. On the other hand, I-diiodide, prepared from ethylenediamine and methyl iodide[5], was reported to display only a weak action, like that of its immediate *bis*-quaternary homologues[2].

It appeared probable to us that the source of the confusion was the chemical identity of the ethylene*bis*-(trimethylammonium) tested. In particular, the reaction of ethylene bromide with trimethylamine has long been known[6] to produce a mixture of salt products. Moreover, neither Barlow and Ing[1] nor Schueler[3] (whose salt was used by Thesleff and Unna[4]) reported acceptable analytical data for the I-dibromide prepared by this method. It was therefore deemed of value to pursue this question further.

Essentially as described[1], an ethanol solution of ethylene bromide and excess trimethylamine contained in a pressure bottle was heated for 12 hr. at 80° to yield a mixture of salt products, purifiable only with difficulty. Repeated fractional crystallization afforded fractions with ionic bromine contents ranging from 43 to 62 per cent. A fraction corresponding most closely with that obtained by Barlow and Ing was selected for study. It soon became evident that this material was not I-dibromide, but was apparently tetramethylammonium (II)-bromide. Barlow and Ing reported no m.p. below 280° for their material. Our salt did not melt below 360° (copper block). In agreement with Lawson and Collie[7], authentic II-bromide likewise did not melt below 360°. Found: C, 31·55; H, 7·81; Br (ionic), 51·23, 51·46. Found (Barlow and Ing[1]): C, 31·5; H, 7·9. $C_4H_{12}BrN$ (II-bromide) requires: C, 31·18; H, 7·85; Br, 51·88. On the other hand, $C_8H_{22}Br_2N_2$ (I-dibromide) would have required: C, 31·38; H, 7·25; Br, 52·21. It thus appears that Barlow and Ing's salt and, no doubt, Schueler's salt as well, was actually II-bromide rather than I-dibromide, which would explain the published results.

The II-bromide could have arisen *via* a transmethylation process, for example:



$$Br{-}CH_2CH_2{-}Br + (CH_3)_3N \longrightarrow Br{-}CH_2CH_2\overset{\oplus}{N}(CH_3)_3$$

The dimethylethylenammonium salt presumed to be formed in this reaction would, of course, react further to give other products.

Authentic ethylene*bis*-(trimethylammonium) diiodide was obtained by a two-step process. Exhaustive methylation of ethylenediamine by the Eschweiler–Clarke method afforded ethylene*bis*-(dimethylamine), b.p. 120–122° (lit. b.p. 121–121·5°). This, with excess methyl iodide in *iso*propyl alcohol solution in a pressure bottle, heated for 8 hr. at 75°, and the resultant precipitate washed with acetone and twice recrystallized from methanol, yielded 66 per cent of I-diiodide, decomposing with gas evolution at 282° (lit.[5] 265° dec.). Found: C, 24·28; H, 5·23; I (ionic), 62·96. $C_8H_{22}I_2N_2$ requires: C, 24·01; H, 5·55; I, 63·44.

Neuromuscular blocking activities were determined on these and related salts in order finally to resolve the question. Tetramethylammonium bromide and decamethonium bromide were obtained from commercial sources. The other bromide salts were analytically pure samples prepared by standard procedures.

The compounds were tested in mice using the inclined screen procedure of Thompson[8], as modified by Hoppe[9]. 50–80 mice, run in groups of 5, were used for each determination (*ED*50 and *LD*50). Those mice which became paralysed and slid off the screen within 20 min. after the intravenous administration of the test compound were considered positive reactors for calculating the *ED*50. The *LD*50 values were calculated on the basis of deaths occurring within a 24-hr. period. The *ED*50 and *LD*50 values were calculated by the method of Behrens[10].

It can be seen from Table 1 that the Barlow and Ing salt (2*x*) has indeed high neuromuscular blocking activity comparable to that of tetramethylammonium (II). The fact that 2*x* seems to be roughly 50 per cent less effective suggests, perhaps not surprisingly, that it may not be quite pure II. Authentic C_2 salt, however, has less than one-tenth the activity of 2*x* and, in approximate agreement with Paton and Zaimis[2], is a relatively weak agent of the same order of potency as its immediate homologues.

Table 1. COMPARISON OF INTRAVENOUS *LD*50 AND *ED*50 VALUES OF POLYMETHYLENE-*bis*-(TRIMETHYLAMMONIUM) SALTS,

$(CH_3)_3N^+{-}(CH_2)_n{-}\overset{+}{N}(CH_3)_3.$
(Results in terms of cation weight)

n	2	2*x**	3	4	6	10	II†
*LD*50	21·7	0·99	42·5	73·8	10·5	0·46	0·79
*ED*50	4·9	0·46	19·0	33·5	7·25	0·17	0·31

* The material comparable to that of Barlow and Ing (ref. 1), that is, tetramethylammonium.

† Authentic tetramethylammonium.

Mention should be made of the very poor quantitative correlation between our mouse data for the C_3–C_6 salts and that previously reported[3,4]. This may possibly be ascribed to differences in experimental techniques. The present results indicate that activity diminishes in a gradual, orderly fashion in going from the C_2 to the C_3 to the C_4 salt and that there is a minimum in activity at C_4. With the premise that a primary factor in neuromuscular blocking efficacy is a favourable lipophilic–hydrophilic balance in the *bis*-quaternary ammonium cation[11], this behaviour could be a result of increased interaction between juxtaposed charged nitrogens. As the linking chain is shortened from C_4 to C_3 to C_2, the cationic groups act progressively less like two independent ions and approach, in effective physicochemical behaviour, a single doubly-charged ion in a single solvent cage; it is suggested that this effect more than counterbalances the concomitant (disadvantageous) loss in lipophilic bulk.

We are grateful to Dr. C. J. Cavallito for his interest in and criticisms of this work.

Activation of a Permeability Factor in Plasma by Contact with Glass

IT has been shown previously that contact of blood plasma with glass and with certain other surfaces leads to the formation of an unstable substance which accelerates coagulation[1]. This reaction was found to be similar to the production of a uterus-stimulating and pain-producing substance by glass contact[2]. Subsequent work showed that both these changes are induced by a common initial reaction in which an inactive precursor is converted into an active agent referred to as the 'contact factor'[3]. The purpose of the present communication is to demonstrate that yet another biological activity is induced in cell-free plasma or serum by contact with glass. The investigation was suggested by the work of Miles and Wilhelm, who found that a substance which increases capillary permeability (permeability factor) is formed when plasma or serum is diluted with physiological saline[4].

Blood was obtained from guinea pigs by cardiac puncture under ether anæsthesia. Cell-free, citrated plasma was obtained by the method previously described[1]. Cell-free serum was prepared as follows: blood collected into chilled tubes was centrifuged at 3,000 r.p.m. for 30 min. at 0° C. The upper two-thirds of the plasma were carefully removed and allowed to clot at 37° in siliconed tubes, the successive crops of fibrin being removed with a wooden applicator. The resulting serum was mixed with 20 per cent trisodium citrate (0·2 ml./5 ml. serum). Throughout all operations involving the collection of blood, contact of plasma and serum with glass was avoided by using siliconed apparatus. The samples were activated by rotation with an equal weight of glass 'ballotini' (surface area 200 cm.^{2}/gm.) and tested without delay. Permeability experiments were conducted according to methods of Miles and Wilhelm[4]: albino guinea pigs were 'blued' by intravenous injection of pontamine blue (50–70 mgm./kgm.) and injected intradermally with 0·1 ml. amounts of the test preparations. The degree of induced permeability was assessed by measuring the diameter and estimating the intensity of blueing around the site of injections 8–10 min. after administration of the test substances.

In most of the guinea pigs samples of plasma or serum which had not been in contact with glass produced only slight blueing, 1–4 mm. in diameter. A small proportion of animals showed a more intense reaction with homologous, but not with autologous, samples. This was, presumably, due to individual incompatibility and these animals were not further used. Samples exposed to glass ballotini produced an area of moderate to intense blueing 6–10 mm. in diameter which began to appear within 3 min. of injection and reached maximal intensity within 10 min. Serum was usually more effective than plasma. The greatest effect was obtained after approximately 2 min. contact with glass. Removal of the ballotini at this time was followed by a rapid decay of activity which fell to pre-activation level within a further 3–5 min. This instability made it necessary to test the glass-treated samples with the minimum of delay. Continued exposure to glass led to the complete and irreversible exhaustion of activity within 20 min. (Table 1, Fig. 1). When plasma or serum were pre-heated at 56° for 20 min. activation was not affected but decay and exhaustion were slowed. Heating above 60° prevented activation by glass. Adsorption with aluminium hydroxide produced no change in response (Fig. 1). The reaction did not occur if soybean trypsin inhibitor (Light and Co., conc. 1 mgm./ml.) was added before or immediately after contact with glass.

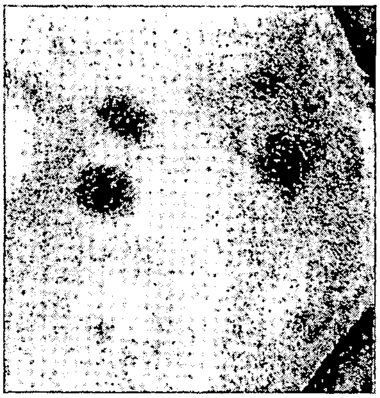

Fig. 1. Effect of citrated serum on permeability: Left, non-adsorbed; right, adsorbed with aluminium hydroxide. Glass contact, from top to bottom: 0 min., 2 min., 20 min. Photographed 20 min. after injections

Table 1. Effect of Glass Contact on the Permeability-inducing Action of Citrated Serum (Results Read 8 min. after Each Administration)

Treatment of serum samples	Diameter and intensity of blueing	
Glass, 0 min.	2 mm.	(+)
Glass, 2 min.	8 mm.	(++)
Glass, 2 min., then silicone, 4 min.	2 mm.	(+)
Glass, 10 min.	5 mm.	(+)
Glass, 20 min.	3 mm.	(±)

These observations are very similar to those on the initiation of clotting and the formation of pain-producing substance. They suggest that the agent which induces permeability is activated by the same, or a very similar, mechanism. The relation between the permeability factor which is activated by glass on one hand and by dilution on the other is not yet clear. We know that dilution of plasma also accelerates clotting[5] and liberates a pharmacologically active substance similar to pain-producing substance[6]. It may therefore be significant that, after the plasma has been exhausted by contact with glass, its dilution no longer leads to the formation of uterus-stimulating substance (unpublished observations). This suggests that contact with glass and dilution may act on the same plasma components.

I am indebted to Prof. C. A. Keele and Prof. A. A. Miles for their kind help and advice, to Dr. G. S. Dawes for the facilities at the Nuffield Institute, where this work was begun, and to Mr. J. Charles for technical assistance. The work was supported by a research grant from the Royal Australasian College of Physicians.

α-Picoline from *Rumex obtusifolius* L.

α-Picoline has been isolated from the leaves of the dock, *Rumex obtusifolius* L. There are isolated instances where pyridine and simple derivatives have been found to occur in Nature, for example, pyridine in *Aplopappus hartwegi*[1] and 3-methoxypyridine in *Equisetum arvense*[2]. This would appear to be the first record of the presence of α-picoline in a natural source. The base was isolated in 0·1 per cent yield from an aqueous extract of the leaves and characterized as its hydrochloride (m.p. 200° anhydrous), picrate (m.p. 165–166°) and methiodide (m.p. 226–227°).

Interaction of Hormone and Photoperiod in an Early Variety of Rice

THE interaction of hormone and photoperiod has been studied in cocklebur[1-5], Biloxi soybean[5] and Orchad grass[6]. In the present investigation the effect of the hormones in relation to photoperiodism has been studied in an early variety of rice, *N*136, which has been found to be intermediate in its photoperiodic behaviour[7]. Graded seeds of this pure strain were soaked on December 10, 1956, with 500 p.p.m. of the three plant-growth substances, β-indolylacetic acid (IAA), α-naphthylacetic acid (NAA) and 2,3,5-tri-iodobenzoic acid (TIBA), for 72 hr., a treatment which was found to be effective in earlier studies[8,9]. The grains were next thoroughly washed in water and sown in earthenware pots containing a mixture of loamy garden soil and cow-dung manure. The pots were divided into two series. In series 1 the plants simply grew after the initial hormone seed-treatment. In series 2 the plants also received an 8-hr. photoperiod (6 a.m.–2 p.m.) from the twenty-first day until panicle emergence. Two other series of unsoaked seeds were used. In series 3 the plants were given the short photoperiod as in series 2. In series 4, plants remained as untreated controls. The results are shown in Tables 1 and 2.

Table 1. LENGTH OF THE VEGETATIVE GROWTH PERIOD AND OTHER CHARACTERISTICS OF VEGETATIVE GROWTH AT THE FINAL STAGE (AVERAGE OF TWENTY-FOUR PLANTS)

Treatment	No. of days to ear emergence	No. of tillers per plant	Total No. of green leaves per plant	No. of leaves on the main shoot	Height per plant (cm.)
Seed soaked with :					
IAA	78·71	5·29	20·58	8·29	69·77
NAA	85·88	6·17	25·25	9·13	63·54
TIBA	82·96	5·58	20·54	8·63	68·35
IAA plus 8-hr. photoperiod	84·58	6·42	29·21	10·29	70·71
NAA plus 8-hr. photoperiod	91·08	9·17	38·88	12·50	65·92
TIBA plus 8-hr. photoperiod	89·04	7·21	30·63	10·92	62·65
8-hr. photoperiod alone	82·75	7·33	27·50	11·08	70·50
Controls	78·25	6·54	23·08	9·50	71·83

Analysis of the data shows that :

(1) Ear emergence was significantly delayed in the plants which were subjected to simple α-naphthylacetic acid treatment, and in those where this was followed by short photoperiod. The delay was more in the latter case than in the former, that is, the effect of the short photoperiod was additive to that of the hormone. Possibly this is due to the formation during the photoperiodic treatment of a substance or substances the influence on flowering of which is similar to that of the hormone itself.

(2) With regard to vegetative growth the plants subjected to the short photoperiod alone showed, in later stages, increased tillering and formed a larger number of leaves, though the elongation of the shoot was not much affected. Where the treatment consisted of only soaking the seed in hormone the plants in general showed less vegetative growth, while where the hormone treatment was supplemented with the short photoperiod the plants treated with α-naphthylacetic acid exhibited the greatest vegetative growth and plants treated with β-indolylacetic acid the least.

(3) Grain yield was significantly higher in plants which were treated simply with β-indolylacetic acid solution and in those which were given the α-naphthylacetic acid treatment plus the short photoperiod. In general, the plants given the short photoperiod exhibited better grain yield than those grown with a natural day-length.

(4) The higher grain yield is due mainly to a larger number of panicles and to a better percentage of grain setting.

We thank the Utkal University for the award of a Government of India Senior Research Scholarship to one of us (G. S.), the Jnan Vijnan Parishad Fund for a grant-in-aid, and Prof. B. Samantarai for providing facilities for carrying out this investigation.

Table 2. GRAIN YIELD AND ITS COMPONENTS

Treatment	Grain yield per plant (gm.)	No. of panicles per plant	Length of panicle (cm.)	No. of spikelets per panicle	No. of grains per panicle	Percentage of grain setting	1,000 grains weight (gm.)
Seed soaked with :							
IAA	2·80	4·33	17·43	74·59	45·30	60·73	14·25

Elimination of Dialysis in the Preparation of Hydrophobic Sols

THE preparation of hydrophobic colloidal solutions by double decomposition, as, for example,

$$\mathrm{AgNO_3 + KI \rightarrow AgI + KNO_3}$$

is greatly complicated by the elaborate process of dialysis necessary to remove the unwanted electrolyte, in this case potassium nitrate. The sols purified by electrodialysis usually contain a considerable quantity of polyvalent ions, drawn from the water used in the dialysis into the colloidal solution. These ionic contaminants are strongly adsorbed to the sol particles and it is often difficult to eliminate them.

The following procedure, tested in our laboratory with good results, avoids the formation of a foreign electrolyte and therefore avoids subsequent dialysis.

A cation exchange resin ('Dowex' 50) was loaded with 200 m.equiv. silver ion by treating the hydrogen-exchange resin with a solution of 200 m.mol. of silver nitrate.

$$R\mathrm{H + AgNO_3 \rightarrow} R\mathrm{Ag + HNO_3}$$

In order to eliminate the electrolyte (nitric acid) the resin was washed several times with distilled water.

Then 1 litre of solution containing 200 m.mol. of potassium iodide was added to the silver resin; at once a colloidal solution of silver iodide was formed.

$$R\mathrm{Ag + KI \rightarrow} R\mathrm{K + AgI}$$

The reaction being complete, a highly concentrated sol (about 200 m.mol. silver iodide/l.) was obtained in one operation.

Conductivity measurements showed that it contains very little electrolyte ($\sigma = 3 \cdot 1 \times 10^{-5}$ ohm^{-1} cm.$^{-1}$), which compares favourably with the degree of purity of electrodialysed sols; the risk of contamination of the sol by polyvalent ions was excluded. The stability of the sols thus prepared was also excellent.

This sol, which we called a potassium sol (the counter-ions of the sol particles are formed by potassium ions), can be converted in a hydrogen sol or a barium sol by sending it over a cation-exchanger saturated with hydrogen or barium ions.

Separation, Detection and Estimation of C21 17 : 20-Dihydroxy-20-methyl-steroids

A NUMBER of C21 steroids characterized by the 17 : 20-dihydroxy-20-methyl side-chain at C17 have been isolated from the urine of normal people[1,2] and from the urine of patients with adrenocortical hyperplasia[3] or adrenocortical tumours[4] (see Table 1). The separation and identification of members of this group of steroids is necessary for the study of their normal and abnormal metabolic formation and excretion; the following is a method which is capable of separating, detecting and estimating quantitatively all such urinary steroids so far isolated.

The known steroids of this series are detectable on dried paper chromatograms using the 70 per cent phosphoric acid test described for pregnane-3α : 17α : 20α-triol-11-one[5] and pregnane-3α : 17α : 20α-triol[8]. The results of the colour test on the 17 : 20-dihydroxy-20-methyl-steroids are shown in Table 1. An approximate estimate of the amounts of such steroids on a paper chromatogram may be obtained from the intensity of the colour or fluorescence and the size of the spots. The relative sensitivity of the colour test for the different steroids is indicated in the table; amounts of up to about ten times the minimum can be judged from the intensity and size of spot.

Some of the compounds in Table 1 have been separated on paper chromatographic systems of the Zaffaroni type[6] (compounds I and V) or the Bush type[2] (compounds I, II, III). Paper chromatographic studies of mixtures of all the steroids I–VI have shown that complete separation of the compounds is possible in a descending chromatogram, run with the solvent system benzene/formamide for 12 hr. on a 35-cm. long Whatman No. 1 paper at 25° C. The rates of movement of the steroids relative to pregnane-3α : 17α : 20α-triol are shown in Table 1. Compounds II and IV move closely together, but under the above conditions separate completely; the largest amounts of each steroid used in these tests corresponded to about 12 μgm./cm. width of paper. Mixed with neutral chloroform extracts, prepared from urine treated with β-glucuronidase preparations for hydrolysis of steroid conjugates, compounds I–VI continued to give satisfactory chromatographs and moved at the same relative rates as were found with the pure steroids.

A general method for the estimation of 17 : 20-dihydroxy-20-methyl-steroids and its application to urinary extracts has been described[7]; this method is based on the formation of acetaldehyde from the C17 side-chain of these steroids ('acetaldehydogenic steroids') when oxidized with periodic acid. As steroids with other C17 side-chains are not estimated and do not interfere in this estimation, it is particularly suitable for the assay of the steroids listed in Table 1, after their separation by paper chromatography. It has been found that this estimation of 'acetaldehydogenic steroids' may be carried out without modification directly on dried portions of paper chromatograms (benzene/formamide system); elution of the steroids from the paper prior to oxidation is not necessary. Amounts of steroid down to about 2 μgm. can be estimated quantitatively on the paper.

Table 1. SEPARATION AND DETECTION OF 17 : 20-DIHYDROXY-20-METHYL STEROIDS

Steroid	Movement of steroid on chromatogram in solvent system benzene/formamide relative to steroid *I* = 1·00	After heating on paper with 70 per cent phosphoric acid		
		Colour in daylight	Fluorescence in ultra-violet light (3660 A.)	Minimum amount clearly detectable (μgm./sq. cm.)
I Pregnane-3α : 17α : 20α-triol	1·00	Purple	Pink	1–2
II Pregnane-3α : 17α : 20β-triol	1·22	Purple	Violet–pink	1–2
III Pregn-5-ene-3β : 17α : 20α-triol	0·91	Purple	Yellow	2–4
IV Allopregnane-3α : 17α : 20α-triol	1·14	Purple	Pink–brown	1–2
V Pregnane-3α : 17α : 20α-triol-11-one	0·24	None	Blue–violet	0·3–0·6
VI Pregnane-3α : 11*B* : 17α : 20α-tetrol	0·1	Purple	Pink	1–2

The above technique provides a complete method for the separation, detection and estimation of the known urinary 17 : 20-dihydroxy-20-methyl-steroids. Use of the method in estimating these steroids and in detecting new compounds in the urine of normal and diseased people will be described in detail elsewhere.

I acknowledge a grant from the New South Wales State Cancer Council, and thank Prof. C. W. Emmens for his interest in this work. Drs. Gallagher and Hirschmann and Prof. G. F. Marrian kindly gave steroids.

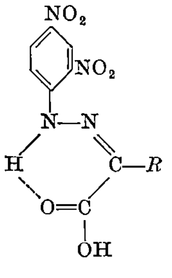
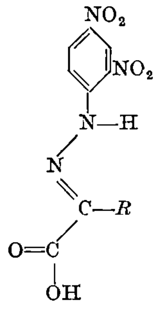
A New Reaction for the Differentiation of *cis*- and *trans*-Isomers of Nitrophenylhydrazones of some α-Keto Acids

RECENTLY, it has been reported by several investigators that there exist *cis*- and *trans*-isomers in 2 : 4-dinitrophenylhydrazones of pyruvic acid[1,2], benzoylformic acid[3] and α-keto-β,β-dimethyl-γ-butyrolactone[4] as shown in (I) and (II) respectively. This was supported by infra-red spectra, since the wave-numbers of the stretching bands of CO and NH of the *cis*-form were smaller than those of the *trans*-form. Our interest in the structures of the isomers of these hydrazones has led us to the discovery of a new chelating reaction, capable of differentiating the two forms.



(I)



(II)

When 0·1 gm. of zinc powder was added to a mixture of 10 μmoles of nickel chloride and 30 μmoles of the *cis*-hydrazone in 5 ml. of 70 per cent aqueous ethanol (the reaction never occurred in absolute alcohol) and shaken for a few minutes, a red colour appeared. This did not happen with the *trans*-hydrazone. Maximum coloration was obtained at a 3 : 1 molar ratio of hydrazone to nickel. No coloration was produced when the nickel chloride solution was added to a hydrazone solution which had been shaken with zinc powder and then filtered to remove the powder. From these facts, the coloration is presumed to result from chelation of nickel with the carboxyl group and with a metastable group produced by the reduction of the nitro group. Nickel was found to be replaceable by cobalt, iron and mercury. These colouring reactions were also observed with several other nitro-compounds (Table 1). The shifts in the value of $\lambda_{\max.}$ on chelation with nickel were as follows. Pyruvic acid 2 : 4-dinitrophenylhydrazone : *cis*, 370 mμ to 380 mμ ; *trans*, 356 mμ to 358 mμ. Benzoylformic acid *o*-nitrophenylhydrazone : *cis*, 425 mμ to 447 mμ ; *trans*, 412 mμ to 365 mμ. The chelated compounds of the *cis*-forms showed more intense absorption in the longer wave-length region than those of the corresponding *trans*-forms.

Table 1. COLOUR REACTIONS WITH SOME NITROPHENYLHYDRAZONES AND NITROPHENOLS

Compounds		Colouring reaction
2 : 4-Dinitrophenylhydrazone of pyruvic acid	*cis*	+
	trans	–
2 : 4-Dinitrophenylhydrazone of benzoylformic acid	*cis*	+
	trans	–
o-Nitrophenylhydrazone of benzoylformic acid	*cis*	+
	trans	–
m-Nitrophenylhydrazone of benzoylformic acid	*cis*	–
	trans	–
p-Nitrophenylhydrazone of benzoylformic acid	*cis*	–
	trans	–
o-Nitrophenol		+
m-Nitrophenol		–
p-Nitrophenol		–

Judging from the results shown in Table 1, the presence of a nitro-group at the *ortho* position in the benzene ring is indispensable for this colour reaction. Furthermore, this colour reaction is confined to α-keto acids, in which the nitro- and carboxyl-groups are situated in positions suitable for chelating around the nickel atom. Thus in the hydrazones of symmetrical keto acids only that of mesoxalic acid (α-keto acid) shows a positive reaction, whereas acetonedicarboxylic acid (β-keto acid) and γ-ketopimelic acid (γ-keto acid) give a negative reaction.

This reaction can be used to differentiate the geometrical isomers of 2 : 4-dinitrophenylhydrazones of α-keto acids, but it is less effective if the hydrazone isomerizes rapidly.

The α-β Transformation in Keratin

BENDIT[1] has recently underlined the necessity for refinement of some of the earlier ideas[2] on the mechanism of the α–β transformation in wool keratin. The problem of a precise quantitative investigation of the transition is difficult, largely because of the intervention of relaxation and creep, the effects of which on the crystalline phases are unknown. Recently[3], a technique for obtaining the desired diffraction data in a short time has been described, and its use, together with standard diffractometric technique, has enabled some interesting preliminary results about the transformation to be obtained.

In view of the importance which knowledge of this mechanism has in a wider context it is thought worth while to record a summary of the conclusions from X-ray and related elastic data. It must be underlined that some of the assumptions on which the deductions are made may be suspect; but in the light of consistent correlationships with other factors they appear quite reasonable.

The following, then, is a tentative summary of the salient features of the transformation, the stretching being carried out in water at 50° C., sufficient time being allowed for relaxation to be nearly complete before the X-ray results were obtained.

A quantitative X-ray investigation of the α–β transformation in Lincoln wool keratin has been made using a Hilger double-beam diffractometer. It is deduced that the reaction proceeds through an intermediate phase β* of less order than either the α or β phases according to the scheme

$$\alpha \rightleftharpoons \beta^* \rightleftharpoons \beta$$

The regions which contribute to stress during the transformation are only slightly perturbed from the crystallographically well ordered.

There is a close correlation between the elastic properties and changes in discrete X-ray diffraction intensities.

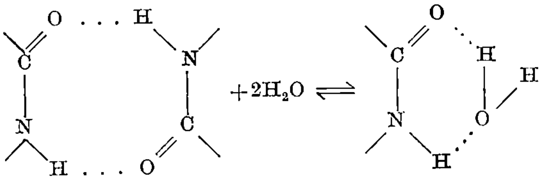
The α phase, representing approximately 60 per cent (linear measure) of the fibre, is in series with a less extensible γ phase, which requires severe disulphide bond fission to enable it to be strained; these phases being those referred to as α and γ keratose elsewhere[4].

It is suggested that the broad diffuse equatorial reflexion about 10 A. is a doublet formed from two reflexions the values of which are 10·7 A. and 9·55 A. The first reflexion is variable and probably relates to the assumed helical structure[5], while the second is invariant and may be caused by the γ keratose.

The extensibility predicted for the α phase (0·88) is in fair agreement with that observed[2] (1·27). The fraction of β material present at an extensibility x is given by

$$\beta = 1{\cdot}225\,x + 0{\cdot}0816$$

The essential feature of the initial change is a hydration effect accompanying chain straightening according to the scheme



Interchain hydrogen bonding is initially absent in the β form but appears after steam-setting and prolonged relaxation. The difference in entropy between the α and β phases is small. The entropy contribution to load deduced from the X-ray data agrees with direct measurements[6]. The difference in energy between the α and β phases is 1·45 kcal. gm.mol.$^{-1}$. Potential barriers of approximately 20 kcal. gm.mol.$^{-1}$ and 260 kcal. gm.mol.$^{-1}$ exist for extensions from ≃ 0–30 and ≃ 30–60 per cent. Both relate to a helical transformation. Above these extensions an exceedingly high barrier must be overcome under normal conditions, due to the necessity to deform the γ phase.

Observations from supercontraction experiments[7] are also compatible with the present phase structure.

An extended account of this investigation is at present being prepared for publication.

Polynuclear Aromatic Compounds in Coal

IN a recent communication, Friedel[1] compared the specific extinction coefficients of coal at two wave-lengths with those of various polynuclear aromatics and found the values for coal (a Pittsburgh vitrain containing 84 per cent carbon) 30–40 times lower than those for the model substances. From these data Friedel concluded that the concentration of polynuclear condensed aromatics in coal is low.

In our opinion, the reason for this great difference lies in the fact that coal is a very complicated mixture of aromatic compounds. The extinction values of the aromatics quoted by Friedel are the peak values of the strongest band in the spectra of single compounds. The extinction at wave-lengths off the peak is often 10–100 times smaller, so that in a complicated mixture in which all the components have bands at different wave-lengths the average specific extinction coefficient is much below the peak values for the single components. The spectrum gradually loses its band structure as the mixture becomes more complicated. The specific extinction of these complicated mixtures at a certain wave-length will depend mainly on the average number of condensed aromatic rings per molecule.

We compared Friedel's results on Pittsburgh coal with the absorption values of a mixture of twenty-three polynuclear aromatic compounds and of two pitch fractions. The specific extinction coefficients K (in litre/gm. cm.) for the two wave-lengths quoted in ref. 1 are stated in Table 1.

The mixture was prepared by mixing equal amounts by weight of the compounds mentioned in Table 2. The average number of aromatic rings per molecule is 4. The spectrum of this dark brown

mull was taken in a cyclohexane solution at a concentration of 0·1 and 0·01 gm./l. (Fig. 1).

The pitch fractions were prepared in our laboratory by Mr. F. J. Huntjens by fractional precipitation from a chlorobenzene solution with petroleum ether. The ebullioscopic average molecular weights M are listed in Table 1. The spectrum of the low molecular weight fraction was taken in a n-heptane solution, that of the high molecular weight fraction in a benzene solution, both solvents containing 0·3 per cent by volume of pyridine. In both cases the concentration was about 0·01 gm./l. (see the spectra, Fig. 1).

The number of aromatic rings per structural unit was determined by refractometric constitution analysis[2]. The number of aromatic rings for the coal sample is that of a pure vitrinite with the carbon content as mentioned[3].

The peak values of the model substances used by Friedel for the wave-lengths 4000 and 4920 A. are also included in Table 1.

From the collected data it is seen that in the 4000–5000 A. region the specific extinction of coal is in good agreement both with those of the two pitch fractions and with that of the mixture of polynuclear aromatics, all having a comparable number of aromatic rings per structural unit or per molecule.

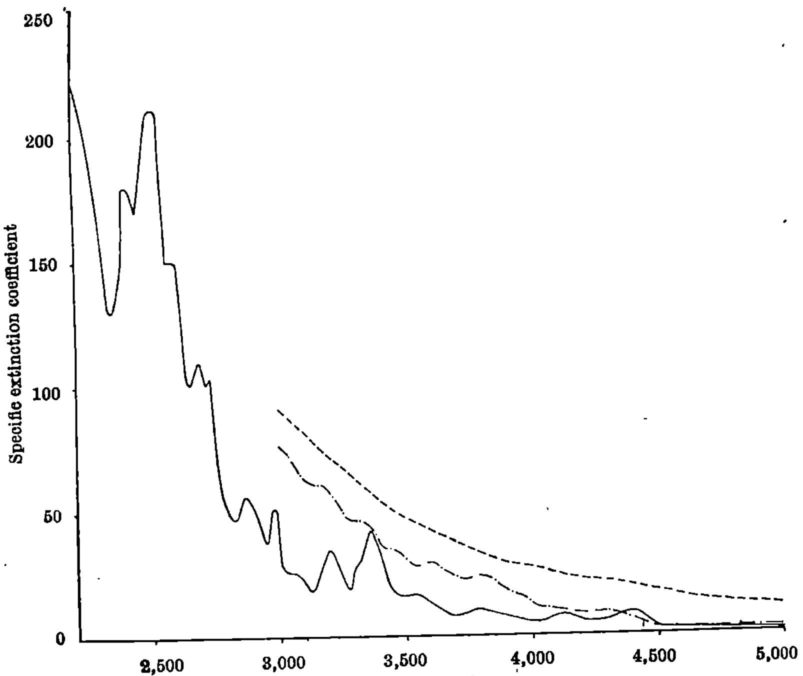

Fig. 1. Ultra-violet spectra of two pitch fractions and a mixture of aromatic compounds. - - -, Pitch fraction $M = 587$; —·—, pitch fraction $M = 249$; ——, mixture of 23 aromatic compounds (see Table 2)

On the other hand, it may be anticipated that a complicated mixture of 9-ring aromatics (such as violanthrene) will have a higher extinction at 4920 A. However, such a mixture should not be compared with a coal sample having only 5–6 rings per unit, corresponding to a carbon content of 84 per cent.

Therefore, it must be concluded that Friedel's extinction data provide no evidence for a low content of polynuclear aromatics in coal.

Identification of *M*-Regions on the Sun

FROM observations of magnetic disturbances on the Earth, Bartels[1] suggested the existence of M-regions on the Sun. Attempts have been made to associate these M-regions with other solar phenomena. Allen[2] tried to show that coronal streams and M-regions are identical; he also concluded that M-regions avoid spot groups or are even destroyed by them. This conclusion was implicitly modified by the results of Denisse[3] and Becker[4]. Identification of M-regions with regions of unusually weak corona emission was recently suggested by Bell and Glazer[5]. Kiepenheuer[6] arrived at the conclusion that filaments are the possible source of M-disturbances. As a result of measurements of the solar magnetic field, Babcock and Babcock[7] believed that the observed unipolar magnetic regions are M-regions. With these measurements M-regions may have ceased to be hypothetical in character. Whether or not this is so, it is still of interest to continue the study of M-regions relative to other solar phenomena.

I have investigated M-regions in their relationship to sunspots. A phase lag method was used. It consists of the analysis of cross-correlograms obtained from daily values of the final Zurich sunspot number Z and the planetary K-index, ΣK_p. Both variables are known to have a pronounced periodicity due to the rotation of the Sun. With certain assumptions regarding constant mean time of travel of particles and a prevalence of their radial emission from the Sun, the phase lag between Z and ΣK_p data can be interpreted in terms of a displacement in solar longitude between Z- and M-regions.

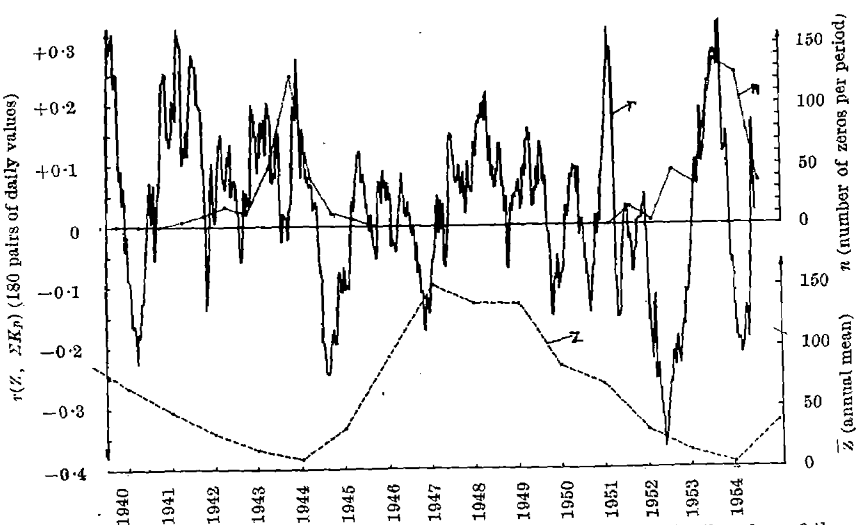

Fig. 1. Variations during the sunspot cycle of the correlation coefficient r of daily values of the geomagnetic index ΣK_p and the final Zurich sunspot number Z with six-month correlation intervals

Correlation intervals of six months were chosen. The period between 1940 and 1954 was investigated by obtaining successively overlapping correlation coefficients r in ten-day steps. The r-distribution throughout this period is shown in Fig. 1. Values are positive as well as negative. Neglecting for the moment that one is dealing with time series and not with randomly selected pairs, each value of r is determined by the 'true' correlation between the variables and by the trend due to their periodicity. The latter contribution is in principle invariant to displacements which are multiples of the period of synodic rotation. A reliable interpretation of the variations of r with the sunspot cycle, as shown in Fig. 1, is therefore difficult. This difficulty is also amplified by the questionable validity of tests of significance for correlation coefficients between time series. It is possible, however, to study the phase relationship between the variables involved. In this case considerations of statistical significance can be circumvented by obtaining cross-correlograms and selecting those which are regular so that the locus of r is a smooth and periodic curve. Z-data were therefore made to lag with respect to ΣK_p-data from -10 to $+35$ days in one-day steps. 558 such cross-correlograms were obtained. Their periodic regularity was a necessary but not sufficient condition for the interpretation of the phase lag as given by the position of the maximum of r in terms of the longitudinal displacement of M-regions and sunspots. Ascertaining that the position of the maximum of r is not attributed to few extreme values of Z and ΣK_p, cross-correlograms of running means of five were used for comparison. They revealed much larger magnitudes of r. Provided the previous distributions of r were regular, the identical displacements of the maxima of r were considered further evidence for a significant determination of the longitudinal displacement between sunspots and M-regions. Additional confirmation for a valid interpretation was found in the variations of the solar rotational period during the sunspot cycle. The results seemed consistent with the knowledge of the latter dependence upon latitude and the latitude shifts of spots with the sunspot cycle.

Fig. 2 shows the relative positions of M-regions and sunspots as obtained by this method. Sunspots are at a fixed position of relative zero longitude assuming the mean time of travel of particles to be zero. If they require 1½ days for their passage from Sun to Earth, the indicated sunspot position is to be displaced in a clockwise sense by about 20° of solar longitude. Each dot indicates a mean position of an M-region. They seem randomly arranged relative to sunspots. This leads one to believe in the existence of two causative mechanisms. The indication of an accumulation of M-regions antipodal to spots can perhaps be attributed to the latter destroying the former.

If other solar data like corona, filaments, etc., are studied in the same manner, a further contribution to the identification of M-regions can be expected.

Dependence of Heat Capacity on Thermal History

IN a recent communication, Morfee and Staveley[1] have reported a "phenomenon for which, as far as we are aware, there is no precedent", namely, that the specific heat of potassium stannichloride appears to be dependent on its previous thermal history. We would like to point out that such a phenomenon has been observed in the metal cerium, where the pronounced peak in the atomic heat[2,3] at 13° K. increases after repeated coolings and eventually reaches a reproducible value about 70 per cent greater than the original. The low-temperature magnetic susceptibility[4] increases by a correspondingly large amount, while both properties show large thermal hysteresis effects between 40° K. and 200° K., which are also dependent on the previous history of the sample. These results can be explained in terms of an incomplete electronic transition $4f \rightleftarrows 5d$. Such behaviour is probably characteristic of systems which are not in true thermodynamic equilibrium.

Mean Free Path of Phonons in a Lead Crystal

THE high flux of 'cold' neutrons now obtainable using the liquid hydrogen source[1], in the Harwell pile BEPO, has been used to investigate the mean free path of phonons in a lead crystal from observation of the spectrum of inelastically scattered neutrons.

In order to evaluate the relations between the incident and scattered wave-numbers set by the conditions of conservation of momentum and energy, a model of the crystal was assumed in which the velocity of propagation of transverse and longitudinal waves is independent of direction. If effects arising from the elastic anisotropy are not important this model is satisfactory for phonon wave vectors small compared with the maximum in the crystal. The experiment was arranged so that this latter condition was fulfilled. The calculations made for the case of the incident wave vector parallel to the reciprocal lattice vector of the (111) plane of lead, and assuming a long mean free path for the phonons, are shown in Figs. 1 and 2. The only process considered is that in which neutrons lose energy in exciting a single phonon. For the crystal orientation chosen and a range of incident neutron wave numbers from 0·9 to 1·4 A.$^{-1}$ the outgoing neutrons have wave-numbers of about 0·4 A.$^{-1}$ for transverse waves, and 0·2 A.$^{-1}$ for longitudinal waves in the crystal, if the scattering angle is about 140°. In addition, it is found that the cross-section for scattering at 140° by transverse waves is much greater than for longitudinal waves. Thus we should see a sharp peak in the spectrum of scattered neutrons at about 0·4 A.$^{-1}$ if the phonon mean free path is long, or a broad peak if it is short.

A beam of cold neutrons having wave-numbers between 0·8 and 1·5 A.$^{-1}$ was modulated by a chopper device and allowed to fall on a single crystal of lead oriented in the way described above. The time-of-flight of neutrons scattered through an angle of 140° was measured over a 70-cm. flight path. The background of the detector was regularly determined by raising the crystal above the neutron beam. The spectrum of scattered neutrons obtained with the crystal at a temperature of 80° K. is shown in Fig. 3. $N(E)$ represents the scattered neutron intensity per unit energy interval; probable errors are indicated.

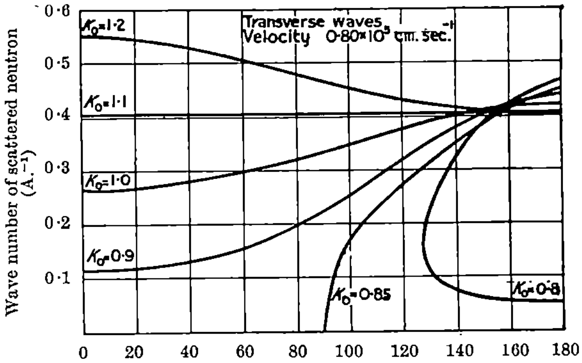

Fig. 1. Calculated values of the wave-numbers of neutrons scattered through given angles after excitation of a single transverse phonon. The orientation of the incident wave-number K_0 (expressed in units of A.$^{-1}$) is described in the text

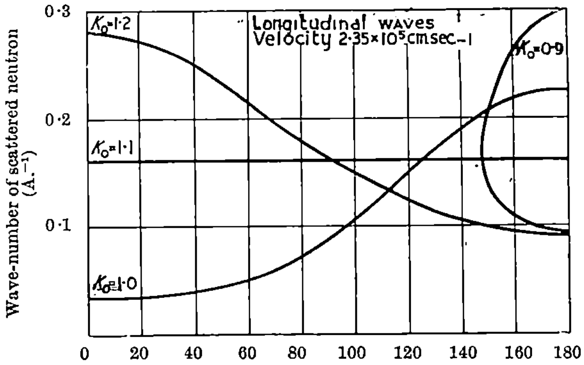

Fig. 2. Calculated values of the wave-numbers of neutrons scattered through given angles after excitation of a single longitudinal phonon

As expected, there is a group of neutrons of wave-number 0·4 A.$^{-1}$ (corresponding to 0·2 mV.); these are neutrons which have lost energy in exciting transverse phonons. The high-energy peak is due to neutrons which have been elastically scattered or have gained energy by phonon absorption. The width of the group of neutrons which have lost energy is of the order of the resolution width of the apparatus, which is about 0·06 mV. This implies that anisotropic effects have not substantially broadened the cross-over region shown in Fig. 1, and so from this value of the width the phonon mean free path at 80° K. is calculated to be greater than 180 A. The average energy of the phonon de-excited in the interaction is approximately 1·5 mV.

The results obtained with the crystal at a temperature of 300° K. are shown in Fig. 4. The ordinate scales in Figs. 3 and 4 are in the same ratio as the inelastic cross-sections (calculated for mean energy gain) at the two temperatures. The number of neutrons which gained energy was found to have increased by this ratio, which is readily calculated[2], while the number in the energy-loss group increased by only one-third the expected amount. This discrepancy cannot be explained by, for example, the increase of multiphonon processes at the higher temperature, and therefore implies that the energy loss group has a greater width at room temperature than at low temperature. The estimated width of about 0·1 mV. at 300° K. corresponds to a mean free path for transverse phonons of 110 A. R. J. Elliott has

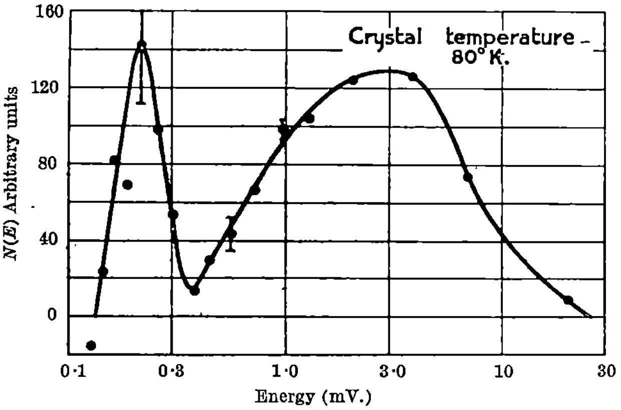

Fig. 3. Observed spectrum of neutrons scattered through an angle of 140° ; crystal temperature, 80° K.

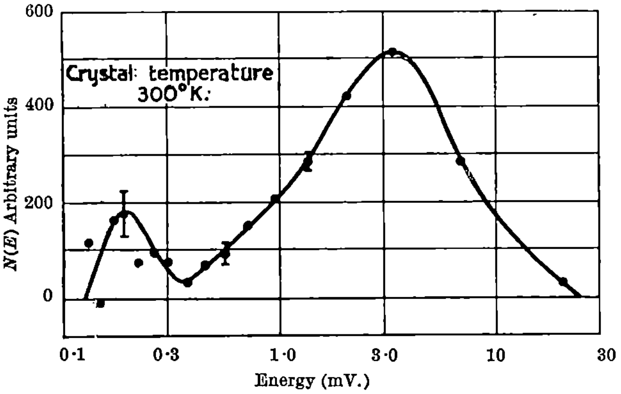

Fig. 4. Observed spectrum of neutrons scattered through an angle of 140° ; crystal temperature, 300° K.

estimated (private communication) that a mean free path of this magnitude is expected from phonon–phonon interactions in lead at room temperatures. It is hoped that ultimately measurements of the mean free path for phonons will be correlated with the thermal conductivity of the crystal.

A useful result is obtained indirectly from the variation with temperature of the scattering cross-section. This allows one to estimate the incoherent elastic scattering cross-section of lead. The value obtained is 0·05 ± 0·03 barns, which is better than previous measurements[3].

This work was performed while one of us (G. J. M.) was seconded to the Atomic Energy Research Establishment, Harwell, from the New Zealand Department of Scientific and Industrial Research. We wish to thank T. L. Schofield, L. V. Lewis and B. E. Hasler for assistance in operating the equipment during the course of the experiment. Miss B. Wilkinson and Miss M. McQuhae assisted in computation and R. O. Ridley and D. Brown kindly provided the lead crystal.

Magnetic Susceptibility of the Alloy Pt_3Fe between 20 and 900 Degrees Absolute

According to the phase diagram published by Kussmann and von Rittberg[1], iron dissolves in solid solution in platinum up to at least 35 atomic per cent of iron. The structure is face-centred cubic, but at compositions around 25 atomic per cent of iron (Pt_3Fe) a superlattice develops which is stable up to temperatures probably in the range 650–800° C.

The magnetic susceptibility of an annealed 25 per cent alloy has been measured between 20° and 900° K. The results are given in Fig. 1. X-ray examination confirmed the presence of the superlattice in a powder taken from this specimen and given the same annealing treatment.

At high temperatures the Curie–Weiss law is obeyed, extrapolating towards a paramagnetic Curie temperature of about −90° K. On cooling below room temperature, deviations from the Curie–Weiss law begin at about 200° K. The susceptibility rises to a distinct maximum at 105° K. and then falls at lower temperatures until about 50° K. where another increase begins.

Susceptibilities were measured in an applied field of 8,200 oersteds. At 290°, 200°, 80° and 20° K. measurements were also made in a range of field strengths between 2,500 and 10,800 oersteds, and no significant variation of the susceptibility with field was detected.

The behaviour observed suggests the existence of antiferromagnetism in the ordered alloy at low temperatures, and further work is in progress to confirm this.

At compositions on either side of 25 per cent of iron, the annealed alloys were found to be ferromagnetic, as was reported by Kussmann and von Rittberg[2]. With decreasing iron-content, the magnetic moment increases, the moment (extrapolated to 0° K.) of the 15 per cent iron alloy being about

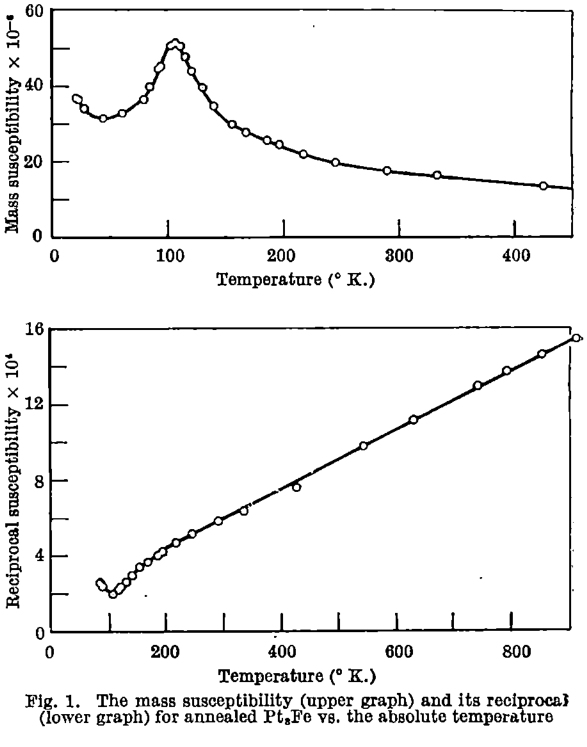

Fig. 1. The mass susceptibility (upper graph) and its reciprocal (lower graph) for annealed Pt_3Fe vs. the absolute temperature

0·6 Bohr magneton per atom. On the other side, the ferromagnetic moment rises more slowly with composition. In the 25 per cent alloy, cold work renders the material quite strongly ferromagnetic. X-ray examination showed that the structure of the cold-worked 25 per cent alloy was still face-centred cubic. The lattice parameter was apparently the same as for the undeformed material, but no superlattice reflexions were observed. It is suggested that the primary effect of the cold work was to destroy the superlattice, and that the disordered state is ferromagnetic. Further work is also in progress on these ferromagnetic platinum-rich alloys.

I wish to thank Prof. W. Sucksmith for his advice and interest, and also the Mond Nickel Company for the loan of the pure platinum on which the alloys are based.

Correlation between Ionizing and Attachment Coefficients and Breakdown Characteristics for Carbon Tetrafluoride

The growth of pre-breakdown currents with distance has been investigated in carbon tetrafluoride for various constant values of E/p (E is the field, p the gas pressure). The purpose of this communication is to give results for ionization and attachment derived from this investigation and to show that they are consistent with previously published[1] breakdown-voltage characteristics for this material in uniform and non-uniform fields. Carbon tetrafluoride is no longer available commercially in Britain and this limited the number of pre-breakdown current measurements.

In electronegative gases the growth of current with distance is given by

$$I = I_0 . \frac{\{\alpha/(\alpha-\eta)\exp(\alpha-\eta)d - \eta/(\alpha-\eta)\}}{1-(\omega/\alpha).(\alpha/\alpha-\eta).\{\exp(\alpha-\eta)d-1\}}$$

where I_0 is the initial current, α the primary ionization coefficient, η the mean number of attachments per centimetre drift in the field direction, (ω/α) a generalized secondary ionization coefficient, and d gap distance. If the Townsend criterion is valid for breakdown in electronegative gases, the threshold for self-maintaining current is obtained when a denominator is zero. On the assumption that secondary processes are small the denominator with increasing values of d, in the range $\eta > \alpha$, approaches zero as $(\eta - \alpha) \rightarrow 0$. In the limit this is a condition which depends upon E only and sets a value for E below which no breakdown should be possible whatever the value of d. Plots of $\log(I/I_0)$ against d for carbon tetrafluoride are not linear and by curve fitting it is possible to determine α and η. Although values of $(\alpha - \eta)$ could be determined to within 1 or 2 per cent, the resolving power of the method was not good enough to permit precise determinations of α and η for the limited number of experiments that could be made.

Fig. 1 gives $(\alpha - \eta)/p$ for various values of E/p, and from the curve the value of $(E/p)_{\alpha=\eta}$ is 47·6 volts/cm./mm. pressure; this value is in close agreement with the experimentally determined limiting value of E/p obtained by plotting E against d for a uniform field at atmosphere pressure.

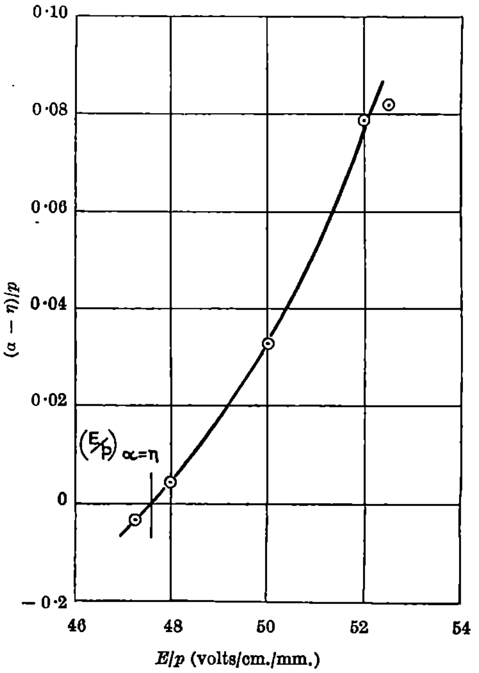

Fig. 1. $(\alpha - \eta)/p$ against E/p in carbon tetrafluoride at a pressure of 230 mm. mercury

For non-uniform fields where the high-stress region is at the positive electrode, the breakdown voltage/pressure curve for electronegative gases rises to a peak value as the pressure increases and then falls until it

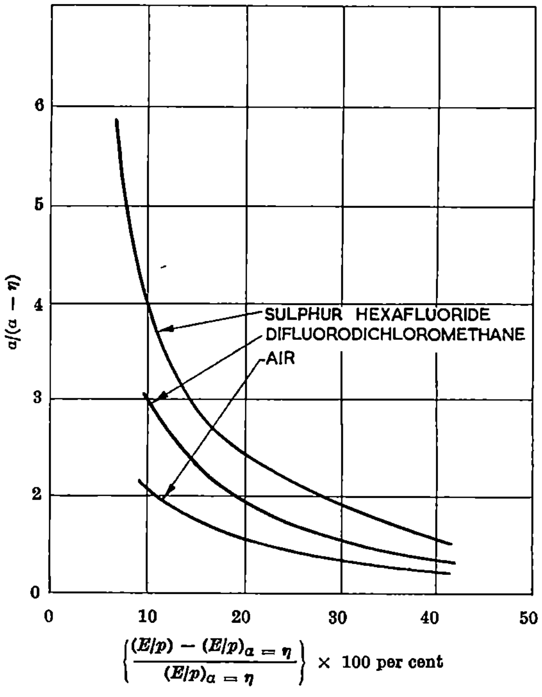

Fig. 2. $\alpha/(\alpha - \eta)$ against field strength expressed as a percentage above $(E/p)_{\alpha=\eta}$

coincides with the voltage for the onset of corona at a critical pressure. Generally, the positive static breakdown voltage is higher than the impulse value below this critical pressure so that field modification involving time is an important factor. It has been argued[2] that with impulses only electrons contribute to the lowering of the field at the highly stressed electrode while with static voltages there is an additional contribution by negative ions. This leads to the conclusion that for any gas at a particular percentage of E/p above $(E/p)_{\alpha=\eta}$ the difference between the impulse and the static values is related to the magnitude of $\alpha/(\alpha-\eta)$. Fig. 2 gives plots of $\alpha/(\alpha-\eta)$ for sulphur hexafluoride, difluorodichloromethane and air against the percentage increase of E/p above $(E/p)_{\alpha=\eta}$; the values for carbon tetrafluoride lie in the region of the curve for air. Experimental data indicate that the difference between the static and impulse breakdown voltage is greater for sulphur hexafluoride than for difluorodichloromethane; for air and carbon tetrafluoride the impulse breakdown voltages exceed by a small amount the static values, possibly due to the effect of time-lags influencing the impulse breakdown.

Periodicity in Sea Roughness and Origin of Microseisms

Various workers have tried measuring the roughness of the sea by observing wave heights at a particular position as well as by compiling wave profiles along large distances by air observations. Glitter photographs of the sea surface have also been statistically analysed for finding the relation between development of wavelets and wind velocity. It has been recognized that description of sea roughness is very difficult by any of the above means. On the other hand, it is well known that radar clutter increases in amplitude with sea roughness, and estimation of sea roughness should be possible by observations of radar clutter. Recently, one aspect of analysis of sea roughness became imperative in view of the hypothesis that microseisms may be caused by means of interaction of wind and sea roughness. According to such ideas, the periods observed in microseisms should correspond to any autocorrelative periods in sea roughness.

A shore-based naval 10-cm. radar was used for the study of radar clutter. The echoes were observed from about 200 ft.^{2} area of sea surface at a certain distance by giving attention only to 1-mm. width at 2,000 yd. range of '*A*' type scan, the angular width of the radar beam being 2½°. The rest of the '*A*' type scan was blocked by black paper. The vertical amplitudes in the narrow width of 1 mm. on the screen gives a record of the intensity of the clutter. These amplitudes were photographed by means of a continuously moving film using a speed of 7·4 in. per min. In the absence of an automatic autocorrelation meter, the amplitudes were read manually at 0·38-sec. intervals and an autocorrelogram was computed. The autocorrelogram showed strong periods of 0·8 sec. and 4·6 sec. There was an indication of a weak period also at 1·2 sec. According to the senior author's hypothesis, periods in sea roughness produce corresponding periods in eddy viscosity at the sea-surface. This causes periodic changes in wind-stress over the sea provided the winds are cyclonic or suitably oriented near a coast line. Such changes cause pulsations in pressure over wide areas at the sea-bottom. On the other hand, according to Longuet-Higgins's theory[2], standing waves, which might be regarded as corresponding to double the period brought out by any sea roughness analysis, cause direct second-order pressure effects of double frequency on the sea bottom. The standing waves of this theory are not likely to be seen always by the usual methods of observation of sea surface. According to the standing-wave theory, simultaneous existence of suitably oriented wind at the originating area in question is not essential.

Refraction of Microseisms

It is well established now that microseisms, the small tremors of varying intensity (in the range of 2–10 sec. period and of the order of a few microns in amplitude) recorded as more or less a permanent background by seismographs, are caused by sea waves associated with cyclonic depressions. The possibility of using these waves for location and tracking of storms has been investigated by many workers, and various techniques for estimating the direction of arrival have been put forward. But as the accuracy of estimation of direction of arrival is improved, corrections have to be applied to allow for the refraction of the waves due to variations in the velocity of propagation along the path from the generating area to the recording station. Microseisms are surface waves of the Rayleigh and Love type, and hence can be affected by variations in the geological structure of the Earth's crust and the changes in ocean depth along the path. While it is very difficult to estimate corrections for the geological configuration of the Earth's crust, the effect due to ocean depth can be calculated.

The effect of coupling between the ocean and the sea bottom on Rayleigh waves has been studied by Stoneley[1], and many workers have calculated the velocity of the modified Rayleigh waves in a uniform elastic sea bed, the ocean being regarded as a homogeneous compressible medium. As the present techniques for the direction of arrival of microseisms consist of using only the Rayleigh wave component, the refraction due to the Stoneley effect can be estimated.

Darbyshire[2,3] used this idea first and constructed refraction diagrams for Bermuda and the British Isles for microseisms arriving from various directions. The wave-fronts were assumed straight and parallel far out in the sea, and successive fronts were drawn at convenient intervals using velocities appropriate to the particular ocean depth. A method of geo-

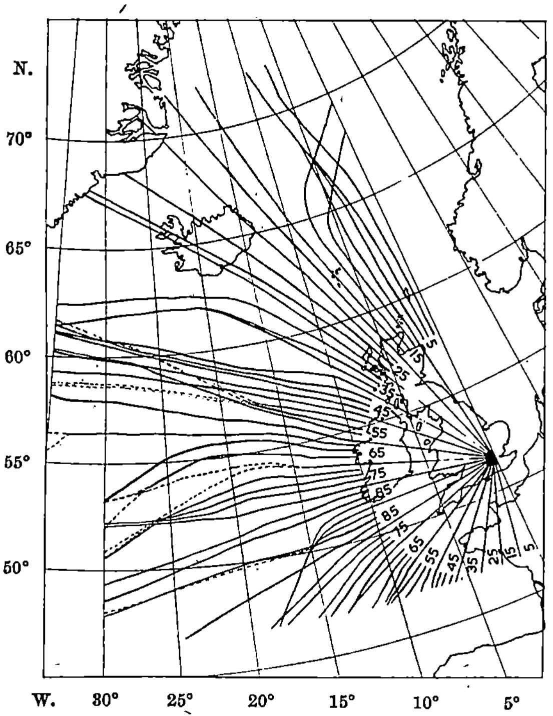

Fig. 1. Refraction diagram for microseisms of 6-sec. period

metrical construction was employed on a bathymetric chart of the area under consideration.

However, for microseisms generated by storms in the deep ocean, the amount of refraction depends on the actual position of the storm with respect to the recording station, and the parallel wave-front theory cannot be applied. Hence new refraction diagrams (Figs. 1 and 2) have been constructed using the reciprocity principle. Rayleigh waves are supposed to originate from the recording station—in this case Kew—and travel outwards. The wave-fronts are circular to start with, but become distorted as the wave progresses through the Atlantic Ocean bed. From these wave-fronts rays are drawn at $2\frac{1}{2}$°-intervals. The diagrams are constructed for 6-sec. and 9-sec. microseisms. The velocity of Stoneley waves for different depths of the oceans was calculated in exactly the same way as Darbyshire did in his paper[2].

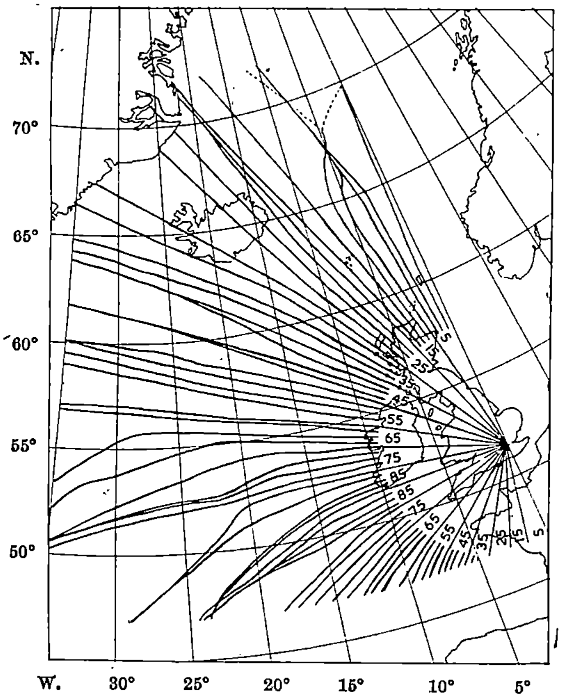

Fig. 2. Refraction diagram for microseisms of 9-sec. period

It is very easy to use these refraction diagrams. Instead of drawing a straight line from the recording station in the computed direction of arrival of microseisms and looking for the source along that line, the ray is followed along the refracted path.

The following are some of the points of interest:

(1) 9-sec. microseisms are refracted less than those of 6-sec. period.

(2) The various focusing and diverging effects are interesting. An example of the former was noticed during the hurricane of September 1957 ("Carrie"). When the storm was in the diverging area south of lat. 50° N. and west of long. 20° W., the intensity of microseisms recorded at Kew was not appreciable. But as soon as it came to the focusing point at lat. 50° N., long. 15° W., there was a sharp rise in intensity which decreased later as the storm crossed over the Irish coast.

(3) The rays represented by the dotted lines in the diagram are due to intersecting wave-fronts and are similar to the double refraction effect in optics.

Many of the anomalies observed by workers in various parts of the world in the measured intensity and direction of arrival of microseisms can, in all probability, be explained by constructing such refraction diagrams. The aid of the 'microseismic barrier' postulated from time to time to explain these anomalies can be reserved for a better use.

Total Sulphydryl Content of Embryos of Arsenic-resistant and -sensitive Strains of the Blue Tick, *Boophilus decoloratus*

The existence of arsenic resistance in the blue tick, *Boophilus decoloratus*, in certain regions of South Africa has been known for 16 years[1]. In a study of this phenomenon, the concentrations of sulphydryl-containing compounds in embryos of the sensitive and resistant strains of this tick have been determined.

The method used for determining —SH containing compounds is an adaptation of Mason's[2,3] method, which is based upon the reduction of ferricyanide ions by thiols to ferrocyanide ions which are then determined colorimetrically as ferric ferrocyanide. Deproteinized extracts of tick eggs at a stage midway between oviposition and hatching were used. Interference by other reducing compounds was eliminated by using a blank in which colour development due to —SH containing compounds was suppressed by addition of formaldehyde prior to addition of ferricyanide.

Fifteen pairs of determinations were carried out using embryos of sensitive and resistant strains of approximately equal age. The sulphydryl content, expressed as per cent —SH radical, of the sensitive strain varied from 120×10^{-5} to $1{,}050 \times 10^{-5}$ per cent (mean $482 \cdot 6 \times 10^{-5}$ per cent) while that of the resistant strain varied from 750×10^{-5} to $1{,}550 \times 10^{-5}$ per cent (mean $983 \cdot 3 \times 10^{-5}$ per cent). The mean difference between the resistant and sensitive members of the pairs was 500·7 in units of 10^{-5} per cent with a standard error of 68·5.

The resistant strain therefore contains slightly more than twice as much —SH radical as the sensitive strain.

Our thanks are due to Mr. D. C. Goch for statistical examination of the results and also to African Explosives and Chemical Industries, Ltd., for permission to publish this communication.

Occurrence of Strains of the Nuclear Polyhedral Virus of the Wattle Bagworm

During the past three years, experiments have been in progress[1] to determine whether the wattle bagworm, *Kotochalia junodi* (Heyl.), could be controlled by artificially increasing the concentration of virus in plantations of black wattle, *Acacia mollissima* Willd., and whether epizootics could be initiated by introducing the virus. In all cases, a high rate of mortality due to polyhedrosis resulted. It was noted, however, that equal concentrations of virus from different localities did not give the same kill; virus suspensions prepared from material collected in plantations remote from those treated consistently gave a higher mortality than those prepared from bagworms from the area in which they were used (Table 1).

Table 1. Effect of Polyhedrosis using: (1) 'Introduced' Virus; (2) 'Local' Virus

(*a*) Mortality per cent five months after treatment

	Treated		Untreated	
	Mean	Range	Mean	Range
(1)	71·9	61·4–79·9	14·6	2·6–18·1
(2)	55·1	46·1–60·5	15·2	9·1–19·9

(*b*) No. of survivors seven months after treatment; only live specimens collected

	Mean No. of bagworms per sample tree	Range	Mean No. of bagworms per sample tree	Range
(1)	0·3	0–2 (18·8)*	27	7–45 (2·7)*
(2)	5·4	1–12 (10·0)*	7	6–9 (3·4)*

(*c*) No. of survivors eleven months after treatment; only mature specimens collected

(1)	0	0	11	3–23†
(2)	4	2–7†	6	5–8†

* Percentage of virus-infected specimens.

† The percentage of virus-infected imagines could not be determined, since mature males emerge approximately four weeks before the females become sexually mature. At the time of collection, only empty pupal cases indicated that mature males had emerged.

These results not only point to a degree of resistance of the bagworm to local virus, but also strongly suggest that there are different strains within the nuclear type of virus found in *K. junodi*.

Dr. K. M. Smith of the Molteno Institute, University of Cambridge, has commented (*in lit.*) upon the development of resistance to virus disease in *Pieris brassicae* L., but this appears to be somewhat different in origin.

A Shorter Microbiological Assay Method for Oxytetracycline and Chlortetracycline

Some organic compounds having a known effect on the growth of bacteria were used for stimulating spore germination and growth intensity of *Bacillus subtilis FDA* 6633, with the view of shortening the length of incubation time when assaying oxytetracycline and chlortetracycline by the cup–plate technique.

The basal medium was made up as follows: agar–agar 45 gm., peptone 7·5 gm., broth 1,500 ml.; *p*H before sterilization 7·0–7·1.

After incubation for a week in a Blake flask the *B. subtilis* spores were washed with sterile, distilled water, heated for 30 min. at 65° C. and centrifuged three times, washing between each centrifugation. To determine the necessary amount (per cent) of spore suspension, its light absorption was measured. The suspension is suitable if its percentage absorption is 80–90 per cent using an orange glass parallel-sided filter with distilled water (Lange, Lichtelelektrisches Kolorimeter, Model IV). 2 ml. of this spore suspension is then diluted with a solution of selected growth factor (in this case, 98 ml. of 0·02 per cent solution of folic acid (pteroylglutamic acid)). 5·5 ml. of the diluted spore suspension is added to 100 ml. melted agar medium and thoroughly but gently stirred with a sterile glass rod. By this method only one layer, 3 mm. thick, was poured out.

The prepared plates were stored in a refrigerator at about + 4° C. for two days. If stored longer, the effect of the growth factor is lost. The working standards and the samples were diluted with phosphate buffer: *p*H 5·0 for oxytetracycline, and *p*H 4·5 for chlortetracycline (*p*H 5·0 buffer: 90·78 gm. potassium dihydrogen phosphate; *p*H 4·5 buffer: 27·20 gm. sodium dihydrogen phosphate, both diluted to 2,000 ml. with sterile distilled water).

After having dispensed the antibiotic in or on the plates, the latter are incubated at 43° C. for 3–4 hr. This incubation time is enough to produce firm bacterial growth, which is easily visible. Inhibition zones are clear, and zone edges are defined. A further advantage is that this microbiological method does not require a special assay procedure or a standard curve.

Of the compounds examined in various concentrations, DL-aspartic acid (0·0014–0·0002 per cent), folic acid (0·0020–0·00002 per cent), indoleacetic acid (0·0014–0·00002 per cent) and lactose (0·02 per cent) promoted spore germination and stimulated growth without disturbing the effect of the antibiotics on bacteria. The growth-stimulating effect of DL-aspartic acid in absence of caramelized glucose seems to be inconsistent with Hachisuka's report[1]. It is possible in this case that the caramelized sucrose components of agar–agar serve as substitute for glucose.

The possibility of employing growth factors to reduce the incubation time opens the way for similar short microbiological assay methods for antibiotics.

Dissemination of *Verticillium albo-atrum* through the Atmosphere

IT is usually considered that spread of disease due to *Verticillium albo-atrum* is either by growth of the pathogen from diseased to healthy susceptible plants by root contact or by the dissemination of infected plant material such as leaves, root stocks, etc. However, the possibility, in some cases, of the disease being spread by airblown spores became apparent when Isaac[1] trapped colonies of *V. albo-atrum* on Petri-dish plates of Dox's agar exposed approximately 2 ft. above a stand of lucerne infected with this pathogen, and also when Davies (unpublished results) isolated *V. albo-atrum* from house dust from Edinburgh and from the atmosphere in a garden in urban London. It should be pointed out that in diseased lucerne plants, even when they are still alive and green, the fungus grows from the vascular tract in the lower basal regions of the stems out into the cortical tissue and from there superficial hyphæ bearing conidia develop ; and it has been shown by Isaac that these conidia will cause infection when placed upon recently cut surfaces of mown, healthy lucerne.

Since this disease is becoming of considerable economic importance, an investigation has been initiated to make quantitative estimates of the number of spores of *V. albo-atrum* in the air, within and above, both diseased and healthy lucerne crops and above meadow land at various sites, namely, Norfolk, Cambridge, Berkshire and Swansea. Efforts were also made to isolate the pathogen from the air near lorries unloading lucerne from an infected crop. The apparatus used to obtain these volumetric determinations was the slit sampler, described by Davies[2], the suction being provided by a hand-operated pump unit similar to that of Gregory[3] except that the pump was driven through gears. For each sample either 50 or 25 l. of air were impacted on to each of a series of plates of Dox's agar in 9-cm. Petri dishes, the intake orifice of the apparatus being 25–26 cm. above ground-level. The results are summarized in Table 1.

Table 1. NUMBER OF COLONIES OF *Verticillium albo-atrum* ISOLATED FROM THE AIR AT EACH SITE

Area	Sampling site	No. of colonies of *V. albo-atrum*	Total vol. (litres) of air sampled
Berkshire	In diseased lucerne crop	6	150
	In healthy lucerne crop	0	150
Cambridge	In mildly infected lucerne crop	1	150
	In healthy lucerne crop	0	150
	Near diseased lucerne straw being turned over	4	150
Norfolk	In diseased lucerne crop	12	150
	In open field 150 yd. down wind from disease crop being mown	12	200
	In "Green shed" of lucerne drying factory	3	50
	In "Green shed" as lorry tipped load of infected lucerne	30–40*	50
Swansea	In diseased lucerne crop	6	180
	In meadow	0	180

* Plate overcrowded with bacteria and yeasts

V. albo-atrum was never isolated alone but developed on plates in competition with the more ubiquitous constituents of the airborne fungal flora such as *Cladosporium*, *Pullularia*, *Penicillium*, *Phoma*, *Mycelia sterilia*, *Sporobolomyces*, yeasts, etc.

The results in Table 1 indicate that the number of spores of *V. albo-atrum* in and above infected stands of lucerne is sufficiently high to suggest that the spread of the disease in this crop may occur by means of wind-blown spores. Further investigations are proceeding along these lines.

The Giant Rat of East Africa

SIX specimens of the giant rat, *Cricetomys gambianus* Waterhouse, one male and five females, were trapped at Amani, a forested area at about 3,000 ft. in the Usambara Mountains of Tanganyika. The rats were trapped in cage-type traps which had been baited with maize. They were killed with chloroform, after which their parasites were removed ; then the rodents were weighed and measured.

Measurements

	Male	Female
Body-weight	1,250 gm.	1,000–1,400 gm.
Head/body	350 mm.	335–380 mm.
Tail	400 ,,	340–400 ,,
Ear	40 ,,	40–45 ,,
Hind foot	75 ,,	70–75 ,,

Mammary formula : 2 – 2 = 8

The only ecto-parasite found on the six specimens of the giant rat was the dermapterous parasite

Hemimerus vosseleri Rehn and Rehn. No fleas, ticks or lice were found. The infestation with *H. vosseleri* varied from 4 to 13 per rat, and included nymphal and adult specimens. In all, 46 specimens of this strange earwig were obtained.

My thanks are due to the Director of Medical Services, Tanganyika, for permission to publish this communication, and to Dr. W. Hincks, of the Commonwealth Institute of Entomology, for his identification of the earwigs.

Seed-coat Structure of Yellow Chinese Rape

Samples have been obtained of seed described as Chinese rape, imported into Europe for oil extraction. The seeds in these commercial samples are either yellow or vinaceous in colour, and the different coloured seeds are to be found in varying proportions. Plants grown from both types of seed corresponded with descriptions of *Brassica campestris chinoleifera* Viehoever[1]. It has not been possible to locate type specimens of the plant in Great Britain.

Comparatively few yellow kinds of cruciferous oil seeds are used commercially[2], and therefore a knowledge of the testa structure of this Chinese seed might well be useful in the analysis of seed samples and oil-cakes.

Fig. 1 is a drawing of a cross-section of the testa. The structure corresponds to that of the rapes rather than the mustards[2]. Consequently, the only other yellow cruciferous oil seed with which one might confuse the Chinese seed is *Brassica campestris* L. var. *Sarson* Prain.

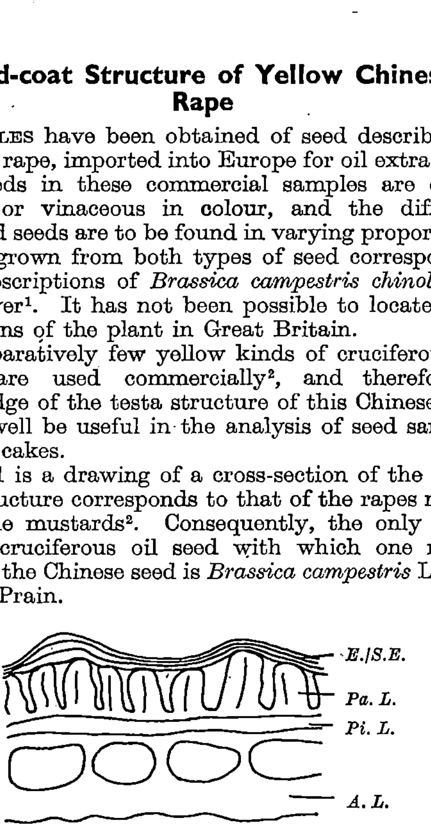

Fig. 1. Drawing of cross-section of testa of yellow Chinese rape (× 400). *E./S.E.*, disorganized epidermis and subepidermis; *Pa. L.*, palisade layer; *Pi. L.*, pigment layer; and *A. L.*, aleurone layer

The testa structure of both species has been compared; but it is extremely difficult to distinguish between the two species on this anatomical feature, although slight inequalities in height of the palisade cells of the Chinese seed present a faint reticulation in surface view. Reticulations are not normally shown by *Brassica campestris* L. var. *Sarson* Prain.

This difficulty of distinguishing between the two species need not present any great problem during the analysis of oil-cakes, because, compared with the mustards, both seeds are usually regarded as fairly mild for feeding purposes.

It is intended to publish the details of this investigation elsewhere. I am indebted to the Incorporated Oil Seed Association and Salamon and Seaber (consulting analytical chemists) for the supply of material and also the Central Research Fund of the University of London for the loan of certain apparatus used in this work.

Nomenclature of Cell Strains

At the International Tissue Culture meeting, held in Glasgow during August 26–27, the subject of the nomenclature of cell-strains used in tissue culture was considered. After general discussion, a committee was appointed and recommendations were made. It was suggested that authors should give the following information when first mentioning a cell strain in the course of a publication. (1) Whether the tissue of origin was normal or neoplastic, and, if neoplastic, whether benign or malignant. (2) Whether the tissue was adult or embryonic. (3) Animal species of origin. (4) Organ of origin. (5) The cell-type (if known). (6) The designation of the strain. (7) Whether the strain has been cloned, and, if so, the clone number. (8) The reference to the original article in which the strain was described.

It was further suggested that the designation of the strain should consist of a series of not more than four letters indicating the laboratory of origin, followed by a series of numbers indicating the strain, for example, *NCL* 123. Thus, a strain might be described: normal adult rat heart fibroblast, strain *XYZ* 111, clone 29 (Lobachevsky, Z. (1922), *J. Metaphys. Cytol.*, **99**, 77). Afterwards, in the same communication it would suffice to refer to the strain by its strain designation.

Histological and Chemical Changes in the Rat Pituitary Neural Lobe following Treatment with Neurohypophysial Substances

No agreement exists as to the effect of administration of exogenous posterior pituitary principles on neurohypophysial structures. Some authors[1] describe no changes in neurosecretory phenomena, others[2] think the dosage important, whereas increase in neurosecretion has been reported by me[3]. One of the difficulties in evaluating and comparing alterations in material stained with chrome-alum hæmatoxylin is the lack of adequate histological assaying methods. When the amount of chrome-alum hæmatoxylin-positive material has not increased considerably following hormone treatment, it is difficult to be reasonably certain of the effect. In addition, not all such material necessarily represents posterior pituitary hormone or 'true' neurosecretory material[3,4].

For these reasons, in the present series of experiments an attempt was made to correlate the histological alterations of the neurohypophysis with changes in chemical composition of the infundibular process, assuming the latter to be a storage place for posterior pituitary principles.

Adult rats of both sexes, body-weight 150–200 gm., were given daily intraperitoneal injections in nine groups of five animals for each experiment, for six consecutive days, using 'Pituitrin' (0·5 U.; 2·0 U.; 2·5 U.), 'Pitocin' (0·5 U.; 1·0 U.; 2·5 U.) or 'Pitressin' (0·5 U.; 2·0 U.; 2·5 U.). The animals were killed on the sixth day 2 hr. after the last injection, and the brain and pituitary gland examined histologically in the usual manner[3]. Sections of control and experimental animals were processed together. It was found that a slight but definite increase in chrome-alum hæmatoxylin-positive material had occurred in the hypothalamic magno-cellular nuclei of all treated groups, independent of the dosage. The infundibular process stained very darkly in all groups, probably more than in normals.

In another series, paper chromatograms (hydrolysis in 25 per cent hydrochloric acid at 110° C. for 18 hr., Schleicher and Schüll paper 2043*b*, butanol/acetic acid, ninhydrin) were made of homogenates of the infundibular process of rats treated similarly ('Pituitrin' 2·5 U.; 'Pitocin' 2·5 U.; 'Pitressin' 2·5 U.). These were compared with chromatograms of neurohypophysis of normal and dehydrated (5 days thirst) animals, brain tissue, and the pituitary principles injected. By standardizing the procedures and running aliquots in doubles in different batches, quantitative as well as qualitative changes could be roughly ascertained. In all groups treated with posterior pituitary principles a marked increase in amino-acid content could be shown, cystine being especially prominent. In the group treated with 'Pitressin' a definite increase in lysine and phenylalanine was observed. From the size and colour intensity of the spots the following quantitative estimates were made: normal, 100; 'Pituitrin'-treated, 145; 'Pitressin'-treated, 185; 'Pitocin'-treated, 160; dehydrated, 75.

It would appear, then, from these results that following treatment with various dosages of neurohypophysial principles there is a definite increase in chrome-alum hæmatoxylin-positive material and amount of posterior pituitary hormones in the rat neurohypophysis. It is not clear whether this increase is due to increased production or decreased release of endogenous neurohypophysial substances, or storage of exogenous material.

Cryptocotyle lingua in British Mink

THE development of the intermediate stages of heterophyid trematodes of the genus *Cryptocotyle* commences in sea snails and continues in various species of coastal fish. The definitive hosts are birds and mammals which eat infected fish. These flukes have been recorded from various hosts in Britain. Thus Lewis[1] found *C. lingua* in the herring gull, *Larus argentatus*, and *C. concava* in the black-necked grebe, *Podiceps nigricollis*, both in the Aberystwyth area, while Mahfouz A. M. Fahmy, whose unpublished observation is quoted by Lapage[2], found *C. lingua* in an otter, *Lutra lutra*, in the suburbs of Edinburgh in 1953. *Cryptocotyle* spp., chiefly *C. lingua*, have been recorded in mink, *Lutreola vison*, by various authors on the continent of Europe[3] and in North America[4].

Since British farm mink are largely fed on raw sea-fish, a particular search was made during routine post-mortem examinations for alimentary parasites in general and fish-borne trematodes in particular.

Of 37 mink so far examined, one was found to have four specimens of *C. lingua* in the small intestine. Characteristic eggs were found in the rectal fæces.

Small numbers of eggs 50µ × 23µ and 30µ × 18µ were found in the intestinal contents of another mink. These were attributed to *C. lingua* and *C. concava* respectively; but no recognizable parasites were found in the intestine, possibly due to post-mortem disintegration. So far as can be ascertained, this is the first report of *C. lingua* in mink in Britain.

I am indebted to my colleague Mr. K. W. Head, of the Department of Pathology, for the opportunity to carry out these examinations.

Multiple-Mutation Theory of Carcinogenesis

NEW life was given to the somatic mutation theory of carcinogenesis when it was recognized that not just one, but several mutations were probably required. Fisher and Hollomon[1] thought that a number of similar mutations in adjacent cells might initiate cancer, and deduced a law of the form (age)$^{p-1}$ for the rate of appearance of cancers in a population, with p being the number of cells in the critical size group. They arrived at a value of p near 7 from the mortality data. Muller[2] and Nordling[3] thought that a number of successive mutations in the same cell might initiate cancer, and deduced a law of the same form, (age)$^{p-1}$, for the rate of appearance of cancers, with $p \approx 7$ now being the number of mutations required in a single cell.

Nordling[4] recognized that mutation would, in general, tend to render cells less able or more able to survive than their normal neighbours, and that for once-mutated cells to be preserved for subsequent mutations they must be more, rather than less, able to survive. Platt[5] made this point clearer by emphasizing that each somatic mutation that survives must lead to a clone of mutated cells growing at the expense of their normal neighbours. Armitage and Doll[6] recognized that the growth of the clone generated by the first mutation was important in increasing the number of cells in which the second could occur, and showed that the mortality data could fit fairly well with a two-mutation theory if an exponential rate of clone growth was assumed.

Based upon these multiple-mutation ideas, the most realistic theory now would seem to require the following sequence of events: (1) mutation; (2) clone growth from the mutated cell; (3) another mutation somewhere in the clone; (4) growth of a new clone from the cell with the second mutation; (5) a third mutation in the second clone and so on until a cancer clone is the result. The first three steps of the above sequence are essentially the two-stage theory of Armitage and Doll[6], if it is assumed that the growth-rate of the first clone is exponential. However, I believe there is a more reasonable growth-rate than the exponential, which leads to an improved agreement between theory and experience.

Free cells, such as bacteria, are observed to grow exponentially in number, as long as the conditions for growth are maintained. They do so because they divide again and again at a constant rate, each generation doubling the number of cells present. The cells in the germinal layer of adult mammalian epithelium, on the other hand, stay essentially constant in number in spite of a finite mitotic rate. After mitosis, half the daughter cells leave the germinal layer and move outward, maturing and finally dying. The maturing cells no longer divide, so that a constant number of reproducing cells is maintained in the germinal layer whatever the mitotic rate. Consider now a clone of mutated cells in epithelial tissue. If the clone be non-malignant, the advantage of the mutated cells over their normal neighbours is likely to be small, and the germinal layer of the clone should expand laterally at some slow rate. Since the environment at the perimeter of the clone is in an essentially steady state—a sheet of mutated cells in edgewise contact with a sheet of normal cells—the rate of spreading of the clone should remain approximately constant. (Only when the clone consists of half a dozen cells or fewer should the lateral growth-rate differ from its final constant value, for only then is the perimeter of the clone appreciably curved on the scale of cellular dimensions.) The mitotic rate in the interior of a clone should not affect its rate of spreading at all, for the reasons already discussed for normal epithelium.

If the radius of a clone increases at a steady rate, say $r = \alpha(t - \tau)$, where r is the clone radius, t is the time, τ is the time at which the clone started growing, and α is a constant, then the area of the clone will be $a = \pi r^2 = \pi\alpha^2(t - \tau)^2$. The number of cells in the clone will be proportional to its area, hence

$$\text{number of cells} = \beta(t - \tau)^2 \qquad (1)$$

where β is a constant, t is time, and τ is the time of clone initiation. A law of this sort for the growth of non-malignant mutant epithelial clones seems more reasonable than the exponential, which should correspond more nearly to malignancy.

The consequences of a power law of the form $\beta(t - \tau)^2$ for the number of cells in a clone are very interesting and suggestive. Assume first the simplest possibility, namely, that all mutation-rates and clone growth-rates are constant. Then the rate of appearance of cancers in a population should be proportional to a power of the time,

$$\text{Cancer-rate} \sim (\text{age})^{3(n-1)} \qquad (2)$$

where n is the number of mutations required. Consider $n = 1, 2, 3$ successively in detail. For $n = 1$, equation (2) indicates that the rate is a constant, as it should be if the first mutation were to produce cancer. Cancers of this type, appearing at an early age in many members of the population, would be strongly selected against genetically, and should largely have been eliminated through the evolutionary process. However, carcinogenic materials that were not often found in the environment of our ancestors might be able to produce single-mutation cancers.

For $n = 2$, the number of clones produced by the first mutation is proportional to (age) and the average number of cells in each to $(\text{age})^2$. The aggregate number of cells where the second mutation can occur is then proportional to $(\text{age})^3$. If the second mutation leads to cancer, the cancer initiation-rate will be proportional to $(\text{age})^3$ as the formula $(\text{age})^{3(n-1)}$ indicates. That this expression is correct can be seen by direct computation of the number of cells in the various clones at time t. Let R be the mutation-rate per individual, so that his number of mutant clones is Rt. Then in the time interval τ to $\tau + d\tau$ the number of clones formed is $R\,d\tau$. Each of them at subsequent time t contains $\beta(t - \tau)^2$ cells. Adding, the total number of cells is

$$n = \int_{\tau=0}^{t} \beta(t - \tau)^2 R\,d\tau = R\beta t^3/3$$

For $n = 3$, another factor of $(\text{age})^3$ is introduced, giving finally $(\text{age})^{3(n-1)} = (\text{age})^6$ for the rate of appearance of a three-mutation cancer.

The large number of human epithelial cancers with incidence-rates observed to be proportional to $(\text{age})^6$ suggests strongly that three mutations are required for the initiation of most human carcinoma.

Suppose now that the question of chemical or radiation carcinogenesis is raised. Again assume the simplest conditions: uniform exposure to a carcinogenic agent that produces all the required mutations, and uniform growth-rate of clones. Then the rate of appearance of cancer is proportional to a power of the dose-rate as well as to a power of the time,

$$\text{Cancer-rate} \sim (\text{dose-rate})^n(\text{age})^{3(n-1)} \qquad (3)$$

The dose-rate appears only to the power n because it affects only the n required mutations and not the $(n - 1)$ clone growth-rates. If the carcinogen were to cause only m of the mutations, with $m < n$, then the cancer initiation-rate would be

$$\text{Cancer-rate} \sim (\text{dose-rate})^m(\text{age})^{3(n-1)} \qquad (4)$$

and would be directly proportional to the concentration of carcinogen should $m = 1$.

When the dose of carcinogen varies with time, it is easy to see that many different time-dependences can be obtained for the rate of incidence of cancer. Similarly, if the growth-rates of clones were to depend upon the hormone balance of the organism and to change with time, as suggested by Armitage and Doll[6], still other time-dependences could be obtained.

Multiple-mutation theories of carcinogenesis will have to stand or fall through the degree of their agreement with observations of the progress of the disease in afflicted organisms, and with the increases in the cancer-rate produced by age, carcinogenic materials, and radiation. Semi-quantitatively, at least, the model here proposed appears to be in agreement with such observations.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, March 3

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE, PHILOSOPHY OF SCIENCE GROUP (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 4.30 p.m.—Annual General Meeting. 5.30 p.m.—Mr. F. Greenaway: "The Phlogiston Theory and Collingwood's Philosophy of History".

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. C. E. Tharratt: "The Saunders-Roe Pulse Jet Engine".

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. J. A. Wheeler (Princeton University): "Physics as Geometry—the Present Status of Einstein's Programme".* (Further lectures on March 5 and 10.)

UNIVERSITY OF LONDON (at the Westminster Hospital Medical School, Horseferry Road, London, S.W.1), at 5.30 p.m.—Dr. Otto Westphal (University of Freiburg): "Bacterial Endotoxins (Lipopolysaccharides)—Chemical and Immunological Aspects".*

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. T. R. Puzey: "The Application of Nuclear Energy to Power Production".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Battersea Grammar School, Abbotswood Road, Streatham, London, S.W.16), at 6.30 p.m.—Dr. H. J. Barber, Dr. I. L. Jones, Dr. J. H. Pryor, Dr. J. A. Read, Dr. C. W. Herd and Dr. K. G. A. Pankhurst: "Careers in Chemistry".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Sir Frederic Bartlett, F.R.S.: "Applications of Psychology".

AMBASSADE DE FRANCE, BUREAU SCIENTIFIQUE (at the French Institute, 15 Queensberry Place, London, S.W.7), at 8.30 p.m.—Monsieur l'Inspecteur Général G. Laclavère: "Contribution Française à l'Année Géophysique Internationale".

Tuesday, March 4

INSTITUTION OF CHEMICAL ENGINEERS (at the Hoare Memorial Hall, Church House, Westminster, London, S.W.1), at 9.30 a.m.—Spring Meeting.

AMBASSADE DE FRANCE, BUREAU SCIENTIFIQUE (in the Chemistry Theatre, Royal College of Science, London, S.W.7), at 1.30 p.m.—Monsieur l'Inspecteur Général G. Laclavère: "Oil in the Sahara".

INSTITUTION OF POST OFFICE ELECTRICAL ENGINEERS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5 p.m.—Mr. E. L. Bubb and Mr. K. R. Wilderspin: "The Use of Rectangular Loop Magnetic Material in Electronic Switching Circuits".

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. E. Bünning (University of Tübingen): "Endogenous Diurnal Periodicity in Plants and Animals".* (Further lectures on March 5 and 7.)

INSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION CIRCLE (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Some Impressions of Technical and Industrial Training in the United States", opened by Dr. K. R. Sturley.

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Mathematics in Mechanical Engineering".

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "The Future of the Railways". Chairman: Major-General G. N. Russell. Speakers: Monsieur l'Ingénieur Principal P. Weil and Mr. H. P. Barker.

UNIVERSITY COLLEGE OF NORTH STAFFORDSHIRE (in the College Conference Hall, Keele, Staffordshire), at 8.30 p.m.—Prof. M. Polanyi, F.R.S.: "Understanding Ourselves". (First of three Lindsay Memorial Lectures on "The Sciences of Man". Further lectures on March 6 and 10.)

Wednesday, March 5

ASLIB (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 10 a.m.—Conference on "Scientific and Technical Translation".

NATIONAL INSTITUTE OF OCEANOGRAPHY (at Wormley, Godalming, Surrey), at 2.30 p.m.—Dr. G. Laclavère: "The French Contribution to the International Geophysical Year".

PHYSICAL SOCIETY COLOUR GROUP (at the Institute of Ophthalmology. Judd Street, London, W.C.1), at 3.30 p.m.—Cdr. Dean Farnsworth (U.S. Naval Research): "How the World Looks to a Color Blind".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. D. A. Robson: "The Geological Structure of the Wadi el Dirba Area of Sinai"; Dr. Frances E. S. Alexander: "Observations on Tropical Weathering—a Study of the Movement of Iron, Aluminium and Silicon in Weathering Rocks at Singapore".

INSTITUTE OF PHYSICS, EDUCATION GROUP (at 47 Belgrave Square, London, S.W.1). at 5.15 p.m.—Annual General Meeting. 6 p.m.—Dr. Martin Johnson: "The Spinning Galaxy—a History in Co-operation between Sciences".

AMBASSADE DE FRANCE, BUREAU SCIENTIFIQUE (at the Institute of Transport, 80 Portland Place, London, W.1), at 5.30 p.m.—Monsieur l'Ingénieur Principal P. Weil: "The Latest Developments and Future Prospects of the S.N.C.F.".

UNIVERSITY OF LONDON (at the Westminster Hospital Medical School, Horseferry Road, London, S.W.1), at 5.30 p.m.—Dr. Otto Westphal (University of Freiburg): "Bacterial Endotoxins—Biological Activities and Investigations on their Mode of Action".*

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at 14 Belgrave Square. London, S.W.1), at 6.15 p.m.—Dr. D. Dickinson: "Relationship of Chemical Composition to Quality in Fruit and Vegetables for Canning"; Mr. L. P. Burroughs: "The Free Amino Acids of Certain Fruits".

Thursday, March 6

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. J. H. Callomon: "Electronic Emission Spectra of the Carbon Disulphide Ion, CS_2^+"; Mr. N. K. Bridge and Mr. G. Porter: "Primary Photoprocesses in Quinones and Dyes".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. F. Busemann and Mr. W. Casson: "Results of Full-Scale Stability Tests on the British 132 kV. Grid System"; Dr. F. H. Last, Mr. E. Mills and Mr. N. D. Norris: "The Organization for Large-Scale Grid System Tests".

INSTITUTE OF REFRIGERATION (at the Junior Institution of Engineers, Pepys House, 14 Rochester Row, Westminster, London, S.W.1), at 5.30 p.m.—Monsieur P. Vidal: "Modern Trends in Cold Store Design and Operation in France".

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "How Should Liberal Studies be dealt with in Technical Colleges?"

INSTITUTE OF METALS, LONDON LOCAL SECTION (at 17 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. B. E. Hopkins: "High Purity Iron".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. W. R. Hawthorne, F.R.S.: "Aero-Thermodynamics".

Thursday, March 6—Friday, March 7

NATIONAL ASSOCIATION FOR MENTAL HEALTH (at the Assembly Hall, Church House, Westminster, London, S.W.1), at 10 a.m. daily—Annual Conference—"The Report of the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency: Implications for Local Authorities and the General Public".

Friday, March 7

ASSOCIATION OF APPLIED BIOLOGISTS (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 10.50 a.m.—Symposium on "Frit Fly".

SOCIETY OF DYERS AND COLOURISTS, LONDON SECTION (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Dr. R. Wittwer: "Recent Developments in the Dyeing of Manmade Fibres".

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (in the Lecture Theatre of the Mining Institute, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. A. M. Laird, Prof. A. W. Scott and Prof. A. S. T. Thomson: "Experimental Investigations on Natural Circulation in Water-tube-boilers".

Saturday, March 8

BRITISH MYCOLOGICAL SOCIETY (in the Lecture Theatre, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 11 a.m.—Meeting on "Some Mechanisms of Variation in Fungi".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PHYSICIST, Senior grade (with an honours degree in physics, preferably in the field of radiotherapy), for duties in the Radiotherapy Department—The Personnel Officer, St. Thomas's Hospital, London, S.E.1 (March 8).

LECTURER (preferably with an interest in marine zoology) IN ZOOLOGY at the University College of Ghana—The Secretary Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 13).

PHYSICAL CHEMISTS (with an honours degree, or equivalent, and experience in corrosion or a related field) at the Research Laboratories, Leatherhead, Surrey, for work on corrosion problems arising in nuclear and conventional power stations—The Personnel Officer, Central Electricity Generating Board, 24/30 Holborn, London, W.C.1, quoting Ref. N/53 (March 14).

LECTURER in PHYSICS—The Secretary, St. Mary's Hospital Medical School (University of London), Paddington, London, W.2 (March 15).

RESEARCH ASSISTANT IN PHYSIOLOGICAL ELECTRONICS—The Secretary of University Court, The University, Glasgow (March 15).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY OR PHYSICS—The Secretary, The University, Exeter (March 24).

LECTURER or ASSISTANT LECTURER IN PLANT PHYSIOLOGY (with special reference to metabolism and plant biochemistry)—The Secretary and Registrar, The University, Southampton (March 24).

LECTURER or ASSISTANT LECTURER (preferably with qualifications in mathematical analysis) IN MATHEMATICS at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 28).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY, ENGINEERING and PHYSICS—The Secretary and Registrar, The University, Southampton (March 29).

Imperial Chemical Industries Research Fellows in Chemistry, Physiological Chemistry, Agricultural Chemistry, Agricultural Botany, Microbiology, Geology and Physics or related subjects—The Registrar (Room 22, O.R.B.), The University, Reading (March 31).

Lecturer (Engineer, Physicist or Applied Mathematician) in Civil or Mechanical Engineering—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 31).

Lecturer or Assistant Lecturer in Inorganic and Structural Chemistry—The Registrar, The University, Leeds 2 (March 31).

Lecturer (preferably with an interest in the mechanism of organic reactions) in Chemistry (Organic)—The Secretary, The University, Aberdeen (March 31).

Research Fellow (Zoologist, with interests in marine biology)—The Registrar, University College, Singleton Park, Swansea (March 31).

Reader in Soil Science—The Secretary, The University, Aberdeen (April 7).

Research Fellow in Natural Sciences or Engineering—The Secretary, Fellowships Committee, Trinity Hall, Cambridge (April 12).

University Students and Fellows, for experimental or theoretical research in nuclear and elementary particle physics—The Professor of Natural Philosophy, The University, Glasgow (April 12).

Chair of Geography—The Registrar, The University, Birmingham 15 (April 18).

Esso Student in Chemical Engineering—The Registrar, Imperial College, London, S.W.7 (April 25).

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology and Physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Lecturer (with an honours degree in mathematics and experience in numerical methods and programming high-speed digital computers) in Computing in the Department of Mathematics—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks (April 30).

Senior Lecturer in Bacteriology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, April 30).

Turner and Newall Research Fellow in Engineering, Inorganic Chemistry or Physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Lecturer in Fuel Technology and Chemical Engineering—The Registrar, The University, Sheffield (May 1).

Esso Student in Chemical Engineering—The Registrar, University College, Gower Street, London, W.C.1 (May 16).

Assistant Professor in the Department of Physics—University of New Brunswick, Fredericton, N.B., Canada.

Director (preferably physicist, with experience of research in fibre technology at a textile research institute in the U.K.) of Jute Research (Technology) at the Jute Research Institute, near Dacca, East Pakistan—The Ministry of Labour and National Service (E.9), Almack House, King Street, London, S.W.1, quoting A.12/PAK/163/TCS.

Lecturer or Assistant Professor in Chemistry—Department of Chemistry, United College, Winnipeg, Manitoba, Canada.

Mathematicians and Physicists (honours graduates in mathematics or physics) at the A.E.R.E. Harwell and the A.E.E. Winfrith (Dorset), for work in theoretical reactor physics, neutron transport theory and numerical analysis—Group Recruitment Officer (1029Y/34), Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Metallurgist (British of British parents, an honours degree in metallurgy or A.I.Met. or equivalent, and industrial experience in ferrous and non-ferrous metallurgy) at the Ministry of Supply Royal Ordnance Factory, Birtley, for research and development work in connexion with new ammunition manufacturing processes involving hot- and cold-drawing and extrusion of ferrous and non-ferrous materials—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F.138/8A (March 21).

Professor/Assistant Professor in Physical Chemistry; a Professor/Assistant Professor in Inorganic and General Chemistry; and an Assistant Professor/Lecturer in Biochemistry—The Dean, College of Arts and Sciences, The University, Baghdad, Iraq.

Senior Lecturer in Animal Husbandry, Lecturer in Agriculture (Pedology and Soil Science), Lecturer in Agriculture (Animal Nutrition), Lecturer in Agricultural Chemistry, and a Lecturer in Animal Husbandry at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Senior Technician (preferably with experience of histology and other biological techniques) in the Anatomy Department, for research and classwork—The Secretary, University College, Gower Street, London, W.C.1, quoting 'Anatomy/7'.

Technician (preferably with some experience in electronics) in the Nuclear Engineering Laboratory, to assist in work on an electronic reactor simulator and other similar projects—The Registrar (NPT), Queen Mary College (University of London), Mile End Road, London, E.1.

ION EXCHANGE RESINS FOR CHROMATOGRAPHY

A complete range of "Zeo-Karb 225" and "De-Acidite FF" ion exchange resins for chromatographic separations and other analytical purposes is now being produced by The Permutit Company Ltd. A new production unit has been established especially for this purpose. Details of the resins are shown in the table on the right.

The crosslinking of "Zeo-Karb 225" cation exchange resins is given in terms of nominal weight percentage of divinylbenzene in the hydrocarbon polymer. The corresponding weight swelling or water regain is also given.

Only the weight swelling, or water regain is specified for the "De-Acidite FF" because extra crosslinks, in addition to those originally placed in the hydrocarbon structure, are introduced during manufacture. It is thus not possible to produce "De-Acidite FF" in as wide a range as "Zeo-Karb 225" because materials with very high water regain are difficult to manufacture reproducibly.

"ZEO-KARB 225"

Griffin AUTOPOISE CENTRIFUGE

A unique model with a self-balancing head and a rotating bowl

The "Autopoise" Centrifuge is of a novel type in which the rotating system includes the bowl as well as the centrifuge head. The motor frame is mounted on three resilient supports which allow limited lateral freedom of movement to the rotating system.

The centrifuge is quiet in operation; has a low power consumption due to diminished windage; is self-balancing and requires no special care in equipoising tubes; needs little maintenance since the self-balancing principle imposes diminished side thrust on the motor bearings; minimises the heating effect of rotation since the bowl rotates with the head; gives sharp sedimentation of materials as notoriously difficult to separate as freshly-precipitated calcium oxalate.

A light metal bowl approximately 14 in. diameter is clamped to and encloses the 8-place head, with which it revolves. A light metal lid closes the bowl and is secured by a knurled nut, threaded to accommodate a liquid vortex speed indicator. A speed-regulating rheostat, an on-off switch, a braking switch and a pilot light are incorporated in the base, which is mounted on rubber feet. Supplied with 6 ft. T.R.S. cable.

S17–720 (without buckets or tubes) ... £49 10s. 0d.

May we send you further information ?

LECTURES AND COURSES

QUEEN MARY COLLEGE
(UNIVERSITY OF LONDON)

POSTGRADUATE DIPLOMA IN NUCLEAR ENGINEERING

A one year course of study in Applied Nucleonics and Reactor Theory will be given during the Academic Year 1958-9, and will prepare students for the above diploma. A good honours degree in engineering, science, or mathematics is a necessary entry requirement. Studentships will be available to suitably qualified applicants but immediate application is necessary.

A brochure describing the course can be obtained from the Secretary, Nuclear Engineering Laboratory, Queen Mary College, Mile End Road, London, E.1.

BIRKBECK COLLEGE
(UNIVERSITY OF LONDON)

Session 1958/59 begins Monday, September 29, 1958

Part-time (evening) courses provided for Internal degrees in the Faculties of Arts and Science. Facilities also provided for full-time and part-time students reading for

- (i) Higher Degrees by thesis in Arts and Science.
- (ii) M.A. and M.Sc., Mathematics and M.Sc., Crystallography by examination.
- (iii) Academic Postgraduate Diplomas in Psychology and Numerical Analysis.

The College also invites applications from full-time and part-time students wishing to take by thesis higher degrees in statistics.

The Department of Scientific and Industrial Research has accepted the Postgraduate Diploma Courses in Psychology and Numerical Analysis, and the M.Sc. Crystallography course, as suitable for tenure of its Advanced Course Studentships. Students intending to read for Higher Degrees in Science by thesis are invited to inquire of the College whether it has available any D.S.I.R. Research Studentships.

Applications for admission to the College should be made before June 1. Pamphlet and form of application may be obtained from the Registrar, Birkbeck College, Malet Street, W.C.1.

UNIVERSITY OF LONDON: A COURSE of two lectures entitled "The Inside of the Earth" will be delivered by Sir Edward Bullard (Cambridge) at 6 p.m. on March 7 and 14 at Bedford College, Regent's Park, N.W.1. Admission free, without ticket.—James Henderson, Academic Registrar.

OFFICIAL APPOINTMENTS

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for either an Assistant Lectureship or a Lectureship in the Department of Geology. Candidates should have special interests in sedimentation. Salaries: Assistant Lectureship, not less than £700 per annum. Lectureship, £900 by £50 to £1,350 by £75 to £1,650 per annum. Commencing salary in each case will be at a point on the appropriate scale according to age, qualifications and experience. Membership of the F.S.S.U. and children's allowance scheme.

Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, to whom applications (six copies) must be sent by March 15, 1958.

UNIVERSITY OF OTTAWA
POST-DOCTORAL FELLOWSHIP IN CHEMISTRY

Applications are invited for a post-doctoral Fellowship tenable at the University of Ottawa in October, 1958, for work on thermodynamic and relaxation behaviour of polyblycol-solvent systems. The fellowship will carry a remuneration of $4,500 and will extend for at least two years, being renewable annually.

Applications, stating the names of two referees, should be sent to Dr. B. E. Conway, Department of Chemistry, University of Ottawa, Ottawa, Canada by March 31, 1958.

UNIVERSITY OF BAGHDAD
IRAQ

Applications are invited for the following three appointments in the Department of Chemistry, College of Arts and Science, Baghdad:

1. Professor/Assistant Professor in PHYSICAL CHEMISTRY.
2. Professor/Assistant Professor in INORGANIC and GENERAL CHEMISTRY.
3. Assistant Professor/Lecturer in BIOCHEMISTRY.

Candidates for the first two posts must hold a doctorate in chemistry and possess sufficient experience in teaching the subject concerned at the B.Sc. honours level. Evidence of a good academic record and of a sustained interest in original research is essential. Experience in preparing students for postgraduate degrees will be considered as an additional qualification.

Candidates for the post of Assistant Professor/Lecturer in BIOCHEMISTRY, must possess a good academic record with training in biochemistry at least up to the B.Sc. honours standard. A Ph.D. degree (or equivalent) in biochemistry or chemistry, with evidence of continued interest in original research, is essential. Experience in teaching biochemistry at the undergraduate level will be considered as an additional qualification.

Salary range (I.D.1 = £1):

Professor, I.D.2,400 to I.D.3,000 per year.
Assistant Professor, I.D.1,800 to I.D.2,400 per year.
Lecturer, I.D.1,560 to I.D.1,920 per year..

Cost of living allowance of at least I.D.144 per year. The contract could be for one or three years.

Free passages for himself, wife and two children under 13 years, at the beginning and the end of contract. Medical care and leave according to rules. Annual summer vacation entitlement. Teaching is done in English.

Applications for each of the three posts should include particulars about age, nationality, marital status, academic record, teaching and research experience and present position. A list of publications, copies of testimonials and a recent photograph should also be submitted.

Further inquiries and correspondence should be addressed to the undersigned.

A. A. DURI,
Dean, College of Arts and Science.

UNIVERSITY OF WESTERN ONTARIO
DEPARTMENT OF PHYSICS
RESEARCH ASSOCIATESHIPS IN EXPERIMENTAL AND THEORETICAL PHYSICS

Applications are invited for postdoctoral and predoctoral Research Associateships in experimental and theoretical chemical physics tenable in The Molecular Excitation Group from August 1958. The research interests of the group cover a wide range of excitation problems related to combustion, radiation chemistry, astrophysics, and atmospheric physics.

Further information may be obtained by writing by air mail to Dr. R. W. Nicholls, Department of Physics, University of Western Ontario, London, Ontario, Canada.

UNIVERSITY OF GLASGOW
UNIVERSITY STUDENTSHIPS AND FELLOWSHIPS

Applications are invited for University Studentships and Fellowships for experimental or theoretical research in Nuclear and Elementary Particle Physics. Salary scale: Studentships, £350 to £500 per annum, according to qualifications, with a tenure of three years. Fellowships, £600 to £900 per annum, according to qualifications. Tenure three years on appointment, with possible renewal for further period of two years. These Fellowships will be superannuated under the F.S.S.U.

Applications, stating age, academic qualifications, research experience and names of two referees, should be sent to the Professor of Natural Philosophy, the University, Glasgow, W.2, before April 12, 1958.

UNIVERSITY COLLEGE OF SWANSEA
DEPARTMENT OF ZOOLOGY

Applications are invited from zoologists with interests in marine biology for a Research Fellowship tenable for three years. The salary may be up to £800 per annum.

Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, to whom applications (three copies), should be sent by March 31, 1958.

UNIVERSITY OF BRITISH COLUMBIA
DEPARTMENT OF PHYSICS

Applications are invited for appointments as Lecturer, Assistant Professor, Postdoctorate Fellow and Research Assistant in the Department of Physics. The vacancies have been created by the rapid expansion of the university. They are mainly in the fields of nuclear physics, optical spectroscopy, solid state physics and geophysics. Applicants should have an honours degree in physics and, except in the case of Research Assistants, a Ph.D. degree. They should not be more than 30 years of age and should be available in September, 1958. There are also Teaching Assistantships available to help students who wish to pursue graduate work towards a Ph.D. degree.

Applicants wishing fuller information regarding any of these positions or awards should write to G. M. Shrum, Head, Department of Physics, University of British Columbia, Vancouver, B.C., Canada.

MEMORIAL UNIVERSITY OF NEWFOUNDLAND
ST. JOHN'S, NEWFOUNDLAND, CANADA

Applications are invited for the following positions on the academic staff of the University, to take effect from September 1, 1958. All appointments are made originally for a two-year provisional period, establishment on a permanent basis being subject to confirmation. The appointees will be required to deal principally with undergraduate courses, pass and honours, but participation in the master's course may be required in some cases. Assistant Professor in the Department of Chemistry, to teach Physical Chemistry. Assistant Professor in the Department of Mathematics. Assistant Professor in the Department of Physics. Assistant Professor in the Department of Biology, to teach Invertebrate Zoology. The annual salary scale is $4,400 to $6,000, on annual increments. Depending on qualifications, etc., appointments may be made above the minimum figure. Scales carry efficiency bars at certain points. There is provision for contribution towards transportation expenses, and a liberal contributory Pension Plan exists.

Applications, with complete curriculum vitae, and the names and addresses of three referees, should be addressed to The President, Memorial University of Newfoundland, St. John's Newfoundland, Canada, by April 8, 1958. In addition, two copies should be sent to the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, to reach him by the same date.

GOVERNMENT OF NORTHERN IRELAND

Applications are invited for pensionable post of Senior Scientific Officer in Dairy Bacteriology Division, Ministry of Agriculture. Candidates must be British subjects normally resident in the United Kingdom, and possess an honours degree in bacteriology, biology or agricultural science and since graduation have specialized in bacteriology. Candidate should have had experience which would fit him to undertake investigations concerning bacteriology of eggs and allied fields of food and agricultural bacteriology. Salary scale, £1,160 to £1,370. A candidate with special qualifications and experience may be offered a salary above the minimum. The candidate appointed may be required to undertake certain teaching duties in Department of Agricultural Bacteriology of Queen's University of Belfast. Preference will be given to ex-Servicemen.

Application forms obtainable from Secretary, Civil Service Commission, Stormont, Belfast, should be returned, together with copies of two recent testimonials, by March 19, 1958.

UNIVERSITY COLLEGE OF GHANA

Applications are invited for (A) Assistant Lectureship or (B) Lectureship in Physics. Interest in geophysics an advantage. Salary scales: (A) £900 per annum; (B) £1,000 by £50 to £1,350 b £75 to £1,800; £1,850 per annum. Entry poin according to qualifications and experience F.S.S.U. Outfit and family allowances. Passage for appointee and family on appointment, annua leave and normal termination. Part-furnished ac commodation at a charge not exceeding 7.5 pe cent of salary.

Detailed applications (six copies), naming thre referees, by March 13, 1958, to Secretary, Inte University Council for Higher Education Oversea 29 Woburn Square, London, W.C.1, from who further particulars may be obtained.

NOW PROVES THE REMARKABLE POTENTIALITIES OF VACUUM BRAZING

One of the logical developments of VACUUM METALLURGY, which can be fully investigated with the EDWARDS SMALL-PRODUCTION VACUUM FURNACE, is VACUUM BRAZING.

This exciting new development overcomes the major difficulties of oxide deposits, ensures perfect "wetting" by the brazing material without the need for flux, so yielding greater strengths and making brazing possible where previously it was not practicable.

For better vacuum service . . .

CASELLA LONDON

A NEW INSTRUMENT FOR SAMPLING AIRBORNE DUST–

THE HEXHLET

This instrument enables a bulk sample of the 'respirable' fraction of a dust cloud to be collected for subsequent chemical analysis. It employs a horizontal elutriator consisting of a number of flat horizontal ducts through which air is drawn at a constant velocity, such that particles above about 7μ will settle out before reaching the end. The air flow is maintained constant by means of a 'critical orifice'. Suction is provided by an air ejector. The respirable fraction of the dust is collected in a Soxhlet filter thimble which will hold up to 2 grammes of dust before its resistance becomes too high.

CO-OPERATION IN RESEARCH AND DEVELOPMENT

THE impracticability of national self-sufficiency in defence had been increasingly recognized in Anglo-American relations, even before the Declaration of last autumn gave full expression to the common agreement that Britain and the United States can no longer afford to waste resources in skill and money but must make joint efforts fully co-operative. That much was recognized by the Howitt Committee, reporting in 1956, as a decisive reason for its reluctant recommendation that the Government should have permanent but limited powers to acquire the use of technical information in contracts for the supply of material for defence purposes. The resources of materials and of man-power in Britain are quite inadequate for us to hope to carry out in Government departments all the research that is desirable for defence purposes, and the real question behind the discussion on the Defence Contracts Bill is how far it will promote or hinder the free circulation of technical and scientific information.

That is only one aspect of defence research, on which some 10 per cent of the defence vote is spent. An even more vital one for Britain is raised in the Fifth Special Report from the Select Committee on Estimates for the Session 1956–57*. The greater part of this document consists of the observations of the Admiralty upon the seventh report of the Select Committee on Estimates for the session 1955–56 on naval research and development ; but it also contains some comments from the Minister of Supply and the Minister of Defence on other recommendations of the Committee, in its second report of the session 1955–56, which are no less pertinent to the whole question of the scale and organization of defence research.

In its seventh report for the session 1955–56, the Committee recommended an immediate examination of the possibility of merging naval and research development establishments with those working for other Government departments, including the Council for Scientific and Industrial Research, wherever this merger is practicable. The final decision on which establishments are to be merged should rest, the Committee suggests, with the Ministry of Defence. The Admiralty has during the past ten years or more been under fairly strong criticism for its reluctance to co-operate fully in research, and it now explains that it is already planning the merger of several of its own research and development establishments. A large measure of integration of the Services' research and development programmes, and of co-ordination between those activities and those of non-Service research and development establishments already exists, and in particular, where appropriate, one Department assumes responsibility for the conduct of all research in certain fields.

The present report of the Select Committee announces that in the light of the Committee's earlier recommendation and of changes in the defence programme, the Ministry of Defence has agreed to undertake a review of all research and development facilities. This may prove to be a step forward, though it may carry us no further than the review of expenditure on research and development generally, which was made ten years ago by the Select Committee on Estimates. What is needed is a review not of research facilities and plants but of defence research as a whole, and its balance with the national research effort as a whole. Only, for example, in such a context is it possible to judge how far our effort in nuclear research is adequate and justifiable in relation to the rest of the research effort demanded of the strictly limited resources—in man-power, institutions and materials—that are available in Britain ; and whether it is reasonable to employ some 20,000 qualified scientists and engineers in the Government services.

In this connexion, it is important to remember that, as Sir John Cockcroft recently remarked in Amsterdam, research equipment is now becoming so expensive that some must be considered not national but even international ventures if national economy is not to be distorted and a really efficient return secured on the investment. Under such conditions, it may become essential to consider the abandonment of whole projects, possibly in agreement with other countries. The fatal way could well be that beloved of the politician, of paring 10 per cent here and there in the hope of achieving a useful economy in the aggregate.

Before considering the further implications of this proposal to review defence research and development facilities, it is as well to note the comments on other recommendations of the Select Committee. The Admiralty has agreed to amend the heading in the Navy Estimates, "Research work by other Government Departments on Admiralty behalf", to read, in the 1957–58 Estimates, "Stores and equipment supplied to, and research done for, Admiralty research departments by other Government departments, etc.", and a note is to be added to make it clear that the Subhead 0 does not include all naval expenditure on research and development. The recommendation that for proposals for new works, services and equipment, research and development establishments should be treated as a single headquarters service, and also the recommendations for extending to research and development the policy of amalgamating establishments with powers to make their proposals direct to the Admiralty, has been accepted ; but the Admiralty does not regard it as desirable or practicable to allow each of thirty research establishments a separate fund with discretion to spend up to £300 on individual items, though it has been decided to set aside each year a small central reserve fund to be administered by the Director of Research Programmes and Planning on which superintendents of research establishments can indent.

---

* Fifth Special Report from the Select Committee on Estimates, Session 1956–57. Pp. 25. (House of Commons Paper No. 307.) (London: H.M. Stationery Office, 1957.) 1s. 3d. net.

The Admiralty questions whether the recommendation that research and development establishments should be made responsible to a single organization in the Admiralty for purposes of their programme of research, staffing and progress gives sufficient weight to the position of the Deputy Controller (Research and Development), who as scientific adviser to the Board of Admiralty and as deputy to the Controller is responsible for supervizing and co-ordinating the research and development programmes. Accordingly, the Admiralty suggests that no great advantage is likely to result from placing such establishments under the direction of the heads of the purely scientific departments in the same way as the basic research establishments already do. It is pointed out that the Committee's proposals would separate the responsibility for research and development from that for the final design and production, and that the Admiralty would prefer to reserve final judgment pending the report of the Admiralty Committee, under the chairmanship of Sir Barclay Nihill, which is at present reviewing Admiralty organization in the material field.

In the discussion of this recommendation, there is no reference to the Defence Research Policy Committee or the position of the Deputy Controller in relation to that Committee, of which he is a member. This omission also bears on two other recommendations which the Admiralty has, in principle, accepted: that if it is decided in future to open a new research and development establishment, particular care should be taken to site it in an area where it will not recruit in competition with existing research and development establishments, and that an early choice should be made between finding more suitable premises for the Royal Naval Physiological Laboratory and arranging for such work as is necessary to be done elsewhere. Indeed, it already appears that if the most effective use is to be made of existing research institutions and available scientific and technical man-power, a good deal of close co-operation between the Defence Research Policy Committee and the Advisory Council for Scientific Policy is necessary.

Three other recommendations of the Select Committee are rejected by the Admiralty. The Admiralty considers that the present system affords full opportunities for advancement consistent with the maintenance of proper standards, and accordingly does not propose to evolve a system of promotion from the 'assistant (scientific)' grade to the 'experimental officer' grade and from the latter to the 'scientific officer' grade, which already draws 8 per cent of its officers from the experimental officer grade while the latter draws 17 per cent from the scientific assistants. The Admiralty also maintains that its present procedure does obtain the most favourable possible research and development contracts with industry, nor does it accept the recommendation that the views of the Director of Navy Contracts should be sought at an earlier stage in the formulation of the research and development programme. His essential contribution is to ensure that the work is carried out with maximum value to the Admiralty; to consult him in the planning stage and in the decision which projects should be put out to industry and which should be carried out by the Admiralty research and development establishments, it is suggested, would not in general be of assistance.

The Select Committee on Estimates in its second report, 1955–56, recommended review of the system of control to ensure that research projects (on military aircraft) are not continued after they have outlived their usefulness. The Minister of Supply and Minister of Defence now claim that the Director-General of Scientific Research (Air) and the Finance Branch keep all research projects under continuous review, while the Research and Development Board of the Ministry of Supply considers the list of projects periodically, and the Aircraft Research and Development Programmes Committee, of which the Controller of Aircraft is chairman and which includes representatives of the Naval and Air Staffs, does so annually. These arrangements, it is believed, should ensure that no project is continued after it ceases to be worth while, and it is pointed out that while the primary purpose of a research aircraft is usually to explore new fields of aerodynamics, when this has been done, the use of such aircraft for the flight testing of engines and equipment required for later operational aircraft of comparable characteristics usually offers economy in both time and money.

A review of the effectiveness of the control by the Minister of Defence of projects was also recommended by the Committee. This control of the research and development programme is exercised in the main through the Defence Research Policy Committee, which has a strong scientific element in its composition, including the Secretary of the Department of Scientific and Industrial Research. The Committee is served by a small full-time scientific and military staff which conducts a preparatory examination of all projects, dealing with minor projects on behalf of the Committee. Moreover, the Committee does not confine itself to military considerations, but also takes account of the call that a given project would make on resources of money, man-power and capacity in relation to the military and scientific advantage that the project would secure.

To some extent the Defence Research Policy Committee does contribute to that informal and flexible exchange of views which Sir Owen Wansbrough-Jones described in his William Jackson Pope Memorial Lecture five years ago as an invaluable characteristic of the place which Britain now gives the scientist in the Services. Nevertheless, the circulation which the Defence Research Policy Committee's reports receive is inevitably restricted, and it would seem desirable to seek some further means of bringing outside informed criticism to bear on problems in which so large a scientific and technological element now enters, quite apart from the appraisal of the total defence research effort in relation to other demands on scientific and technical resources. The problem is essentially one of striking a balance between the free flow of information and the minimum amount of secrecy which defence considerations rightly demand; and it is important that due regard should be paid not simply to the dangers which may attend the disclosure of information, but also to the price which has inevitably to be paid in waste of man-power and materials and in the loss of constructive criticism and creative ideas for any secrecy or impediment to the flow of information in the proper professional channels.

Neither risk is to be lightly disregarded; at the present time, if Anglo-American co-operation in research and development is not to be hindered, the former must be a calculated risk. The right approach to both problems, however, is from the angle of securing the conditions in which scientific and technological work is most fruitfully pursued, of which the maximum freedom of interchange of information is one of the first. That is a factor also if any searching review is to be made of defence research as a whole, and of its balance with the national research effort generally. Much depends here on the formal and informal organization of that effort at the highest level, and on the relations between the Ministers of Defence and Supply and the Lord President of the Council, for example. If they are adequately served and advised, it does not appear inherently impossible that the existing structure should provide what is needed, though in recent years doubts have been freely expressed as to the adequacy of the Lord President of the Council's office in surveying civil research. Nor can the whole problem be divorced from that of the supply of trained man-power and the measures now being taken to maintain and increase that supply.

The effective disposition of scientific and technological man-power between defence and the several civil and industrial spheres, and the provision of adequate facilities, are really one problem. There must be no waste of trained man-power, either on work that could be carried out by less highly trained staff, through the absence of adequate equipment and facilities, by duplication of work being carried out elsewhere, or by failure to provide sufficiently for the communication of knowledge on which the stimulation of creative ideas largely depends. The task of co-ordination and balance is too immense to be entrusted to any one individual. It can best be carried out by ensuring that at all levels, from Ministers downwards, those concerned are fully alive to all the issues involved and capable of appreciating for themselves the scientific and technical aspects with the financial and military and other factors.

Nor is this simply a matter of Government organization alone. As was shown in the discussion which followed addresses to the Parliamentary and Scientific Committee on November 26, 1957, on problems of aircraft research and development in Great Britain, demonstration of an adequate policy to exploit our strength in aeronautical research—and in other fields—depends on the closest collaboration with industry. Without such co-operation and full understanding, we cannot hope to use to the full the powerful resources for research and development which exist in Britain, resources which in quality are often as good as exist anywhere. Moreover, as Sir William Farren pointed out, apart from the question of shortage of trained man-power, it is a matter of retaining the ablest young scientists and technologists at their most creative period. No increase in the total output of scientists and technologists is likely to add appreciably to those of the highest ability; and to provide the conditions which attract and retain the services of men of that class is a major responsibility not only of the aircraft industry but also of other industries, including the nationalized industries and public corporations.

The aircraft industry is not a typical example of relations between industry and the Government, especially the Services, though differences in relations are rather in degree than in kind. Two points at least which emerged in this discussion have wide validity: the selection of projects and the problem of continuity. They are indeed related and have a vital bearing on the problem of Anglo-American co-operation.

Referring to the assertion that research is too closely related to projects, Sir William Farren remarked that when well led, research will generate its own projects, and he emphasized the dependence of all technological advance on fundamental research and new knowledge. Once again the vital importance of the unimpeded dissemination of new knowledge is apparent, and it would be fatal if any arrangements with the United States were allowed to place unjustifiable restrictions on the circulation of such ideas. Apart from the disastrous results of such measures on the stimulation of new ideas, every effort should be made to bring home both here and, as tactfully as possible to our allies, the force of Sir Ralph Glyn's remark: "There has been more extravagance in expenditure due to documents being labelled 'Secret' than from any other single cause. . . . The word secret is very often applied in order to cover up extravagance".

In considering these relations between Government departments and industrial establishments in the matter of research, due weight should be given to factors which Sir George Thomson stressed in his Fawley Foundation Lecture, "The Strategy of Research", last autumn. His reasons for believing that the serious difficulties of Government research establishments outweigh their advantages bear closely on the question of the distribution of our research effort both in defence and in the civil field. Further, its distribution has implications in regard to the second point, that of continuity, which is particularly liable to be jettisoned in Government establishments.

The most important factor making for economy in research is the wise choice of targets or projects, and while it is true that one of the most difficult decisions which a director of research has to take is when to abandon a programme, it should be stressed that

that is not primarily or mainly a financial decision. Once a project has been selected, it should be carried through to completion, unless scientific and technical factors emerging in the course of the project point to its abandonment; it should not be liable to interruption to secure small 5 or 10 per cent savings in a research budget. On no other basis is the planning of research and development possible, and the need of the aircraft industry for this kind of security was emphasized before the Parliamentary and Scientific Committee.

This commitment in advance to expenditure bears closely on the practicability of achieving effective economy in co-operative research between Great Britain and the United States. It implies that each country must surrender its right to abandon support of a joint research or development project on which it has once agreed without the consent of the other parties to the agreement. Without this, waste rather than economy may result from such co-operative ventures. This implication is not likely to be accepted readily by the British Government, and it is essential that its importance and the reasons for such continuity should be clearly understood in advance. To that end scientists and technologists generally should ensure that their professional associations consider carefully and fully all that is involved in this question of the most effective deployment of resources in research and development, both in defence and in the civil field, and in the co-operation with the United States now being examined. Even more than critical examination of points of detail is the clear and creative thinking out of which sound constructive proposals will emerge.

PHYSICS AND METAPHYSICS

Causality and Chance in Modern Physics

By Prof. David Bohm. Pp. xi+170. (London: Routledge and Kegan Paul, Ltd., 1957.) 21*s*. net.

THIS is the most paradoxical book I have seen for many years. Its author is not only a distinguished physicist but also a thinker with progressive views on most things; yet he is blind to one of the greatest of the advances in rational thinking which the development of physics has initiated. He purports to discuss fundamental aspects of modern science, but, scorning the scientific method established since Newton's time, he revives the metaphysical attitude of system-makers like Descartes, whose self-assurance he wonderfully imitates. He holds out the expectation that his ideas will eventually elucidate the strange properties of matter in its states of highest energy, but there is not a word in the book about the possible relation of these properties to the themes treated at great length in it. The elementary style of exposition could easily mislead the unwary student into the belief that he is here presented with a straightforward account of the problem stated in the title; but what the specialist sees in these dreary pages is a picture distorted beyond recognition by misinterpretation and misrepresentation.

The author's original endeavour was to vindicate the traditional conception of deterministic causality in atomic physics. Having notoriously failed in this, he now tries to argue that one ought to consider more general types of causality, partaking of both determinism and chance: the element of chance appearing at any 'level' of description would have to be underpinned by the determinism of some hidden processes going on at a 'deeper' level. This novel conception, however, is not 'synthetic', as he thinks, but just confused; at any rate, it does not correspond to the actual situation with which we are confronted in atomic physics. In fact, the infinite sequence of deeper and deeper levels of reality, which Prof. Bohm imagines, appears to serve no other purpose than to provide him with a perpetual line of escape from embarrassing difficulties.

The true character of the causal relations of atomic physics was fully elucidated by Bohr and Heisenberg thirty years ago, and all that we have learned since about atoms and nuclei and other fundamental agencies of Nature has only strengthened the conclusions then reached and extended their scope. In particular, one of the most firmly established facts about the newly discovered mesons and hyperons is that the laws of their behaviour and interactions, whatever surprises they may hold in store for us in other respects, follow the general pattern of quantum theory, with its essentially statistical character. Thus, the great discovery of the non-conservation of parity in weak interactions refers to a typically non-classical feature, which can only be defined in statistical terms.

Altogether, it is impossible to discern in this new domain of experience the slightest foundation for the surmise that a return to some deterministic mode of description could throw light upon the phenomena. If some physicists nevertheless entertain such expectations, it is because, in contradiction with the exigencies of sound scientific method, they give to some metaphysical prejudice, like determinism, greater weight than to the immediate lessons of experience. That such irrational dogmatists should hurl the very accusation of irrationality and dogmatism at the defenders of the common sense, uncommitted attitude of other scientists is the crowning paradox which gives a touch of comedy to a controversy so distressingly pointless and untimely.

L. Rosenfeld

GEOLOGICAL INTERPRETATION OF MARINE SEDIMENTS

Géologie Sédimentaire

Les Séries Marines. Par Prof. Augustin Lombard. Pp. 725+13 planches. (Paris: Masson et Cie.; Liège: H. Vaillant-Carmanne, S.A., 1956.) 11,000 French francs.

PROF. A. LOMBARD of Brussels, previously a lecturer at Geneva, starts with a somewhat muddled warning against unreserved acceptance of the doctrine of uniformitarianism—a dreadful word replaced in French by actualism—which, for our purpose, may be interpreted as present-day-ism. Lombard quotes, with approval, a recent remark by Debyser that the present is only the key to the past, not its replica; but this of course is exactly what Hutton, Playfair and Lyell tried to teach us from the beginning.

Lombard's criticism of actualism is clearly based on confusion, since, by way of illustration, he blames the principle for six "hypothetical and mistaken interpretations", in regard to all of which it is perfectly innocent. For example, he complains that ripple-marks have long been thought to be restricted to shallow-water formations, whereas they have recently been photographed on the sea bottom at a depth of 2,000 m. The obvious answer is that the mistake was made through ignorance, not knowledge, of the present.

Lombard's main quarrel with the idea of interpreting the past in the light of the present is due to his fear that an observer of the present may be distracted by some short-term process; and so he may fail to realize an accompanying long-term process, which, though it produces no appreciable result within his experience, may be of great importance in the course of geological time. The typical example of this, in his opinion, is afforded by some geologists having attributed the graded bedding of many deep-sea sandstones to turbidity currents. He himself thinks that in most cases it is due to sea-bottom creep, analogous to solifluxion (soil-flow) commonly found on land. A graded bed, it may be explained, is one in which a relatively coarse base grades upwards into a relatively fine top. The connexion between turbidity currents and graded bedding seems to have been first advanced by myself in 1938; but its experimental confirmation and much more besides we owe to Kuenen. It is very doubtful whether many geologists will follow Lombard in the modification he has proposed.

While not agreeing with Lombard on quite a number of points I have found his book, especially Part I, pp. 11–208, full of stimulating discussion of such phenomena as island arcs, the mid-Atlantic ridge, continental shelves and slopes, atolls, submarine canyons, guyots (submerged truncated peaks), rhythmic sequences, etc. He gives brief, readable summaries of the views of many fellow-workers; and these are supported by a bibliography with 1,200 entries (50 per cent in French, 30 English, 20 German), along with a good index and contents. The whole should help future research quite considerably.

Like others in the same inquiry, Lombard finds it very useful to draw graphic sections of successions which he is investigating, whether in the field or in boreholes. Of late, such sections, where based on boring, have often been supplemented by curves recording electric resistance, radioactivity, etc. These latter-day curves supply additional information that cannot be derived from the graphic sections, although comparison, once all have been drawn, allows of valuable correlation. Now Lombard suggests supplementing each graphic section by a curve directly based upon it, using a succession of co-ordinates corresponding with sandstone, shale, limestone (and as many intermediate terms as may seem desirable). I confess I have found these curves less informative than the graphic sections from which they have been derived. It is, however, quite possible that students will enjoy publishing them, just as for many years they have enjoyed publishing 'norms' corresponding with analyses of igneous rocks.

I have mentioned the sequence, sandstone, shale, limestone, as a standard with which Lombard compares actual sequences. I have also indicated that he is prepared to admit intermediates, such as shaly sandstone, sandy shale, etc., in his scale. A problem is presented when the local sequence includes an item, say, coal, which cannot lithologically be placed in the standard succession. This particular difficulty is faced by Lombard in a section on "Séquences rhythmiques détritiques-colloïdales-calcaires à charbon", pp. 473–498, in which he takes most of his data from Moore's account of the Carboniferous in Texas and Robertson's of the same formation in Britain. In its simplest form the vertical sequence of rock types runs from older to younger as follows: sandstone, shale (more or less converted to root-bed), coal, shale, limestone, shale; sandstone again, with a similar repeat of the other terms. Lombard has not realized that the coal is an aerial formation, which places it outside his standard scale, intended for marine formations only. Accordingly, he inserts it between non-calcareous and calcareous shale, remarking that it has originated from fine plant debris.

Before leaving this subject I may add that I do not agree with Robertson's idea that the rhythm depends upon the intermittent rupture of a bar that normally excluded the sea from a low-level, subsiding, afforested marsh. It would require a pump. Peach's 1885 explanation involving recurrent speeding up of subsidence is much more acceptable.

E. B. Bailey

OUTLINE OF STEROID CHEMISTRY

The Chemistry of Steroids

By Dr. W. Klyne. (Methuen's Monographs on Biochemical Subjects.) Pp. 216. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1957.) 18*s.* net.

In the quarter of a century which has elapsed since the elucidation of the final features of the structures of the sterols and bile acids and the almost coincident recognition that an identical ring system occurred in the first of the sex hormones to be isolated, the chemistry of the steroids has undergone extensive development. Numerous new members of the group, many with the properties of hormones, have been isolated from animal sources, while a few types of important plant products, such as the cardiac glycosides, have been shown to contain the same characteristic ring system. Steroid chemistry has thus become a wide and specialized field.

Treatises on the subject, or on parts of it, are of course available, but these are mainly for the specialist. A brief survey of the whole field, such as is contained in the above volume, is therefore to be welcomed. That this work, dealing as it does with the purely chemical side of the subject, should appear in a well-known series of monographs on biochemical subjects might, at first sight, seem strange. But this anomaly finds its explanation in the author's statement that a companion volume, by another writer dealing with the biochemistry, is in course of preparation.

One aim of the book, namely, the provision of "an outline of the chemistry of the steroids for the non-chemical reader", has, in my view, not been achieved, and I doubt if such an end could be attained. Consequently, the few very elementary passages found interspersed in the text might well have been omitted. The subject-matter is not arranged for easy reading nor, as the author recognizes, is the treatment comprehensive. In my view, the work must be regarded as a masterly summarization and tabulation of the principal facts relating to the chemistry of the steroids. Thus, to take a random example from one of the less common steroids, if one wished to gain some information about stigmasterol one would find in Table 6A its systematic name, molecular formula and two physical constants. From the systematic name, and with the aid of the formula for cholesterol on p. 111, of the system of numbering for the nucleus given in the introduction and of the structure of the side chain reproduced on p. 112, one could write the complete structural formula for stigmasterol. Table 6A also gives the soya bean as its source, from which one could deduce that stigmasterol is probably a phytosterol. As a work of this nature, the book will be found to be a handy volume for the expert or semi-expert to have at his elbow when he wishes to refresh his memory about the accepted structure, configuration or conformation of a particular steroid.

The text is remarkably free from misprints, although the misspelling of the word stereochemistry in one place on the first page of the preface produces initially a bad impression. E. STEDMAN

RECENT RADIOBIOLOGY

Advances in Radiobiology

Proceedings of the Fifth International Conference on Radiobiology held in Stockholm on 15th–19th August, 1956. Edited by George Carl de Hevesy, Arne Gunnar Forssberg, and John D. Abbatt. Pp. xvi+503. (Edinburgh and London: Oliver and Boyd, Ltd., 1957.) 77*s.* 6*d.* net.

RADIOBIOLOGY is now a subject in its own right and the principle of holding an annual international conference is well established. The present volume contains the sixty-nine papers contributed to the 1956 conference in Stockholm, together with the resulting discussions. As is inevitable in an annual conference, many of the papers are rather scrappy accounts of incompleted work. Nevertheless, every radiobiologist will find at least some topics discussed which impinge directly or indirectly on his own interests. But whether the book will appeal to a wider audience is more doubtful. Not all branches of radiobiology are represented and the main themes in this conference were radiation chemistry, biochemical effects on enzymes and cell components, irradiation of single cells and parts of cells, effects on the hæmopoietic system, protection by chemical and cellular agents, and genetics.

Perhaps the most important new discovery is that if a suspension of spleen or bone-marrow cells is injected intravenously into a heavily irradiated mouse, some of the injected cells colonize and eventually entirely repopulate the radiation-depleted hæmopoietic tissues of the mouse, giving rise to what has come to be called a 'radiation chimera'. It had been known for some time that animals could be 'protected' from otherwise fatal doses of radiation by the post-irradiation injection of spleen or bone marrow and it was generally guessed that this was due to some chemical or humoral factor in the injected material. It has now been shown, however, by four different groups of workers, that the effective agent in the injected material is cellular rather than humoral, and that the injected living cells reach and eventually recolonize the bone marrow, spleen, lymph nodes and thymus of the irradiated animal. It has been found that even rat cells will repopulate the organs of the mouse, at any rate for a time. The most elegant and convincing of these demonstrations is that of Ford, Hamerton, Barnes and Loutit, which is fully reported in this volume. They were able to identify the transfused foreign donor cells by virtue of their chromosomal characters and to determine the proportion of these cells in the various hæmopoietic organs of the irradiated recipient. Important as this new discovery is for radiobiology, it also has some far-reaching implications and applications in the general field of biology. The whole subject of radioprotection by both chemical and cellular agents is admirably dealt with by Cohen, Vos and van Bekkum in a paper which deserves special mention.

Another new line of thought which emerges, particularly in the discussions, is the suggestion of Bacq and Alexander that the primary biochemical lesion produced by radiation may be a breaking of the hydrogen bonds which hold the individual enzymes together and in place in the cell. The enzymes are thus released from their normal sites in mitochondria or microsomes and escape into the general cytoplasm, where they proceed to attack various structures including the nucleus. More specifically, it has been shown that after irradiation deoxyribonuclease is liberated from the mitochondria and microsomes into the cytoplasm, and this could perhaps account for the nuclear changes which are the first visible signs of radiation damage.

Most of the biological effects of irradiation are assumed to result from an indirect action of radiation, in the sense that the primary ionizing action of the radiation is on the water, not on the cell proteins, etc. The free radicals produced by the ionization of water may then react with oxygen to produce even more toxic substances such as hydrogen peroxide. The chief evidence in support of this view has been the fact that the great majority of radiobiological effects are both oxygen- and temperature-dependent. Alexander has now shown, however, that when various polymers and also certain proteins are irradiated in the dry state the radiochemical changes produced are also oxygen- and temperature-dependent. As a result of this and other work more attention is now being paid to possible direct effects of radiation on the macromolecules of protein or deoxyribonucleic acid.

Little progress has been made in the search for radioprotective chemical substances. The sulphur compounds—cysteine, cysteamine, cystamine and certain thiuronium compounds—have not yet been bettered, but the mechanism by which they act is still hotly debated. The simple explanation that they all act by lowering the intracellular oxygen concentration seems no longer tenable. There is evidently still much to be learnt in this field and the outlook is not so discouraging as at one time appeared.

Irradiation of localized areas in single cells by a microbeam of α-particles has not so far given the clear-cut answers which were hoped for.

In the more medical field, Curtis and Healey find that animals receiving a dose of radiation as young adults undergo premature ageing quite apart from the increased incidence of tumours. Furthermore, in old age these animals are much less able to withstand a 'toxic stress' as, for example, the administration of typhoid vaccine or nitrogen mustard. Faber presents figures from the Danish health service which show an association between the incidence of chronic myeloid leukæmia and previous diagnostic radiography.

This volume is somewhat smaller than its predecessor but costs 23 per cent more. O. A. TROWELL

Handbook of Chemistry and Physics

A Ready-Reference Book of Chemical and Physical Data. Edited by Prof. Charles D. Hodgman, in association with Prof. Robert C. Weast and Dr. Samuel M. Selby. Thirty-ninth edition. Pp. xxii+3213. (Cleveland, Ohio: Chemical Rubber Publishing Company, 1957.) n.p.

LIKE the world's population, the size of reference books increases alarmingly from year to year. The "Handbook of Chemistry and Physics" is no exception. There are nearly two hundred contributors (living, emeritus and deceased) to the thirty-ninth edition, which runs to more than three thousand, two hundred pages, though some of these are reserved for future expansion. The book is, however, kept down to a manageable size by the use of India paper. Unfortunately, a solution along these lines is not possible where human populations are concerned.

The "Handbook" has appeared almost every year since 1914; this is in itself some indication of its success and usefulness. In each edition new information is added until now the amount it contains is really stupendous. Opening the index at random one finds such esoteric topics as Babo's law; concentration, freezing points and densities of calcium chloride brines; haversines, table; label protection; stain, acid proof, for wood; ultra-violet sensitization of photographic plates. There is something for everyone.

New tables in this edition include nuclear spin and moments; relative sensitivities (which relate the nuclear magnetic resonance of certain nuclides to that of the proton); superconductivities of metals, alloys and compounds; energy, mass and velocity relations to the electron; magnetic properties of transformer steels and high permeability materials; dielectric constants of pure liquids; dielectric constants and dipole moments of substances in the gaseous state. The information on isotopes has also been extended and revised and now goes up to element 101. There are four new tables on the sugars.

There is no doubt that having the "Handbook" to hand will save many a wearisome hunt in the library. It may also save something else: if you are quick enough after sucking a bit too hard while filling your pipette with 10*N* cyanide, just turn to p. xix and find out what to do.

The Study of Plant Communities

An Introduction to Plant Ecology. By Prof. Henry J. Oosting. Second edition. Pp. viii+440. (San Francisco, Calif.: W. H. Freeman and Company; London: Bailey Bros. and Swinfen, Ltd., 1956.) 6 dollars; 51*s*.

IN this second edition of Prof. Oosting's book the general plan remains unaltered, but the text has been brought up to date and many sections are entirely rewritten. Intended as an introduction to plant ecology for university students, the aim is admirably achieved, and the book contains much that is available otherwise only in more advanced texts. In this it well merits a place in the school library where botany is taught to scholarship-level. The discussion loses little for the British reader from being based on American plant communities, for the scope is wide, and good illustrations make up for the unfamiliarity of the plants referred to.

The opening section deals with the nature of plant communities and the techniques for sampling and describing them. A chapter on the objectives and methods of the European phytosociological school is welcome, for, with the divergence of aim in the trend that British ecology has followed, we have tended to lose contact with those aspects of Continental work which can be of help to us. The ensuing five chapters deal generally with environmental factors controlling the community, and the standard techniques for their measurement. In the section on community dynamics the chapter on plant succession has been rewritten to give a clear summary of the monoclimax and polyclimax interpretations of vegetation. Climax regions of North America are then described, and the final chapter deals with the applications of ecology to practical problems of forestry, pasture management, erosion control and land utilization.

A list of books for wider reading is given with each chapter, and there is a good bibliography of original references, including a fair sprinkling of European papers. MAURICE ASHBY

Automatic Control

(A *Scientific American* Book.) Pp. x+148. (London: G. Bell and Sons, Ltd., 1957.) 10*s*. 6*d*. net.

THIS book was first published in the United States in 1955 and the format immediately strikes one as American, particularly the rather crude illustrations. On looking a little closer, one finds that it is a series of popular articles covering all the essential aspects of automatic control, by authors of international repute. This led to the expectation of nothing more than a hotch-potch of disconnected 'potboilers'. However, on reading it, this proved to be quite unjust to both publishers and authors, for as might be expected of such authors as Gordon Brown, Arnold Tustin, Grey Walter and Warren Weaver, the chapters are all written with great care to give the general reader a clear and accurate picture of some of the most recent developments.

Although there is no apparent connexion between the chapters, together they cover all the important aspects of this wide and difficult field. The theory of control; mechanical, hydraulic and other control systems; chemical plant, machine tools and the automatic office; information theory and the physiological comparisons between man and machines are all covered. Even the economic impact of automation has been included in a short but informative article by Wassily Leontief.

As a book, it has the great merit of being short. Covering such a wide field in less than 150 pages, it cannot go very deep; but it goes deep enough for the average reader, whether scientific or non-technical. The illustrations, which are ugly to look at because crudely drawn, have the great merit of clarity. It is a pity that such excellent letterpress has not been set in a more pleasing type.

J. F. COALES

Selected Papers in Statistics and Probability

By Abraham Wald. Second printing. Pp. ix+702. (Stanford, Calif.: Stanford University Press; London: Oxford University Press, 1957.) 80*s*. net.

THIS volume contains 51 papers on probability and statistics by Abraham Wald, who met an untimely and much lamented death in an air-crash in 1950. The first printing, edited for the Institute of Mathematical Statistics by a number of distinguished statisticians, was published by McGraw-Hill in 1955. It was rapidly exhausted and this second printing, issued by the Stanford University Press, will be very welcome.

A THREE-DIMENSIONAL MODEL OF THE MYOGLOBIN MOLECULE OBTAINED BY X-RAY ANALYSIS

By DRS. J. C. KENDREW, G. BODO, H. M. DINTZIS, R. G. PARRISH and H. WYCKOFF
Medical Research Council Unit for Molecular Biology, Cavendish Laboratory, Cambridge
AND
D. C. PHILLIPS
Davy Faraday Laboratory, The Royal Institution, London

MYOGLOBIN is a typical globular protein, and is found in many animal cells. Like hæmoglobin, it combines reversibly with molecular oxygen; but whereas the role of hæmoglobin is to transport oxygen in the blood stream, that of myoglobin is to store it temporarily within the cells (a function particularly important in diving animals such as whales, seals and penguins, the dark red tissues of which contain large amounts of myoglobin, and which have been our principal sources of the protein). Both molecules include a non-protein moiety, consisting of an iron–porphyrin complex known as the hæm group, and it is this group which actually combines with oxygen; hæmoglobin, with a molecular weight of 67,000, contains four hæm groups, whereas myoglobin has only one. This, together with about 152 amino-acid residues, makes up a molecular weight of 17,000, so that myoglobin is one of the smaller proteins. Its small size was one of the main reasons for our choice of myoglobin as a subject for X-ray analysis.

In describing a protein it is now common to distinguish the primary, secondary and tertiary structures. The *primary structure* is simply the order, or sequence, of the amino-acid residues along the polypeptide chains. This was first determined by Sanger using chemical techniques for the protein insulin[1], and has since been elucidated for a number of peptides and, in part, for one or two other small proteins. The *secondary structure* is the type of folding, coiling or puckering adopted by the polypeptide chain: the α-helix and the pleated sheet are examples. Secondary structure has been assigned in broad outline to a number of fibrous proteins such as silk, keratin and collagen; but we are ignorant of the nature of the secondary structure of any globular protein. True, there is suggestive evidence, though as yet no proof, that α-helices occur in globular proteins, to an extent which is difficult to gauge quantitatively in any particular case. The *tertiary structure* is the way in which the folded or coiled polypeptide chains are disposed to form the protein molecule as a three-dimensional object, in space. The chemical and physical properties of a protein cannot be fully interpreted until all three levels of structure are understood, for these properties depend on the spatial relationships between the amino-acids, and these in turn depend on the tertiary and secondary structures as much as on the primary.

Only X-ray diffraction methods seem capable, even in principle, of unravelling the tertiary and secondary structures. But the great efforts which have been devoted to the study of proteins by X-rays, while achieving successes in clarifying the secondary (though not yet the tertiary) structures of fibrous proteins, have hitherto paid small dividends among the metabolically more important globular, or crystalline, proteins. Progress here has been slow because globular proteins are much more complicated then the organic molecules which are the normal objects of X-ray analysis (not counting hydrogens, myoglobin contains 1,200 atoms, whereas the most complicated molecule the structure of which has been completely determined by X-rays, vitamin B_{12}, contains 93). Until five years ago, no one knew how, in practice, the complete structure of a crystalline protein might be found by X-rays, and it was realized that the methods then in vogue among protein crystallographers could at best give the most sketchy indications about the structure of the molecule. This situation was transformed by the discovery, made by Perutz and his colleagues[2], that heavy atoms could be attached to protein molecules in specific sites and that the resulting complexes gave diffraction patterns sufficiently different from normal to enable a classical method of structure analysis, the so-called 'method of isomorphous replacement', to be used to determine the relative phases of the reflexions. This method can most easily be applied in two dimensions, giving a projection of the contents of the unit cell along one of its axes. Perutz attached a *p*-chloromercuri-benzoate molecule to each of two free sulphydryl groups in hæmoglobin and used the resulting changes in certain of the reflexions to prepare a projection along the *y*-axis of the unit cell[3]. Disappointingly, the projection was largely uninterpretable. This was because the thickness of the molecule along the axis of projection was 63 A. (corresponding to some 40 atomic diameters), so that the various features of the molecule were superposed in inextricable confusion, and even at the increased resolution of 2·7 A. it has proved impossible to disentangle them[4]. It was clear that further progress could only be made if the analysis were extended to three dimensions. As we shall see, this involves the collection of many more observations and the production of three or four different isomorphous replacements of the same unit cell, a requirement which presents great technical difficulties in most proteins.

The present article describes the application, at low resolution, of the isomorphous replacement method in three dimensions to type *A* crystals of sperm whale myoglobin[5]. The result is a three-dimensional Fourier, or electron-density, map of the unit cell, which for the first time reveals the general nature of the tertiary structure of a protein molecule.

Isomorphous Replacement in Myoglobin

No type of myoglobin has yet been found to contain free sulphydryl groups, so that the method of attaching heavy atoms used by Perutz for hæmoglobin could not be employed. Eventually, we were able to attach several heavy atoms to the myoglobin molecule at different specific sites by crystallizing it with a variety of heavy ions chosen because they might be expected, on general chemical grounds, to possess affinity for protein side-chains. X-ray, rather than chemical, methods were used to determine whether combination had taken place, and, if so, whether the ligand was situated predominantly at a single site on the surface of the molecule. Among others, the following ligands were found to combine in a way suitable for the present purpose: (i) potassium mercuri-iodide and auri-iodide; (ii) silver nitrate, potassium auri-chloride; (iii) *p*-chloromercuri-benzene sulphonate; (iv) mercury diammine ($Hg(NH_3)^{2+}$, prepared by dissolving mercuric oxide in hot strong ammonium sulphate), *p*-chloro-aniline; (v) *p*-iodo-phenylhydroxylamine. Each group of ligands combined specifically at a particular site, five distinct sites being found in all. The substituted phenylhydroxylamine is a specific reagent for the iron atom of the hæm group[6], and may be assumed to combine with that group; in none of the other ligands have we any certain knowledge of the mechanism of attachment or of the chemical nature of the site involved.

Methods of X-ray Analysis

Type *A* crystals of myoglobin are monoclinic (space group $P2_1$) and contain two protein molecules per unit cell. Only the $h0l$ reflexions are 'real', that is, can be regarded as having relative phase angles limited to 0 or π, or positive or negative signs, rather than general phases; when introduced into a Fourier synthesis, these reflexions give a projection of the contents of the cell along its y-axis. In two dimensions the analysis followed lines[7] similar to that of hæmoglobin. First, the heavy atom was located by carrying out a so-called difference-Patterson synthesis; if all the heavy atoms are located at the same site on every molecule in the crystal, this synthesis will contain only one peak, from the position of which the x- and z-co-ordinates of the heavy atom can be deduced, and the signs of the $h0l$ reflexions determined. These signs were cross-checked by repeating the analysis for each separate isomorphous replacement in turn; we are sure of almost all of them to a resolution of 4 A., and of most to 1·9 A. Using the signs, together with the measured amplitudes, we may, finally, compute an electron-density projection of the contents of the unit cell along y; but, as in hæmoglobin and for the same reasons, the projection is in most respects uninterpretable (even though here the axis of projection is only 31 A.). On the other hand, knowledge of the signs of the $h0l$ reflexions to high resolution enabled us to determine the x- and z-co-ordinates of all the heavy atoms with some precision. This was the starting point for the three-dimensional analysis now to be described.

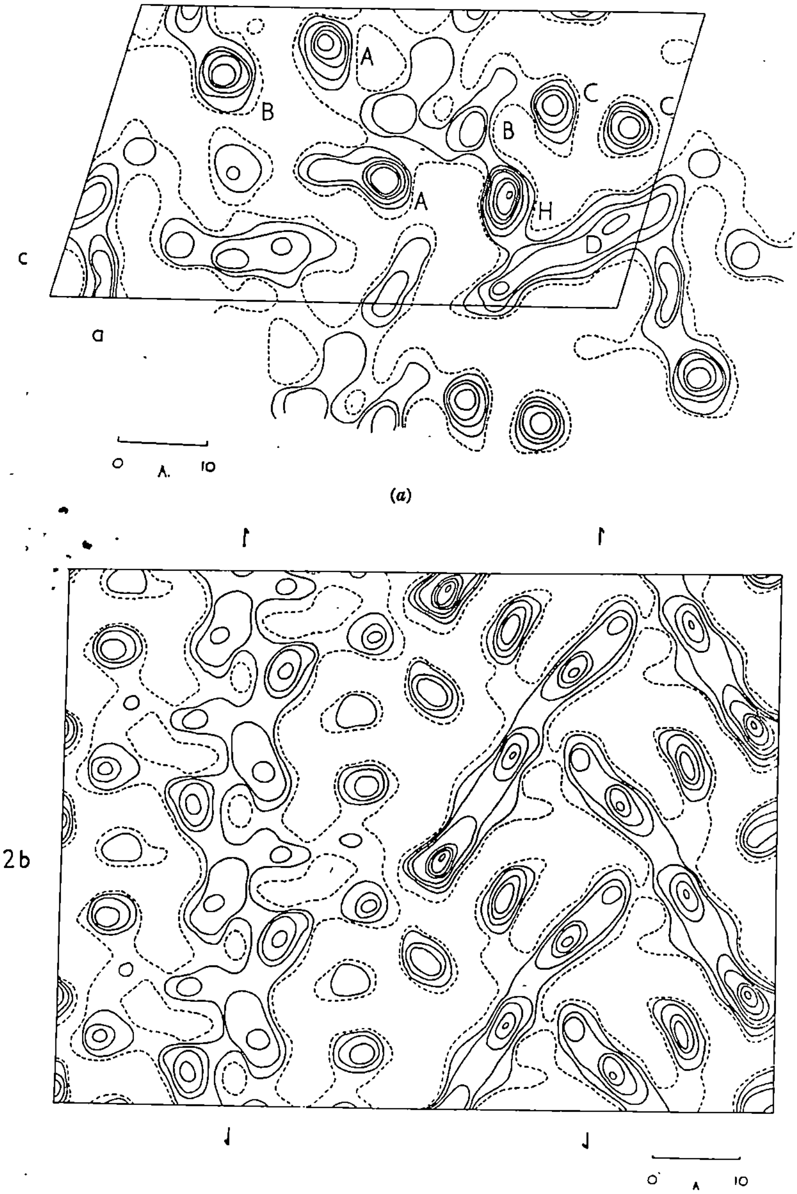
In three dimensions the procedure is much more lengthy because all the general reflexions hkl must be included in the synthesis, and more complicated because these reflexions may have any relative phase angles, not only 0 or π. Furthermore, we need to know all three co-ordinates of the heavy atoms; the two-dimensional analysis gives x and z, but to find y is more difficult, and details of the methods used will be published elsewhere, including among others two proposed by Perutz[8] and one proposed by Bragg[9]. Finally, a formal ambiguity enters into the deduction of general phase angles if only one isomorphous replacement is available; this can be resolved by using several replacements[10], such as are available in the present case. Once the phases of the general reflexions have been determined, one can carry out a three-dimensional Fourier synthesis which will be a representation of the electron density at every point in the unit cell.

Before such a programme is embarked upon, however, the resolution to be aimed at must be decided. The number of reflexions needed, and hence the amount of labour, is proportional to the cube of the resolution. To resolve individual atoms it would be necessary to include at least all terms of the series with spacings greater than 1·5 A.—some 20,000 in all; and it is to be remembered that the intensities of all the reflexions would have to be measured for *each* isomorphous derivative. Besides this, introduction of a heavy group may cause slight distortion of the crystal lattice; as the resolution is increased, this distortion has an increasingly serious effect on the accuracy of phase determination. In the present stage of the analysis the most urgent objective was an electron-density map detailed enough to show the general layout of the molecule—in other words, its tertiary structure. If the α-helix, or something like it, forms the basis of the structure, we need only work to a resolution sufficient to show up a helical chain as a rod of high electron density. For this purpose we require only reflexions with spacings greater than about 6 A.; in all there are some 400 of these, of which about 100 are $h0l$'s already investigated in the two-dimensional study. The Fourier synthesis described here is computed from these 400 reflexions only, and is in consequence blurred; besides this, it is distorted by an unknown amount of experimental error, believed to be small but at the moment difficult to estimate. Thus while the general features of the synthesis are undoubtedly correct, there may be some spurious detail which will require correction at a later stage.

The Three-dimensional Fourier Synthesis

The synthesis was computed in 70 min. on the EDSAC Mark I electronic computer at Cambridge (as a check, parts of the computation were repeated on DEUCE at the National Physical Laboratory). It is in the form of sixteen sections perpendicular to y and spaced nearly 2 A. apart; these must be piled on top of one another to represent the electron density throughout the cell, containing two myoglobin molecules together with associated mother liquor (which amounts to nearly half the whole). Unfortunately, the synthesis cannot be so represented within the two-dimensional pages of a journal; furthermore, if the sections are displayed side by side, they give no useful idea of the structure they represent. The examples reproduced in Fig. 1 illustrate some of the more striking features.

A first glance at the synthesis shows that it contains a number of prominent rods of high electron density; these usually run fairly straight for distances of 20, 30 or 40 A., though there are some curved ones as well. Their cross-section is generally nearly circular, their diameter about 5 A., and they tend to lie at distances from their neighbours of 8–10 A. (axis to axis). In some instances two segments of rod are joined by fairly sharp corners. Fig. 1*a*



(a)

(b)

Fig. 1. (a) Section of three-dimensional Fourier synthesis of type *A* myoglobin at $y = -1/8\ b$. *A–D*, polypeptide chains; *H*, hæm group. (b) Section parallel to [20$\bar{1}$] at $x = 0$, showing polypeptide chain *A* (on the right)

shows several rods—three of them (*A*, *B* and *C*) cross the plane of the section almost at right angles, while one (*D*) lies nearly in that plane. *D* is part of a nearly straight segment of chain about 40 A. long, of which some 20 A. is visible in this section. It seems virtually certain that these rods of high density are the polypeptide chains themselves—indeed, it is hard to think of any other features of the structure which they could possibly be. Their circular cross-section is what would be expected if the configuration were helical, and the electron density along their axes is of the right order for a helical arrangement such as the α-helix. The various rods in the structure are intertwined in a very complex manner, the nature of which we shall describe later.

Another prominent feature is a single disk-shaped region of high electron density which reaches a peak value greater than at any other point in the cell. A section through this disk is shown at *H* in Fig. 1*a*. We identify this feature as the hæm group itself, for the following reasons: (i) the hæm group is a flat disk of about the same size; (ii) its centre is occupied by an iron atom and therefore has a higher electron density than any other point in the whole molecule; (iii) a difference-Fourier projection of the *p*-iodophenylhydroxylamine derivative shows that, at least in *y*-projection, the position of the iodine atom is near that of our group; this is what we should expect, since this reagent specifically combines with the hæm group; (iv) the orientation of the disk corresponds, as closely as the limited resolution of the map allows one to determine it, with the orientation of the hæm group deduced from measurements of electron spin resonance[6,11].

We cannot understand the structure of the molecules in the crystal unless we can decide where one ends and its neighbours begin. In a protein crystal the interstices are occupied by mother liquor, in this case strong ammonium sulphate, the electron density of which is nearly equal to the average for the whole cell. Hence it is to be expected that in the intermolecular regions the electron density will be near average (the density of coiled polypeptide chains is much above average, and that of side-chains well below). It should also be fairly uniform; these regions should not be crossed by major features such as polypeptide chains. Using these criteria, it is possible to outline the whole molecule with minor uncertainties. It was gratifying to find that the result agreed very well, in projection, with a salt-water difference-Fourier projection made as part of the two-dimensional programme (for the principles involved, see ref. 12). Moreover, the dimensions of the molecule agreed closely with those deduced from packing considerations in various types of unit cell.

The Myoglobin Molecule

We are now in a position to study the tertiary structure of a single myoglobin molecule separated from its neighbours. Fig. 2 illustrates various views of a three-dimensional model constructed to show the regions of high electron density in the isolated molecule. Several points must be noticed. First, the model shows only the general distribution of dense regions. The core of a helical polypeptide chain would be such a region; but if the chain were pulled out, into a β-configuration, for example, its mean density would drop to near the average for the cell and the chain would fade out at this resolution.

Similarly, side-chains should, in general, scarcely show up, so that the polypeptide rods in the model must be imagined as clothed in an invisible integument of side-chains, so thick that neighbouring chains in reality touch. Third, features other than polypeptide chains may be responsible for some of the regions of high density; patches of adsorbed salt, for example. Fourth, the surface chosen to demarcate a molecule cannot be traced everywhere with certainty, so it is possible that the molecule shown contains parts of its neighbours, and correspondingly lacks part of its own substance.

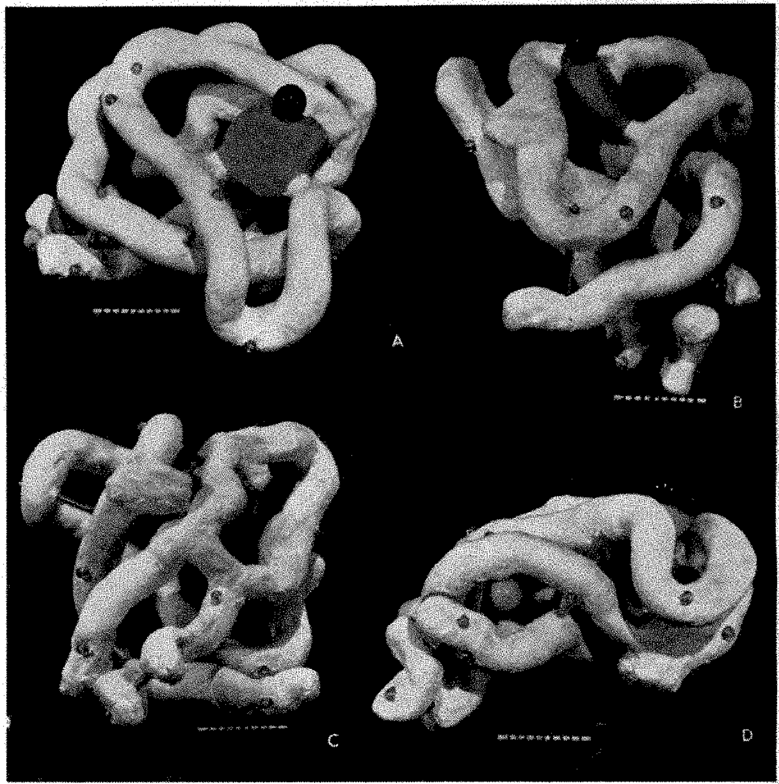


Fig. 2. Photographs of a model of the myoglobin molecule. Polypeptide chains are white; the grey disk is the hæm group. The three spheres show positions at which heavy atoms were attached to the molecule (black: Hg of *p*-chloro-mercuri-benzene-sulphonate; dark grey: Hg of mercury diammine; light grey: Au of auri-chloride). The marks on the scale are 1 A. apart

Making due allowance for these difficulties, we may note the main features. It is known[13] that myoglobin has only one terminal amino-group: it is simplest to suppose that it consists of a single polypeptide chain. This chain is folded to form a flat disk of dimensions about 43 A. × 35 A. × 23 A. Within the disk chains pursue a complicated course, turning through large angles and generally behaving so irregularly that it is difficult to describe the arrangement in simple terms; but we note the strong tendency for neighbouring chains to lie 8–10 A. apart in spite of the irregularity. One might loosely say that the molecule consists of two layers of chains, the predominant directions of which are nearly at right angles in the two layers. If we attempt to trace a single continuous chain throughout the model, we soon run into difficulties and ambiguities, because we must follow it around corners, and it is precisely at corners that the chain must lose the tightly packed configuration which alone makes it visible at this resolution (an α-helix, for example, cannot turn corners without its helical configuration being disrupted). Also, there are several apparent bridges between neighbouring chains, perhaps due to the apposition of bulky side-chains. The model is certainly compatible with a single continuous chain, but there are at least two alternative ways of tracing it through the molecule, and it will not be possible to ascertain which (if either) is correct until the resolution has been improved. Of the secondary structure we can see virtually nothing directly at this stage. Owing to the corners, the chain cannot be in helical configuration throughout; in fact, the total length of chain in the model is 300 A., whereas an α-helix of 152 residues would be only 228 A. long. The 300 A. might correspond, for example, to 70 per cent α-helix and 30 per cent fully extended chain, but of course intermediate configurations are probably present, too. The hæm group is held in the structure by links to at least four neighbouring chains; nevertheless, one side of it is readily accessible from the environment to oxygen and to larger reagents such as *p*-iodo-phenylhydroxylamine (in the difference-Fourier projection of this complex, referred to above, the position of the iodine atom indicates that the ligand is attached to the outside of the group). Clearly, however, the model cannot at present be correlated in detail with what we know of the chemistry of myoglobin; this must await further refinement.

Perhaps the most remarkable features of the molecule are its complexity and its lack of symmetry. The arrangement seems to be almost totally lacking in the kind of regularities which one instinctively anticipates, and it is more complicated than has been predicated by any theory of protein structure. Though the detailed principles of construction do not yet emerge, we may hope that they will do so at a later stage of the analysis. We are at present engaged in extending the resolution to 3 A., which should show us something of the secondary structure; we anticipate that still further extensions will later be possible—eventually, perhaps, to the point of revealing even the primary structure.

Full details of this work will be published elsewhere. We wish to record our debt to Miss Mary Pinkerton for assistance of all kinds; to the Mathematical Laboratory, University of Cambridge, for computing facilities on the EDSAC; to Dr. J. S. Rollett and the National Physical Laboratory for similar facilities on the DEUCE; to Mrs. Joan Blows and Miss Ann Mansfield for assistance in computing; for fellowships to the U.S. Public Health Service (H. W.), the Merck Fellowship Board (R. G. P.), the U.S. National Science Foundation (R. G. P. and H. M. D.), and the Rockefeller Foundation (H. M. D.); and to Sir Lawrence Bragg for his interest and encouragement. Finally, we wish to

express our profound gratitude to the Rockefeller Foundation, which has actively supported this research from its earliest beginnings.

RECENT CLIMATIC CHANGES

By DR. E. B. KRAUS

Snowy Mountains Hydro-Electric Authority, Cooma North, New South Wales, Australia

CLIMATE is nowhere invariant. The existence of a never-ending change is most apparent along the shifting boundaries of the various climatic provinces. During the past few hundred years the boundaries of the Alpine and Sub-Arctic regions have experienced some striking changes in glaciation and considerable variations in the extent and the seasonal duration of sea ice. It has now been established from the analysis of rainfall and stream-flow records that fluctuations of corresponding or even larger amplitude occurred in the sub-tropics at the boundary of the arid zone. During the same time the climates of the Antarctic ice cap, the central Sahara or the Amazon rain forest may not have altered a great deal.

Changes in a time series can be illustrated to advantage by graphs of cumulative percentual deviations from a mean. Graphs of this type accentuate changes in a time series, while running averages or orthodox statistical analyses tend to smooth them out. They demonstrate, at a glance, the existence of a trend and the time when it changes.

In the following diagrams (Figs. 1–6), the ordinate:

$$y(n) = 100 \sum_{l=1881}^{n} \left(\frac{r_l}{\bar{r} - 1}\right)$$

where n represents the running calendar year, r_l the rainfall or stream discharge for the year l, and $\bar{r}$ the mean for the years 1881–1940. It is easily seen that y must be zero at the beginning of 1881 and the end of 1940. The graph of y rises for $r_l > \bar{r}$ and vice versa. It will be concave upwards during periods when r is increasing with time and convex when it is decreasing. The percentual deviation from $\bar{r}$ of the mean for any other period, say the years n to $(n + m)$, is given simply by $[y\ (n + m) - y(m)]/m$.

The accompanying six diagrams have been brought together to demonstrate how fluctuations of the same type occur at about the same time all around the globe. Fig. 1 illustrates the changes which occurred in the rainfall regime of semi-arid, north-western New South Wales (Australian rainfall district No. 48). It can be deduced from the curve that the mean rainfall for the years 1879–97 was 26 per cent above the 1881–1940 average. It was 11 per cent below that average during the period 1898–1946. In absolute terms, the mean annual rainfall from the beginning of records to 1897 was 16·90 in.; during the following forty-nine years it was 12·02 in. During the past ten years conditions were again more similar to those of the nineteenth century.

Fig. 2 deals with the east coast of Queensland (Australian rainfall district No. 40). The rainfall there is more seasonal but also more than three times as heavy as in north-western New South Wales. The onset of the dry period occurred two years later. It was interrupted by wetter conditions after about 1923, though a second severe drought occurred in the late '30's and early 1940's.

Conditions on the east coast of North America are illustrated by Fig. 3, which gives the mean rainfall for Charleston and Cape Hatteras. In an earlier paper[4] it had been shown that fluctuations there were paralleled by the records of other stations along the American east coast, and that the records suggest the persistence of relatively wet conditions all through the nineteenth and the later eighteenth centuries.

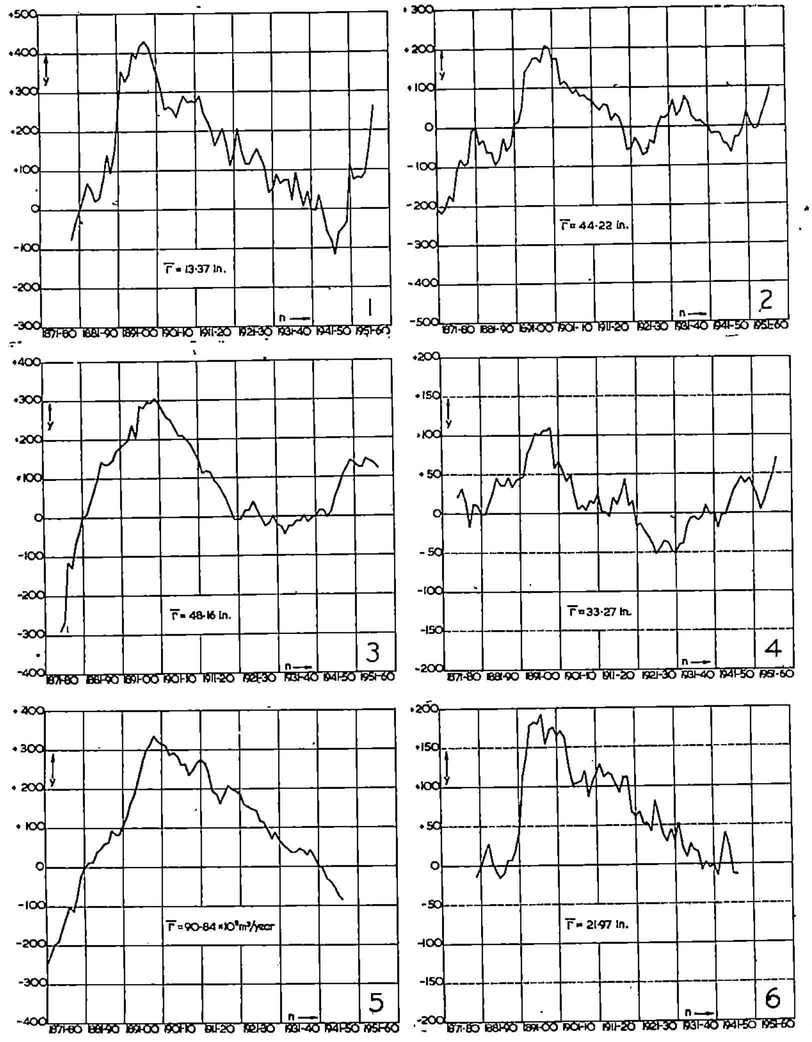
Fig. 4 shows the changes which occurred in the space-average of a large number of rainfall stations used by the Indian Meteorological Service to evaluate and forecast monsoon rainfall over the Indian peninsula. The change in the rainfall regime there was comparatively small and the vertical scale of the diagram has therefore been doubled. The same pattern of change with somewhat larger amplitude occurred in the more arid districts of north-west India and West Pakistan. All over this region the dry period which began at the end of the past century was ameliorated or terminated by about 1910.

Fig. 5 treats the discharge of the Nile at Aswan in a similar way. The difference in the mean discharge before and after 1898 amounts, in this case, to more than 30 per cent or 27 × 10^9 m.^{3}/year.

The changes which occurred in parts of South Africa are illustrated by Fig. 6, which represents the South African rainfall district No. 16*A* in the Central Cape Province. Unfortunately, data after 1946 were not available in Australia for the two African cases.

Arakawa[1] and I have shown that changes similar to those demonstrated here have occurred in maritime parts of East Asia and in the West Indies, Hawaii and other tropical stations. They can also be found in Rhodesian rainfall records. Together, this material would seem to prove the existence of parallel and rather abrupt climatic fluctuations over a large part of the Earth.

The amplitude of the change in rainfall regime was largest at the fringes of the arid zone. In the extreme case of Aden, the rainfall record shows a difference of 84 per cent between the means for the thirty years after 1894 and the preceding thirteen years of avail-



Figs. 1–6. Cumulative percentual deviations from the 1881–1940 annual mean. (1) N.W. New South Wales (Australian rainfall district No. 48); (2) Queensland Coast (Australian rainfall district No. 40); (3) Carolina Coast (mean of Charleston and Cape Hatteras); (4) India (peninsula); (5) Nile discharge at Aswan; (6) Central Cape Province (South Africa Rainfall District No. 16A)

able records. The change is also well marked along the sub-tropical east coasts of North America and Australia. In the humid tropics it appears to have been restricted to the beginning or end of the rainy seasons. Similarly, in the sub-tropical transition regions, where rain may fall both summer and winter, the same pattern of change may be restricted to the intermediate seasons of autumn and spring. The curves of cumulative deviations from the mean for these seasons for some parts of Australia and South Africa are parallel to those shown for annual rainfall and stream-flow in the present article. In some cases they show extremely large amplitudes, though the changes in annual rainfall were comparatively insignificant.

A more detailed analysis indicates that the onset of dry conditions at the end of the past century was associated with a widening of the arid zone, mainly at the expense of the equatorial summer-rainfall belt. This produced a wider separation in space and time of summer- and winter-rainfall regimes. As rain in many sub-tropical regions is associated with the seasonal migration of the equatorial rainfall belt, the narrowing of this belt caused rainy seasons to become shorter.

The observable sequence of events began in 1894 with a failure of spring rains in the 'transition' regions of South Africa and Australia. A prolonged drought commenced in 1895 on the equatorial fringes of the arid zones. From 1899 onwards dry conditions affected both the east coast of the continents and wet tropical regions with pronounced seasonal rainfall regimes. In 1902 a sudden onset of warmer conditions can be observed in the temperature records of many stations in temperate regions, demonstrated for Edinburgh, for example, by Veryard[7]. An accelerated recession of glaciers has also been reported to have started at the beginning of the century. By 1910 the seasonal pressure fluctuations associated with the Asiatic monsoon began to increase in amplitude, resulting in a return to somewhat moister conditions in India[5].

To interpret the sequence it should be considered that in spite of the marked change of rainfall in low latitudes, no corresponding change can be discerned in higher latitudes. The decrease of rainfall in low latitudes must therefore have been associated with reduced evaporation. There is no evidence of a change in solar radiation at sea-level; in fact, the decrease in rainfall may well have been associated with a decrease in cloudiness. As a result of reduced evaporation, the sea surface should have become warmer. Transport of warmer water to higher latitudes may have contributed to the temperature increases and accelerated glacier recessions there, at the beginning of the century. By 1910 the heating of the Arctic may have progressed sufficiently to cause a weakening of the zonal atmospheric circulation which would permit a stronger development of the monsoon.

Evaporation from the sea depends on the wind strength. The trade-wind circulation is largely driven by a heat source associated with the liberation of latent heat in precipitation, and by a cold source associated with radiational cooling in the free atmosphere. The intensity and the difference in the level of these two sources determine the efficiency of the conversion of thermal into kinetic energy, and hence the strength of the trade circulation.

Both the height and the intensity of radiational cooling from the troposphere are affected to some small extent by ozone. Plass[8] calculated that comparatively minor changes in the ozone distribution could change the equilibrium temperature at the ground and at the top of cloud banks by more than 2 deg. C. In the free troposphere the heating and cooling rates due to ozone amount only to a few tenths of a degree per day, but even that may be sufficient to affect the trade circulation, which is a rather finely balanced process. The ozone layer in high latitudes is so thick that its upper strata shield it effectively against most solar influences. Changes in the ozone distribution there are mainly associated with vertical motion in the troposphere below. Near the equator the ozone is more likely to be affected directly by possible changes in ultra-violet solar radiation. Increases in short-wave radiation would tend to cause some heating and possible lowering of the tropical ozonosphere. This in turn would reduce radiational cooling in the troposphere and so decrease the efficiency of the trade circulation. It may be shown that if this effect exists, sudden changes in the tropical radiation balance would tend to cause disturbances in the atmospheric circulation pattern some two or three weeks later. This is supported by some observational evidence.

Menzel[6] and Bell[6] have discussed another possible mechanism of solar – weather relationships. They quote Craig, who found a statistically significant association of magnetic perturbations with pressure rises at 60–70° N. and pressure falls at about 40° N. It is assumed that such a pressure change would tend to oppose the accumulation of cold surface air in the Arctic. Magnetic disturbances are caused by corpuscular streams. Menzel indicates that the incoming stream may at times carry an energy density which over a limited area can be equivalent to that of solar radiation itself, and that this should cause intense heating of the surrounding atmospheric regions. Bell suggests that this causes the reported statistical changes in surface pressure. It is difficult to conceive a physical mechanism which would link high-level heating in the auroral zone with mass movements in the troposphere. If the mechanism stipulated by Miss Bell does in fact exist, it would act parallel to the one outlined above for the tropics. The increased solar activity would then tend to favour penetration of warm air into high latitudes on one hand; on the other, it would be associated with a less efficient trade circulation, decreased evaporation and a narrowed tropical rainbelt.

The tropospheric radiation balance is also affected by dust. Variations in dust content may affect in addition the available number of freezing nuclei. However, the decrease in rainfall at the end of the past century cannot be readily associated with the date of any major volcanic eruption or known change in meteoric activity; nor can this be done for the recent widespread increase in precipitation. Furthermore, these rainfall changes affected only a limited part of the globe. This seems to exclude explanations of climatic change primarily in terms of a changing number of atmospheric freezing nuclei.

To summarize: precipitation in the sub-tropics was generally above the 1881–1940 mean during the recorded part of the nineteenth century. A dry period associated with a widening of the arid belts set in abruptly at the end of the century. This lasted with only short interruption until a return of consistently wetter conditions in recent years. In several stations at the fringes of the arid zone the changes of long-term means amounted to more than 30 per cent. In climatically corresponding locations the change occurred simultaneously north and south of the equator. Tentative explanations in terms of variable solar activity are possible, but they cannot be substantiated without continuing quantitative measurements of the Sun and the upper air.

The large simultaneous change which occurred at the end of the past century at the fringes of the arid zone passed comparatively unnoticed. With the present more intensive development of marginal resources the economic effects of a similar change would be more apparent. In the case of Japan, this has been demonstrated rather strikingly by Arakawa[2]. Records of rainfall, stream flow, flood incidence, etc., which cover a limited period only, must not be used uncritically as a basis for planning costly developments of marginal water resources. The study of climatic fluctuations has therefore concrete practical implications, besides bearing upon knowledge of the past and upon interpretation of our present physical environment.

District rainfall values were made specially available by the Directors of the Australian and Indian Meteorological Services; this is gratefully acknowledged.

OBITUARY

Dr. A. V. Few

By the death of Dr. A. V. Few on December 24 from poliomyelitis, after a very short illness, research work on the surface chemistry of biological systems has lost one of its foremost younger workers.

Alan Victor Few was born on December 28, 1926, and was educated at Alleyn's School, Dulwich (1937–43), and then at Battersea Polytechnic, London, where in 1946 he graduated in chemistry, obtaining the B.Sc. (Special) degree with first-class honours. After a short spell in industry, he returned to Battersea in 1947 and worked with Dr. J. W. Smith. In 1949 he obtained the Ph.D. degree at the University of London for his work on the "Molecular Polarization of Amines in Solution".

However, his future interest in research was determined in 1949, when he moved to the Wright-Fleming Institute of Microbiology. Here he commenced to work on the physical chemistry of bacterial cells with Drs. P. D. Cooper and D. Rowley, work which led to the investigation of the mode of action of penicillin with the cell wall of *Staphylococcus aureus*, and emphasized the importance of studying the surface chemical properties of penicillin salts. In 1951 he moved to the Department of Colloid Science, Cambridge, with a grant from the Medical Research Council, where in the group under the direction of Dr. J. H. Schulman he commenced to study in detail the interaction of antibiotics with bacterial surfaces using surface-chemical techniques. As well as penicillin, the action of polymyxins was studied, and by the use of a low-pressure surface balance, with salt solutions as substrate, the molecular weights of polymyxins *A*, *B*, *D* and *E* were determined. In 1953 he was awarded the Ph.D. degree of the University of Cambridge for a thesis entitled "The Surface Chemistry of Certain Antibiotics".

This work had merely acted as an *apéritif*, and on his appointment to the external staff of the Medical Research Council, he proceeded with great enthusiasm to study the interaction of many other compounds with bacterial surfaces, and with cell extracts. His most recent work included investigations on the behaviour of the cyclic polypeptides, tyrocidine and gramicidin *S* at the air–water interface, the binding of surface-active agents by proteins, and an extensive study with Dr. A. R. Gilby of the interaction of surface-active agents with bacterial surfaces.

A modest man of charming disposition, he was an enthusiastic and determined research worker, always willing to discuss problems with junior workers and to give advice when consulted. He will be remembered with great affection by his colleagues and collaborators. His untimely death at an early age has robbed surface chemistry of a very active and promising worker.

His marriage to Gwendolen Mary Crookenden in 1949 was a very happy one, and there can be no doubt that his happy home-life contributed greatly to his research. He is survived by his wife and two young daughters.

R. H. OTTEWILL

University College of Science
Physics Dept.

NEWS and VIEWS

Commonwealth Trans-Antarctic Expedition

THE Commonwealth Trans-Antarctic Expedition led by Dr. Vivian Fuchs arrived at Scott Base on the Ross Sea at 1.47 p.m. on March 1, having completed the "last great journey in the world". The expedition has crossed the Antarctic Continent from Shackleton Base on the Weddell Sea, a distance of 2,150 miles, in ninety-nine days. The purpose of the journey has been to conduct a programme of scientific observations including seismic soundings, gravimetric readings, and meteorological observations in connexion with the International Geophysical Year. The survey party was accompanied by Sir Edmund Hillary, who met Dr. Fuchs at Depot 700, the last of the chain of five depots of food and fuel, established earlier between Scott Base and the South Pole. The other members of the expedition are: Warrant-Officer Roy Homard, engineer (Brixton); Ralph Lenton, wireless operator and carpenter (Coulsdon, Surrey); George Lowe, photographer (Hastings, New Zealand); David Pratt, engineer and transport officer (Bournemouth); Allan Rogers, medical officer (University of Bristol); David Stratton, surveyor and second in command of the team (London); Johannes la Grange, meteorologist (Keighley); and Geoffrey Pratt, physicist (Richmond, Surrey). They were met by vehicles and sledges manned by the New Zealand party which set out from Scott Base to accompany the expedition for the last mile or so. Dr. Fuchs was greeted at Scott Base by congratulatory messages from scientific and geographic institutions throughout the world, and from the prime ministers of the United Kingdom, New Zealand and South Africa.

A message from H.M. The Queen, who has announced her intention of conferring a knighthood upon Dr. Fuchs, said: "On the completion of your hard and adventurous journey across Antarctica my husband and I send our warmest congratulations to you and all members of the Commonwealth Trans-antarctic Expedition. You have made a notable contribution to scientific knowledge and have succeeded in a great enterprise. Well done. Elizabeth R."

Woods Hole Oceanographic Institution:

Dr. C. O'D. Iselin

DR. C. O'D. ISELIN, director of the Woods Hole Oceanographic Institution and its mainstay since it was founded in 1930, is retiring. He started his oceanographic career by exploring the Labrador current in his own schooner *Chance* in the summer of 1926. He had much to do with the building of *Atlantis*, which still serves the Institution, and took command on her first voyage in 1931. He was appointed director of the Institution in 1940, but after serving for ten years asked to be relieved of this responsibility (as Dr. Bigelow had done after the first ten years) to gain time for research. He is best known for his contributions to our knowledge of the Gulf Stream and the circulation of the western North Atlantic Ocean, but since 1940 he has devoted much of his time to the commendable task of guiding the many new developments created by the growing demands of science, defence and industry, for better understanding of the oceans. Although it has been a period of great expansion of interest in marine physics, he has maintained the traditional interest of the Woods Hole Institution in biological problems, and has done much for the local fisheries. For his work on the application of science to undersea warfare he was awarded the Legion of Merit in 1948, and he received the Agassiz Medal of the U.S. National Academy of Sciences in 1951. He had to return to the directorship of the Institution as a temporary measure in 1956 on the retirement of Admiral E. H. Smith, and will continue to be associated with the laboratory as the first holder of the chair of Henry Byant Bigelow Oceanographer recently founded by the Board of Trustees.

Dr. P. M. Fye

DR. PAUL M. FYE, the future director, is a chemist with long experience of government service and research administration. In 1942, at the age of thirty, he went to the Underwater Explosives Laboratory at the Woods Hole Institution, and became research director of the project in 1945. After the Second World War he returned to teaching for a year in the University of Tennessee, and then went to work at the Naval Ordnance Laboratory, where he was appointed associate director for research in 1956. His research interests have been in the fields of gas kinetics, photochemistry, purification of gases, high explosives damage, underwater photography, gas equilibria, liquid state and explosion of products. His work at Woods Hole and in the Naval Ordnance Laboratory has interested him in oceanographic problems, and he is well known to marine scientists in the United States.

Mathematics at Bedford College :

Prof. W. N. Bailey

The retirement of Prof. W. N. Bailey from the chair of mathematics at Bedford College, in the University of London, has been announced. Previous to his appointment to this chair in 1944, Prof. Bailey had been for many years senior lecturer in mathematics in the University of Manchester. He is best known for his work on generalized hypergeometric series, being the author of a number of papers on the subject, and of a Cambridge Tract (published in 1935) which is the standard work of reference. He is a D.Sc. of the University of Manchester and an Sc.D. of the University of Cambridge. He has held several offices in the London Mathematical Society, having been librarian during 1944–46, editor of the *Proceedings* during 1946–49, secretary 1954–55 and vice-president during 1955–57.

Dr. H. G. Eggleston

Dr. H. G. Eggleston has been appointed to the chair of mathematics at Bedford College in the University of London, in succession to Prof. W. N. Bailey. Dr. Eggleston has been lecturer in mathematics in the University of Cambridge since 1953, having previously held an appointment at University College, Swansea. He is one of the younger generation of analysts who have established their reputation since the Second World War : he graduated at Cambridge in 1943, took the Ph.D. degree in 1948 and was awarded an Sc.D. in 1954. His work has been mainly in real variable theory, particularly the theory of measure and the properties of convex sets. His distinguished contributions to these fields have been recognized by the award to him, last year, of the Adams Prize in the University of Cambridge. He is at present a member of the editorial committee of the Cambridge Philosophical Society, and a member of the Council of the London Mathematical Society.

Physiological Chemistry in the University of Reading

The Department of Agricultural Chemistry in the Faculty of Agriculture and Horticulture of the University of Reading is concerned with animal nutrition, soil science, dairy chemistry and pesticide chemistry. Modern developments in these subjects have been particularly concerned with physiology and biochemistry, which have accordingly in the past few years figured prominently in the Department's teaching and research programme. These developments, and the fact that there is no separate department in the Faculty of Science concerned with physiology or biochemistry, have resulted in the establishment of the Department of Physiological Chemistry. It will be formed in October 1958, and will have responsibilities to both Faculties. In the Faculty of Agriculture and Horticulture, teaching of, and research in, the various branches of agricultural chemistry will continue as before. This teaching consists of the provision of the honours degree course in agricultural chemistry and of what may be called 'service courses' for students reading for degrees in agriculture, horticulture, dairying and agricultural botany. In the Faculty of Science there will ultimately be courses in physiological chemistry to general and special degree levels, but these developments will depend upon the provision of more laboratory space and the recruitment of new staff. Prof. C. Tyler, who has been professor of agricultural chemistry since 1947, will become professor of physiological chemistry on September 30, and the staff of the Department of Agricultural Chemistry will form the nucleus of the staff for the new department.

European Organization for Nuclear Research

Replying to a question on February 25 regarding the laboratories of the European Organization for Nuclear Research at Geneva, Mr. H. Nicholls, Parliamentary Secretary to the Ministry of Works, as representing the Lord President of the Council, said that the smaller nuclear particle accelerator has undergone running trials and is now available for full-scale research. The larger accelerator should come into service in 1960, and good progress is also being made with the laboratory buildings. The third annual report of the Organization will be issued shortly. The United Kingdom has provided about 40 of the total staff of 170 and is responsible for about a quarter of the total cost of the project of £15 million.

Preservation of Hadrian's Wall

The methods used in preserving Hadrian's Wall were discussed in the House of Commons on February 25. The Minister of Works, Mr. H. Molson, said in reply to a question that the methods of maintenance used by the Ministry have been approved by the Ancient Monuments Board for England. The archæological policy in carrying out the repair work is directed by the Ministry's Inspector of Ancient Monuments, who has visited the work periodically and has had the co-operation of local archæologists who are specialists on Hadrian's Wall. The day-to-day work is supervised by staff with long experience of archæological restoration. Original Roman work is exposed, retained and consolidated in the state in which it is found. Fallen stones are replaced if their original position is known, and stones on the point of falling are removed from the Wall and re-bedded. Apart from this re-bedding, there has been no dismantling of the Wall at Birdeswald or elsewhere. Roman mortar is kept wherever possible, and on exposed surfaces lime mortar is used when necessary. Mr. Molson said that he has had letters from Prof. E. Birley and Mr. J. P. Gillam, professor and reader, respectively, of Romano-British history and archæology in the University of Durham, approving of what had been done.

Ordnance Survey

In replying for the Government in an adjournment debate on February 20 on redundancies in the Ordnance Survey Department, Mr. J. B. Godber said that the Ordnance Survey had for some years been endeavouring to recruit cartographic draughtsmen and surveyors through the Civil Service Commission, but had not succeeded in filling its authorized non-industrial complement. Last summer there was a marked improvement in recruitment and more than 200 out of nearly 300 candidates were accepted. Continuance of recruitment at this rate for two or three months would have filled the authorized complement, and sufficient established recruits would have been available to replace the temporary staff during 1958. Meanwhile, the Civil Service Arbitration Tribunal awarded an increase of about 15 per cent in the rates of pay for cartographic draughtsmen, and in consequence of the Government's policy that increased wages costs falling on the Exchequer should be met by corresponding savings elsewhere, it was decided to restrict the Ordnance Survey

Department's non-industrial strength to 3,827. In consequence, the Department had 200 fewer posts and more than 200 additional draughtsmen, 50 of whom had been asked to report for duty. After considering the three alternative possibilities, the Minister decided, in view of the adverse effect on recruitment of the alternatives, the importance of a proper age distribution and of the maximum proportion of permanent staff, to advance the anticipated discharge of temporary staff during 1958, most of whom were eligible for consideration for a gratuity, and discharge some temporary staff immediately and the remainder over a period of nearly a year, not more than twenty-five in any three months. Mr. Godber emphasized that most of them had had an opportunity to become established at some time.

Agricultural Research

Mr. J. B. Godber, Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food, in a written answer for the Lord President of the Council in the House of Commons on February 17, gave the total estimated expenditure on agricultural research co-ordinated by the Agricultural Research Council for the present financial year as £4,657,000, of which £2,033,000 is for animal research, £2,084,000 on plants and soils research and £350,000 on research on agricultural machinery. Research under the Ministry of Agriculture, Fisheries and Food was estimated to amount to another £166,000 on animal research and £2,000 on plant research.

University Apartheid

As a result of suggestions made by participants at the meeting on university apartheid held in London in November (see *Nature*, **180**, 1163; 1957), the International Committee on Science and Freedom, in co-operation with the World University Service, has launched an appeal for funds to help non-white South African students to obtain university education at one of the two 'open' universities, at Cape Town and Witwatersrand, before the Separate University Education Bill, reserving these universities for whites only, becomes effective in South Africa. This legislation will probably not become effective before January 1959; students who are attending a university at that time will be allowed to finish their course. If and when the Separate University Education Bill becomes effective, then the funds collected in aid of non-white students will be used to help them to attend universities outside South Africa. The World University Service will distribute the money, in the first instance, among the organizations that have been formed in South Africa, under university auspices, to assist non-white students to obtain university education. These organizations will be responsible for selecting the students who are to benefit from financial aid, and watching over their progress. Contributions to this fund can be sent to the Secretary, World University Service, 59 Gloucester Place, London, W.1, from whom further information can be obtained.

Importation into Britain of Liquid Natural Gas

A development of singular interest has recently been reported, namely, the importation into Britain of liquefied natural gas, to be used in the gas industry. There are many parts of the world in which natural gas is found, but in which there is no local demand for fuel. If the importation of such gas from such sources can supplement the fuel supplies of industrial areas on an economical basis, then the development constitutes an addition to the utilizable fuel supplies of the world. Trial shipments of natural gas, liquefied by the use of an already existing liquefaction plant constructed on a barge, are to be taken from the Gulf Coast oilfields to a depot on Canvey Island. The technical problem which appears to have been overcome is the construction of insulated tanks, and the ballasting of the ship to carry the exceptionally light cargo. It is well known that normal materials for the construction of such tanks are liable to lose the required properties at the very low temperatures involved, in this case − 260° F., for liquefaction at atmospheric pressure. A new transmission line is being laid from Canvey Island to connect with a high-pressure main already in existence between Shellhaven and Romford Works, and the gaseous methane will mix with refinery gases from the Shellhaven refinery. The vessel which is being converted for a trial load is a double-bottom cargo ship about 340 ft. in length which, after conversion, will carry about 2,000 tons of liquid methane. The methane, of which natural gas mainly consists, and a rich gas of a calorific value of 1,000 B.T.U. per cu. ft., will be transformed into gas of the normal towns' gas value of 500 B.T.U. per cu. ft. for use in consumers' appliances. The results of this venture will doubtless be watched with great interest.

Aerodynamics

A symposium on "Real Gas Effects in High Speed Flow" held at the Armament Research and Development Establishment, Fort Halstead, on February 11, was attended by representatives of the Government research establishments, the universities and interested firms. Four papers were presented, the first by K. N. C. Bray (University of Southampton) discussing "Relaxation Phenomena in a Hypersonic Nozzle". Using Prof. Lighthill's model of an ideal dissociating gas and Dr. Freeman's equation for the rate of dissociation, Bray showed that for a typical hypersonic nozzle it is unlikely that the flow would reach thermodynamic equilibrium and that the nozzle exit, that is, test conditions, would be unrepresentative of free flight. These very interesting conclusions are in direct contrast to other previous work. In "The Effect of Relaxation on Gas Properties", D. H. G. Frood (University of Liverpool) examined the flow chemistry behind a strong shock and suggested that dissociation need not occur from the ground-state only, as postulated by previous workers. This would explain the short dissociation relaxation times found experimentally. B. G. Woods (Royal Aircraft Establishment, Farnborough) presented the results of some shock-tube performance calculations in his paper "Real Gas Effects in the Hypersonic Shock Tube". He directed attention to the difficulty of avoiding slip-flow test conditions when expanding to flow temperatures representative of the atmosphere. Real gas effects reduce to less than half the testing period at shock strengths greater than 10. The final paper, on "Energy Transfer through a Dissociated Gas in Couette Flow", was read by J. F. Clarke (College of Aeronautics, Cranfield). The chemical composition of the flow was presented, together with the velocity and temperature profiles for both chemically frozen flow and flow in thermodynamic equilibrium. The heat-transfer and skin-friction relations were also described. The meeting ended with a brief tour of the hypersonic test facilities at Fort Halstead. Fuller reports of the papers presented and the discussion are to be published by the Establishment.

British Group for Engineering Applications of Automation

The British Conference on Automation and Computation is being organized in three sections, as follows: (*A*) the British Group for the Engineering Applications of Automation; (*B*) the British Group for Computation and Automatic Control; and (*C*) the British Group for the Sociological and Economic Aspects of Automation Techniques (*Nature*, 179, 948; 1957). The British Group for Computation and Automatic Control, Group *B*, was formally constituted on December 20 (*Nature*, 181, 237; 1958). At a meeting held on February 20, Group *A*, the British Group for the Engineering Applications of Automation, was formally constituted, comprising as its members twenty-one professional and learned institutes and societies with interests in this field. The objects of the Group are: to foster the development of the engineering applications of automation; to afford a common meeting ground for the adhering organizations; to maintain liaison with other Groups of the British Conference on Automation and Computation and with corresponding national committees of other countries; and to encourage and to coordinate the presentation at international conferences of British papers on subjects falling within the purview of the Group. Dr. D. F. Galloway, a member of the Council of the Institution of Mechanical Engineers, was elected chairman of the Group, with Mr. J. S. Brough and Sir Walter Puckey (past-president of the Institution of Production Engineers) as vice-chairmen. Mr. Brian G. Robbins (secretary of the Institution of Mechanical Engineers) was elected honorary secretary, and the offer of the Institution of Mechanical Engineers to provide secretarial services for the Group was accepted. Dr. Galloway, Mr. Brough and Sir Walter Puckey will represent Group *A* on the general committee of the British Conference on Automation and Computation, which is made up of three representatives of each Group. The constitution of the Group provides for the election of additional member societies: those interested should write to the honorary secretary of the Group, at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

Foundation of an Association of Radiobiologists

The formation of an Association of Radiobiologists has been under consideration for some time (*Nature*, 180, 411; 1957). At a recent meeting of the Radiation Research Visiting Club, a steering committee was set up to propose the constitution of some form of association which would not jeopardize the future of the Club as it is at the moment. The Radiation Research Visiting Club has been invited to visit the Experimental Radiopathology Research Unit, at Hammersmith Hospital, on May 9 and 10, and an open meeting is to be held on May 9 at 5 p.m., at which the steering committee will formally propose the formation of an Association. The question as to whether an Association should be formed and, if so, the general nature of its constitution, will be debated. If it accords with the wishes of the meeting, an Association will come into being at this meeting and a body of persons will be elected to draw up rules and to attend to any other business of the Association which the meeting shall direct. Any interested person who wishes to attend this meeting, and who has not previously been in contact with the Radiation Research Visiting Club, should communicate with the Director, Experimental Radiopathology Research Unit, Hammersmith Hospital, Ducane Road, London, W.12.

Trace Metals and Nitrogen Metabolism

In an investigation of the function of trace metals in the nitrogen metabolism of plants, D. J. D. Nicholas (*Annals of Bot.*, N.S., 21, 587; 1957) has pointed out that trace metals have been found to be associated with flavoproteins, a number of which are key enzymes in the nitrogen metabolism of plants. Thus, molybdenum is a constituent of nitrate reductase which catalyses the reduction of nitrate to nitrite in some bacteria, fungi and higher plants. During the enzymic reduction of nitrate a one-electron change is involved, $Mo^{6+} \rightleftharpoons Mo^{5+}$. Nitrite and hyponitrite reductases both require iron and copper and flavin for maximum activity and are inhibited by uncoupling reagents so that a phosphorylation takes place at these two reductive steps. Hydroxylamine reductase is a flavoprotein dependent on manganese, but, as with nitrate reductase, it is unaffected by uncoupling reagents. An aromatic route may also exist in plants for the reduction of organo-nitro compounds, but it is more likely that the aliphatic route is the primary reductive pathway.

Molybdenum, vanadium, tungsten and iron may all be involved in the process of nitrogen fixation in free-living micro-organisms and in the root-nodule bacteria. The suggestion that the enzyme hydrogenase is coupled to nitrogen fixation is not borne out by the results of valency experiments with molybdenum and vanadium, which show that an active hydrogenase does not necessarily result in a vigorous fixation process. Although molybdenum has been shown to be a constituent of hydrogenase from *Clostridium pasteurianum*, experiments in the Long Ashton Research Station laboratory show that a deficiency of iron only reduced the enzyme in this organism and in *Azotobacter*. Both molybdenum and iron, however, are essential for nitrogen fixation. In some strains of *Azotobacter*, vanadium or tungsten can partially replace molybdenum for nitrogen fixation.

The Folklore of Birds

A survey of English folklore is being made by the Department of English in University College, London, under the guidance of Prof. A. H. Smith, with the assistance of Mr. J. McN. Dogson. The object of this survey is to collect an archive of folklore materials rather than to prepare, in the early stages at least, studies and monographs on particular aspects of folklore. A large and representative body of voluntary collectors and informants from all parts of the country is needed, and those who are interested should write for information to the English Folklore Survey, University College, Gower Street, London, W.C.1. Questionnaire No. 8 of the English Folklore Survey deals with birds. It seeks information on the popular lore relating to birds, on popular beliefs about the physical appearance, habits and life-cycles of British birds, both wild and domestic, on any association of birds with good or ill luck, or with weather, etc. Informants are requested to send in information referring to various aspects of bird-life in folklore discussed under fourteen headings. British ornithologists and especially bird watchers should be interested in the work carried on by the survey.

Radiofrequency Spectroscopy Group

A discussion will be held on "High Resolution Nuclear Magnetic Resonance" in Oxford during April 21–22, organized by Dr. R. Richards. Limited accommodation will be available in college for those who wish it. Reservation forms for this should be obtained from Dr. R. Richards, Lincoln College, Oxford. It is hoped that there will be contributions on the theory of high-resolution spectra, its application to organic and inorganic chemistry, and on the design of spectrometers. It is not intended to have any introductory accounts of the subject. Another meeting will be held during September 22–23, at Newcastle, on "Magnetic Resonance in the Solid State", organized by Dr. E. E. Schneider. Further information about these meetings and the Group can be obtained from Dr. D. J. E. Ingram, Honorary Secretary, Radiofrequency Spectroscopy Group, The University, Southampton.

Physical Society Exhibition

The Physical Society's annual Exhibition of Scientific Instruments and Apparatus will be held in the Old and New Halls of the Royal Horticultural Society, Westminster, S.W.1, on the following dates: March 24, 10.30 a.m.–7 p.m. (Fellows and Press only, 10.30 a.m.–2 p.m.); March 25, 10 a.m.–9 p.m.; March 26, 10 a.m.–7 p.m.; March 27, 10 a.m.–4.30 p.m. The size of the Exhibition is expected to be similar to that of previous years, including 133 exhibitors, and a large number of universities, hospital physics departments and research organizations are again participating, thus assuring a high proportion of purely research exhibits. The following discourses, to be delivered at 5.45 p.m. on the dates indicated, are to be given: March 24, "Goethe's Colour Experiments", by Mr. M. H. Wilson (Goethean Science Foundation); March 25, "Some Uses of Physics in Archæology", by Dr. E. T. Hall (Research Laboratory for Archæology and History of Art, Oxford); March 26, "Some Recent Investigations with Aircraft on the Physics of Clouds and Rain", by Mr. R. J. Murgatroyd. As in previous years, the Society is publishing a "Handbook of Scientific Instruments and Apparatus" in connexion with the Exhibition (6*s.* net or 7*s.* 8*d.* post paid). All inquiries should be addressed to the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

University News:

University College of Rhodesia and Nyasaland

Lever Brothers (Rhodesia), Ltd., has given £10,000 to the University College of Rhodesia and Nyasaland to endow a Research Fellowship. The Lever Research Fellowship will be of the value of £650 per annum, and preference in its award will be given to male graduates who wish to pursue advanced study and research in chemistry, chemical engineering or allied subjects. There are no restrictions of race or colour for candidates, who must normally be residents or children of residents in the Federation of Rhodesia and Nyasaland.

Sheffield

The following have resigned: Prof. R. P. Jepson, on his appointment as professor of surgery in the University of Adelaide; Prof. W. Hobson, on his appointment as medical officer in training and education in the World Health Organization Regional Office, Copenhagen.

The University has received the following grants: £2,000 a year for the next five years from the Town Trustees. This will be used for strengthening the recently created Department of Psychiatry. 8,500 dollars from the Rockefeller Foundation for research in microbiology.

Announcements

The following awards have been announced by the Royal Society of Edinburgh: Keith Prize, 1955–57, to Dr. I. M. H. Etherington, for his papers on algebra published in the *Proceedings* of the Society during the period of the award and for his earlier contributions in the same field; Neill Prize, 1955–57, to Monica Taylor, for her joint paper published in the *Proceedings* of the Society during the period of the award and in recognition of her distinguished contributions to protozoology.

Dr. D. G. Evans has been appointed director of the Division of Biological Standards at the National Institute for Medical Research in succession to Dr. W. L. M. Perry, who is going to the chair of materia medica in the University of Edinburgh.

The annual open day of the Glasshouse Crops Research Institute will be held on June 11. Further information can be obtained from the Institute, Worthing Road, Rustington, Littlehampton, Sussex.

The 1958 annual conference of the Textile Institute will be held at Edinburgh during May 12–16. The subject will be "Fibre Blends and Mixtures". Further information can be obtained from the Textile Institute, 10 Blackfriars Street, Manchester 3.

A general discussion, organized by the Faraday Society, on "Configurations and Interactions of Macromolecules and Liquid Crystals" will be held in the Department of Chemistry, University of Leeds, during April 15–17. Further information can be obtained from the Secretary, Faraday Society, 6 Gray's Inn Square, Gray's Inn, London, W.C.1.

The Institution of Electrical Engineers is holding an International Convention on Microwave Valves during May 19–23. Further information can be obtained from The Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

The third congress of the International Federation of Prestressing will be held in Berlin during May 5–10. Further information can be obtained from Mr. Philip Gooding, Secretary, Prestressed Concrete Development Group, Terminal House, Grosvenor Gardens, London, S.W.1.

The eighth annual meeting of the Société de Chimie Physique, which is to be held in Paris during May 27–30, will be devoted to a discussion on "Transferts d'Energie Lumineuse et Photosensibilisation". Further information can be obtained from Prof. G. Emschwiller, Ecole Supérieure de Physique et de Chimie, 10 rue Vauquelin, Paris Ve.

Erratum. In the communication entitled "*Iso*leucine and Allo-*iso*leucine" by Anna W. I. van Dam-Bakker in *Nature* of January 11, in line 8 on p. 117, the comment "erroneously called threonine by Shulgin" is incorrect; the phrase should read "an allo-configuration is also possible for hydroxyproline, hydroxylysine and threonine, which also contain 2 asymmetric carbon atoms".

INDUSTRIAL CARBON AND GRAPHITE

THE rapidly developing interest in carbon and graphite was demonstrated by the presentation of more than sixty papers, running in preprint form to more than 500 pages, to the Conference on Industrial Carbon and Graphite organized by the Society of Chemical Industry and held in London during September 24–26. In part, the enhanced importance of these materials has arisen from the employment of graphite as a moderator in nuclear-power production, but the use of industrial carbon in many other branches of industry has also increased greatly in the past two decades.

The Conference was opened by Dr. H. K. Cameron, who surveyed the traditional uses of carbon, and modern developments from them, and ventured to predict some of the problems of carbon technology which might be solved in the future.

Historically, the expanding industrial use of carbon has depended mainly upon the evolution of a technology for the conversion of the irregular piece of coke or char resulting from the carbonization of organic matter into strong, rigid, macroscopically homogeneous forms suitable for industrial application. The basic process has remained unchanged for a century. The primary coke is ground (to form the 'grist'), mixed with a suitable binder (such as tar or pitch), pressed or extruded into the desired shape and calcined. The binder decomposes to form a secondary coke which links together the particles of the primary coke to produce a rigid product. At this stage the material is called 'industrial carbon'. In recent years a further process is often added in which the carbon is heated in an inert atmosphere (such as argon) to temperatures in excess of 2,000° C. to induce graphitization. The product is 'industrial graphite'.

Materials prepared in this way find many applications. Among those dealt with specifically at the Conference were: as electrodes in both electrochemical furnaces (used, for example, in aluminium production) and in melting furnaces; as moulds, crucibles and dies in metallurgical processes; in the construction of chemical plant to withstand either high temperatures or corrosive conditions; as carbon brushes for electrical machines; as dry bearings; as electrical resistors both in the electronics industry and in heavier electrical applications; and finally as a moderator in nuclear piles.

Industrial carbon and graphite differ from natural graphite in many important respects, most of which were referred to during the Conference. These differences are structural rather than chemical in origin, and are associated with features ranging from variations in the crystal lattice of sub-microscopic regions of the material, to heterogeneity on the microscopic and occasionally on the macroscopic scale which results inevitably from the method of manufacture. The properties of the final product depend on many factors, including the nature of the basic raw material, the way in which it is carbonized, the method of grinding, the size distribution and the shape of the grist particles, the nature of the binding agent and the amount used, the method of forming the product (pressing or extrusion), the conditions of the second carbonization and finally the temperature of graphitization and the atmosphere in which it is carried out. These factors often interact with one another, so that the problem of understanding the nature and properties of a given industrial carbon or graphite in relation to its method of preparation is exceedingly complex, and in the absence of a fundamental understanding, a substantial body of empirical technique has been built up in the industry. The papers presented to the Conference show, however, that real attempts are being made to rationalize knowledge of the fundamental processes, and to relate this knowledge to the properties of the final product by the correlation of information derived from a wide range of experimental methods.

The property which reflects most directly the difference between artificial carbons and natural graphite is the bulk density: industrial materials rarely exceed a density of 1·75 gm./cm.^{3}, whereas graphite has a density of 2·26 gm./cm.^{3}. This difference arises from structural differences at all size-levels. It is generally presumed (although not definitely proved in all cases) that the basic structural unit of carbonized materials is the C_6-ring, although the presence of some side-chains with free valencies is also assumed. Evidence for the presence of free radicals comes from electron-resonance studies (Ingram). These rings are fused together to form planar aggregates which may be complete or possess 'holes' of various kinds. X-ray studies show that natural graphite consists of perfect planes of fused rings, arranged parallel to one another with a definite interlayer spacing, and with the orientation of each plane relative to its neighbour completely defined. The energies of the electronic configurations in the graphite structure are not yet calculable with high accuracy, and an attempt to obtain evidence about them by studying the reflectance of light of various wave-lengths by polished graphites was reported to the present Conference by Humphreys-Owen and Gilbert. Less-perfect structures of lower density occur when the relative orientation of the rings in adjacent planes is random, and the average distance between planes increases slightly: the structure is said to be 'turbostratic'. Amorphous carbons have also been subjected to careful study by X-ray techniques, and it is concluded that they consist of graphite-like crystallites, the size of which may range from the order of ten angstrom units to several hundred, interspersed with turbostratic and possibly even more randomly arranged carbon. In addition, nearly all carbons have a characteristic porous structure consisting of cavities the dimensions of which may range from a few angstroms to tenths of a millimetre, and the shapes of which may vary widely. Each individual carbonized material has its own characteristic structure, while the industrial carbons under discussion consist of an intimate blending of two such structures, one arising from the primary coke and the other from decomposition of the binder. Some of the more important implications of this two-component structure were brought out in Mrozowski's general introduction to the Conference, which stressed not only the complexities of the microstructure of artificial carbons, but also the analogy between them and compressed powders.

X-ray studies have formed the basis of many of the conclusions regarding the molecular structure of carbon and graphite, and a survey of diffraction methods (including neutron diffraction) was given by Bacon, while a rapid X-ray method for determining the preferred crystallographic orientation was described by Ali, Fitzer and Ragoss. Recent work on the structure of carbonized coals was reported by Diamond and Hirsch, while the carbonization products of materials of known composition have been examined by Stadler and Thomson (single crystals of flavanthrone) and by Winslow, Matreyek and Yager (vinyl polymers). Further work on the progress of graphitization at high temperatures, as revealed by X-ray studies, was reported by Maire and Mering, and by Steward and H. W. Davidson. Correlation is found by Adamson and Blayden between the size of the graphite crystals and the magnetic susceptibility, and these authors used the latter property to study the dependence of crystallite size on starting material and thermal treatment. Other properties which are closely related to the structure of carbons are the thermal and electrical conductivities. They depend mainly on the size, orientation and density of the crystallites, but in different ways in various ranges of temperature. Consequently, measurements of thermal and electrical conductivity over a wide temperature-range are important (Berman; Powell; Albert and Parisot; Mason), especially when associated with X-ray studies (Bowman, Krumhansl and Meers). The porosity of carbons is a property which in some applications is desirable and for many others undesirable. Reliable methods for assessing the total porosity and its distribution in terms of the size of cavities are therefore important. Bond and Spencer reviewed methods developed at the British Coal Utilization Research Association for studying the ultra-fine structure of coals and carbonized coals, while Academician Dubinin surveyed Russian work on the correlation of adsorptive properties with porous structure. A paper by Cadenhead and Everett was concerned with the elucidation of the porous structure of carbons by a study of the thermodynamics of adsorption processes. Gas permeability methods are widely used for assessing porosity, although the fundamental theory of the method is far from satisfactory. Papers by Wiggs and by Hutcheon, Longstaff and Warner discussed both the theory and the interpretation of experimental results on industrial graphites.

The major part of the porosity of an industrial carbon is associated with the secondary coke formed by decomposition of the binder. Consequently, it is desirable to use the minimum amount of binder. The grist aggregate must therefore have a minimum of inter-particle voids, and optimum packing is achieved by blending different particle sizes in the grist. The shape as well as the size of grist particles is also important, and this has been studied by Amstein and Watson. Furthermore, extruded carbons are anisotropic and this is in part controlled by the particle shape (Grossman). The choice of suitable binder is of great importance, and several papers (Darney; McNeil and Wood; Blakeley and Earp; Lessing) were devoted to this problem. A systematic investigation of the variation of the properties of carbons, in particular mechanical strength and electrical resistivity, with amount of binder and with the composition of the grist, was reported by Fialkov.

The manufacture of electrodes having long life is important economically, both in the production of aluminium and in electro-melting: half a ton of carbon is consumed for each ton of aluminium produced, while 15 per cent of the cost of converting scrap steel to ingots arises from electrode wear. Two problems in the production of electrodes for aluminium cells were discussed. The first is concerned with the cracking of electrodes during baking, which causes uneven current distribution. According to Pratt, this arises from shrinkage of the grist during the second carbonization, and he has studied the shrinkage of cokes at 1,000° C.; this is shown to be related to the hydrogen content of the coke. Disintegration of the electrode surface, arising from preferential oxidation of one component of the carbon, also makes an important contribution to electrode wear, and Bowitz, Böckman, Jahr and Sandberg attribute this to the greater porosity and reactivity of the coked binder. The mechanism of electrode consumption in melting furnaces is not clearly understood, and the work of Ravenscroft and Preston on the distribution of electrode wear at different points on the surface as a function of electrode current and voltage provides some basic information about the phenomenon.

Problems of electrode life, as well as many industrial applications of carbon, depend upon the reactivity of carbons towards oxidizing gases. A fundamental study by J. D. Watt and Franklin in which changes of structure arising from oxidation were studied by X-ray methods suggests that the most reactive part of a porous carbon structure consists of single, unstacked, graphite layers which can adsorb oxygen on both faces. The kinetics of reaction of carbon with various gases continues to be studied, and a number of recent researches were reported (Graham, A. R. G. Brown, Hall and W. Watt; Earp and Hill; Walker and Nichols; Day, Walker and Wright); particular emphasis is now being placed on measurements at high temperatures (1,500–2,500° C.) and at high rates of gas flow. The effect of surface oxides on the reactivity of carbon was the subject of a paper by Harker, Marsh and Wynne-Jones.

In the electrical industry great importance is attached both to the electrical conductivity of carbon, and to the contact resistance at carbon–carbon and carbon–metal interfaces. A review of developments in applications of carbon to current-collection was given by Vaughan, with particular reference to behaviour under high-altitude conditions, where, in the absence of water vapour, the friction between brush and metal commutator increases and rapid wear ensues. Experimental studies of the electrical properties of sliding contacts at low gas-pressures were described by Millet. In these applications metallized types of graphite are often employed, and details of the production of copper–graphite materials were given by Beech and Price. The contact resistance at carbon–carbon surfaces, and its dependence on load, is important both in high-duty variable carbon-plate resistances and in carbon microphones. The former application was discussed by Knowles, while measurements of the electrical characteristics of microphone carbon as a function of frequency were reported by Fairweather, Frost and Shirley. Blanchard presented results on the electrical conductivity characteristics of a wide range of compressed carbon blacks, in particular in relation to their dependence on heat treatment, while Dawson and White reported on the properties of resistors made from various carbon blacks bonded with resins.

Methods of preparing dense, unreactive carbon are of great importance. If successful, they would find application both in bulk form and as surface coatings for less dense material. Recent work (A. R. G. Brown and W. Watt) shows that dense impervious material is produced by the thermal decomposition of hydrocarbons at a hot surface (1,600–2,100° C.), and surface coatings of this kind enhance the chemical resistance of more reactive graphites. The kinetics of deposition of carbon films from benzene and toluene vapour carried by a stream of helium in a rather lower temperature range (850–950° C.) have been studied by Kinney and Murphy.

Carbons as normally prepared may contain, besides small amounts of trace elements, a substantial amount of hydrogen, oxygen, nitrogen and sulphur. These elements may have an important influence on the structure, and Riley, Baraniecki and Streeter reviewed the properties of these 'heterocarbons'. The particular case of graphitic oxide has been studied extensively in the past thirty years: the present position was reviewed by de Boer and van Doorn in the light of their more recent work.

Considerable emphasis was placed on industrial carbon as a constructional material. Reviews of its applications in various industries were contributed by Lyddon and Hurden (mechanical engineering); K. F. Anderson (chemical engineering); H. D. Anderson and Ward (chemical plant); Hilliard (heat exchangers); Haines (high-temperature furnaces); G. E. Ross and D. W. Brown (metallurgy); Lakin and Mackenzie (blast-furnace linings). The mechanical properties relevant to these applications were discussed by H. W. Davidson, Losty and A. M. Ross, and by Arragon and Berthier, while methods of non-destructive testing were outlined by T. D. Davidson.

The most important new field of application of industrial graphite is in nuclear-power plant, where to the desirable properties of high density, low reactivity and mechanical strength, must be added the over-riding requirement of high purity. Discussions of this application and of the required properties were contributed by McIntosh, Heal and Cowan; Lockett; and McIntosh, O'Driscoll and Tyzack. Special attention has to be paid to the effects of high temperatures and of neutron irradiation, and papers by Hove and by Simmons were concerned with these problems. In studying the suitability of various raw materials and manufacturing procedures for nuclear-graphite production, large-scale experimental plant is needed, and that recently constructed at Harwell was described by Price and Yeats. The problems arising in the manufacture of nuclear graphite were discussed by Cornault and Rochettes. High purity may in principle be attained either by using very pure raw materials, by the purification of ordinary graphite or by purification in the course of the final graphitization. The latter method is that actually chosen, and a study of the purification of graphite by treatment with gaseous chlorine or a chlorofluorohydrocarbon during graphitization was the subject of a paper by Odening and Bowman. The resultant purity depends on the permeability of the carbon: the high density and low porosity desirable in graphite for use as a moderator may not be compatible with gas-purification methods. Methods of estimating the purity of reactor graphite were mentioned in several papers—the usual method being to compare the effect of different graphites on the time required for the reactor to become critical; detection and estimation of rare earths by the radioactivation technique and a study of the changes of rare earth content in the course of graphite manufacture was described by Decour, Leveque, Hering and Jouquet. The alteration of properties brought about by purification was discussed by Baroin.

During the period of the Conference an exhibition of industrial carbon and graphite was held in the Department of Chemical Engineering, University College, London; and this, together with several social functions, contributed to the success of the Conference.

D. H. EVERETT

SAFETY IN MINES RESEARCH

THE scope of the Safety in Mines Research Advisory Board was widened early in 1956 when the Board was re-appointed, with Prof. R. V. Jones as chairman, and given new terms of reference which ask the Board "to keep under review and advise the Minister of Power on the general scope, organization and progress of research work on safety in mines". Until then the scope had been restricted to the Ministry's research work on the subject. It is appropriate, therefore, for the thirty-fifth annual report on safety in mines research (London: H.M. Stationery Office, 1958) to include a short account of the ninth international conference of directors of safety in mines research and to give in appendixes not only synopses of recent publications of the Safety in Mines Research Establishment, but also a list of papers presented by all the delegates to the ninth international conference.

The report, however, is essentially a report of the work of the Safety in Mines Research Establishment for the year 1956. During the year the move to new premises, in Broad Street, Sheffield, housing the engineering sections and much of the Technical Information Service Department, was begun. It is significant that the acute problem of accommodation has resulted "as much from increasing the strength of research teams to the necessary extent, as from the increasing complexity of the work". As the director of the Establishment, Mr. H. T. Ramsay, remarks in his introduction to the report, "Mining research has been in progress for a long time and the easier answers have usually been found; real advances against the remaining hazards will only be made by a penetrating study of their mechanisms and, so far from becoming easier, one may expect the Establishment's work to become more difficult".

Most of the report is concerned with the research of the Establishment into the hazards of mining. There are eight main sections, namely, explosives and blasting devices, the explosion hazard, breathing apparatus, fire hazard, engineering and metallurgical research, dust control and pneumoconiosis hazard, miscellaneous, and testing services. The wide scope of the work of the establishment is illustrated by the fact that within the eight main sections there are nearly a hundred sub-sections dealing with such widely different topics as pulsed infusion of coal, ignition of gases by sparks of various origins, fighting roadway fires with foam-plugs, atomic hydrogen welding of wrought iron, catalytic oxidation of exhaust gases of Diesel locomotives, deposition and dispersion of respirable dust, automatic assessment of miners' pneumoconiosis from chest radiographs, safety helmets and factors affecting the movement and control of rats in drift mines.

It is not easy to select from the necessarily highly condensed accounts of investigations included in the report examples which illustrate adequately the scope and quality of the work of the Establishment; accordingly, the largest sections, those devoted to the explosion hazard and to engineering and metallurgical research, are selected for mention. The report points out that, during the decade 1946–55, there was a marked decrease in the number of casualties from explosions in mines in Great Britain, due not to any great reduction in the number of gas ignitions but to reduced severity of the explosions as measured by the number of casualties. This improvement may well be due to improved mine ventilation and gas control, with consequent reduction in the size of accumulations of gas available for inflammation. It is felt by the Establishment that current research on the causes of ignition of gas in mines should be supplemented by research on the movement of firedamp in mines and on the dispersal of accumulations of gas. Coal-dust explosions in mines are generally initiated by explosions of methane, so that attention continues to be directed towards the ignition of methane, particularly by frictional sparking such as may occur when certain light alloys strike rusty steel, or from steel chock releases, or from auger mining, or from rocks during drilling.

So far as coal-dust explosions are concerned, the report includes work on binding of coal dust by dilute solutions of adhesive and by aerosols, and work in the Establishment's explosion gallery at Buxton on the propagation and prevention of propagation of a coal-dust explosion. The work in the gallery includes an investigation on the dispersion of dust by, and in, the blast from an explosion. An interesting part of that section on explosions deals with the application of gas chromatography followed by a hot-wire detector (or for some purposes an infra-red analyser) for analysis of mine atmospheres, natural gases from boreholes in coal and ironstone mines, fire products and Diesel exhausts.

The section on engineering and metallurgical research shows that light-weight roof-bars were studied during 1956 especially in respect of their stability in temporary support systems at roadheads. Attention was given to the development of convenient and rapid non-destructive methods for checking the soundness of welds in chain links, of particular importance, for example, in cage suspensions. Several failures in ropes and components of couplings and draw gear were examined, and as a result theoretical and experimental work was begun to find improvements in design or in choice of material; photo-elastic methods are being used increasingly in this work. Mining gear may be subjected to corrosion arising from, for example, moist salt spread in mines to bind dust, from acid pit-water, or from the reaction products between salt and acid pit-water. The effects of potentially corrosive materials on mining gear, including wire ropes, were examined during the year and the influence of certain inhibitors was investigated.

As mentioned above, it is not easy to deal adequately in this short notice with the wide variety of work summarized in the report. The report will be read, as the earlier reports of the Establishment have been, with real interest by those connected with the mining industry. It can be recommended, also, to those who are not connected with the mining industry, not only because of the wide range of problems receiving attention but also because several of the problems are similar to those found in other industries.

S. G. Ward

BIOLOGISTS IN THE TROPICS

On July 5 a meeting was arranged by the Institute of Biology to discuss the professional problems of biologists serving overseas. A report of the meeting has been published in the Institute's *Journal* (4, No. 4; 1957). The meeting was opened by Dr. Kenneth Mellanby, lately principal of the University College, Ibadan, Nigeria, who said that many of the economic problems of tropical territories could only be solved by biologists, for whom there are an immense number of fascinating and important problems waiting to be tackled. So far, there has been very little serious biological research in any part of the tropics. Hard-pressed government officials in a number of territories have done much fine work, but shortages of staff and the constant preoccupation with *ad hoc* measures have meant that the fundamental work on which practical measures should be based has not been tackled. At times, the need for such fundamental work has not even been realized; in Nigeria the belief was that there was no need for any work on cocoa and its pests because this was all covered by the work of the Cocoa Research Station in Ghana. There are many more entomologists in Britain studying the wheat bulb fly than there are in West Africa concerned with the pests of cocoa, the mainstay of the economy of Ghana and Western Nigeria.

Dr. E. E. Weatherly, who some years ago worked as a botanist in the Department of Agriculture, Uganda, indicated that there could be no better experience for a biologist of Ph.D. level than that of spending a few years of research in a tropical country. The major professional difficulty in working in tropical parts is that of isolation. First, there is isolation from libraries. To a scientist the library comes second only to the laboratory, but a library is more difficult and expensive to equip and maintain than a laboratory. This difficulty is inherent in spreading out research over isolated and remote stations, for even reasonably useful libraries simply cannot be maintained at such centres.

Next to the absence of books comes the absence of professional colleagues. Except for the very few, discussion of work with others in the same or related fields is a vital stimulus to progress. Few specialists in the tropics can expect such contacts.

Professional isolation has a secondary effect: it can lead only too easily to professional oblivion. The young man overseas, having no opportunity for the self-advertisement provided by conferences and meetings, remains unknown to those of his seniors who might help promote his professional interests.

The greatest problem of all who serve overseas, according to Dr. Weatherly, is education of children. It looms even larger than the purely professional problems, but it inevitably leads to a vital question which is professional in nature. This is the question of length of service. In view of professional and family difficulties, the ideal arrangements would seem to be five, ten or even fifteen years of service, with the opportunity of a return to the United Kingdom when professional or family circumstances demand.

The not-so-young biologist who wishes to resign is confronted with the problem of obtaining a post in the United Kingdom; for this the specialist is better placed than his administrative colleagues. A general agricultural officer is unfit for a return to Britain in proportion to the length of his service. His intimate knowledge of the agriculture, people and climate of an area in Africa is not likely to impress a committee of the Ministry of Agriculture in Britain, or a commercial firm wanting a farm manager.

The difficulties of the biologist research officers wishing to return to the United Kingdom are considerable. For a man who obtains a Colonial Office scholarship immediately after his first degree, the possibility of obtaining a higher degree is precluded. In any event, the type of work carried out in a government department might not be suitable for submission as a thesis. Moreover, his work, although very valuable to his employers and perhaps very valuable as experience to himself, may have led to little publication except in local reports or journals. Then there is the disadvantage of physical remoteness. The head of a department receiving applications for a post is likely to view one from overseas less favourably than others. Nor can the attitude which many senior biologists have to work overseas be precluded. In most branches of biology, tropical experience is not at a premium—it is often regarded as an improper and largely irrelevant version of experience gained in the United Kingdom.

This misconception is rendered possible by the fact that so many senior biologists themselves have never visited, or worked in, the tropics and are in no position to assess the value of tropical experience. Many biologists who have spent some years of successful research in the tropics might reasonably look forward to a biological post in one of the universities in the United Kingdom, but the pattern of university recruitment to-day makes their chances very slender. University teaching has become a profession which may be entered at the bottom, occasionally at the top, but very seldom in the middle.

Finally, there is the problem with which a university tutor is faced in advising students whether to take up tropical work. Is a young man to-day well advised to enter a field of work which seems to be contracting? Self-government in overseas territories and the increasing education of Africans and other peoples up to university-level must inevitably mean fewer posts for Europeans. This would seem to point to scientific careers in the tropics being in many cases rather short, at all events much shorter than thirty years.

Guarantees of security for young men who wish to venture overseas are essential. As biologists they are taking great professional risks and their interests should be safeguarded. Such safeguards are expressed by the Colonial Office in "Reorganization of the Colonial Service, 1954"* as follows: "They will be given adequate notice of any intention to terminate their employment in consequence of constitutional changes, and Her Majesty's Government in the United Kingdom will endeavour to find them alternative employment should they so desire". The word 'endeavour' should be replaced by 'undertake'.

Other contributions to this important meeting were made by D. Rhind, Secretary for Colonial Agricultural Research, who talked about biological research in Colonial territories; Prof. A. H. Bunting, who considered the problems of biologists in the transition of Colonial countries to independence; Prof. G. F. Asprey, who examined the problems of biologists in university colleges overseas, and Prof. R. D. Purchon, of the University of Malaya, who was particularly concerned with the problems of his own university.

TRADE WASTES

As a result of public demand for the abatement of pollution of rivers, the River Boards Act, 1948, and the Rivers (Prevention of Pollution) Act, 1951, all those concerned with the disposal of polluting liquids, and particularly industrialists and local authorities, have found it necessary in recent years to give serious consideration to the development of efficient methods of treating such liquids to reduce their polluting character. During the past three years, several symposia on industrial effluents have been held in Britain, and a report has been issued* on the proceedings of a successful and well-attended symposium held by the Midland Branch of the Institute of Sewage Purification at the University of Birmingham on April 9, 1957. The chairman was Dr. A. Key, senior chemical inspector, Ministry of Housing and Local Government, and the proceedings were opened by Alderman A. Paddon Smith, chairman of the Birmingham Tame and Rea District Drainage Board. The papers presented dealt with the problems concerned with acceptance of trade effluents into public sewers, the obligations imposed on local authorities and traders by the rivers pollution prevention Acts, and methods of treatment of particular waste waters.

Mr. M. A. Kershaw, in a paper on the first of these subjects, makes the point that one of the effects of industrial expansion is the aggravated pollution problem occasioned by increased volumes of trade effluent, frequently of a highly complex character. He accepts the view that trade effluents are best disposed of by discharge to the public sewers, provided that treatment is applied to the effluents so that they will not damage the sewers, or cause danger to workmen, or interfere with the processes of purification of sewage. Methods of removing constituents most likely to cause difficulty are outlined, and an organized system of trade effluent inspection and control operated by the local authority is advocated to ensure co-operation between the authority and manufacturers.

---

* Symposium on Trade Wastes held at the University of Birmingham. Pp. 167. (London: Joint Secretaries, Institute of Sewage Purification, 1957.) 10s.

Dealing with the obligations imposed by the pollution prevention Acts, Mr. M. Lovett directs attention to the fact that, although during the interim period of seven years after the passing of the 1951 Act a river board may not, without the consent of the Minister of Housing and Local Government, institute legal proceedings against a person who "causes or knowingly permits to enter a stream any poisonous, noxious or polluting matter", the consent of the Minister is not required for proceedings against an offender who fails to comply with valid conditions of consent relating to a new discharge. A new feature which is referred to is that river boards may now 'apprehend' that a contravention of the Act is likely to occur as a result of a proposed use of a stream, and, subject to the consent of the Minister during the interim period, may obtain an order prohibiting the use complained of. The author, however, emphasizes that river boards are much more anxious to abate pollution than to institute legal proceedings.

In four of the five examples of methods of treatment of industrial organic wastes brought together by Dr. D. H. Sharp, biological oxidation forms the final stage, after preliminary chemical and physical treatment to remove substances which would otherwise interfere with biological action. Perhaps the most interesting of these preliminary treatments is that applied to the waste water from the manufacture of pesticides. These contain bactericidal and toxic compounds which are removed partly by adsorption on activated charcoal and partly by chemical precipitation before the neutralized and diluted waste is applied to percolating filters.

The paper on acid wastes by Dr. S. H. Jenkins and Mr. C. H. Hewitt is of particular interest in the Birmingham district, where a great deal of metal working is done, with consequent discharge of acid liquors and washings from preliminary pickling of the metal. Examples of acid discharges are quoted which reduced the pH value of sewage reaching a treatment works to less than 3 for several hours. At this degree of acidity damage to the sewer occurs, the conversion of urea to ammonia is inhibited, and there is serious depression of the biological activity on which purification of sewage depends. Neutralization of acid discharges is therefore essential, and the authors describe (with illustrations) a range of neutralization plants of different sizes and designs.

Discharge of electro-plating wastes is also very common in the Midlands, and in a paper on treatment of these liquids Mr. A. E. J. Pettet stresses the need to consider conservation of water and chemicals in the plating shop before treatment of wastes unavoidably discharged is undertaken. Chemical methods of oxidation, reduction or precipitation are usually used for treatment, but cyanides can be destroyed biologically. Waste chromic acid anodizing solutions can be regenerated for re-use by means of recently developed ion-exchange resins resistant to the action of this acid.

The disposal of gas works effluents, dealt with by Mr. W. T. Lockett, is a problem of national concern, and investigators in the Midlands are particularly active in seeking a solution. The author traces the changing nature of the problem from the time when horizontal gas retorts were in use, ammonia was worth recovering from the liquor, and each gas works served a restricted area, to the present day when vertical retorts are most commonly used, ammonia can be recovered only at a loss, and small gas works are being superseded by centralized works serving large areas. Investigations fifty years ago showed that gas liquor could be treated biologically, the researches of the Institution of Gas Engineers during 1928–37 defined the conditions under which gas liquor could be satisfactorily treated when mixed with sewage, and revealed that certain changes in the operation of gas works could make treatment easier, and present-day researches are concerned with both chemical and high-rate biological methods of treatment.

Much discussion, reported in a separate booklet, centred around the mode of application of the 1937, 1948 and 1951 Acts and the cost to manufacturers and local authorities of treating industrial effluents. It was urged that by alteration of processes and by using conservation methods within factories, water and valuable materials could be saved and the cost and difficulty of treatment could be much reduced. Among examples quoted were that in one factory waste sulphonation acid was reconcentrated to give a crude but saleable product, and that in another small factory 10,000 gallons of water were saved a day by alteration of process and by introduction of a re-circulatory water system. A. E. J. Pettet

BASIC RESEARCH IN THE UNITED STATES
